$\square$

The MC33304 is a monolithic bipolar operational amplifier. This low voltage rail-to-rail amplifier has both a rail-to-rail input and output stage, with high output current capability. This amplifier also employs Sleep-Mode technology. In sleepmode, the micropower amplifier is active and waiting for an input signal. When a signal is applied, causing the amplifier to source or sink $\geq 200 \mu \mathrm{~A}$ (typically) to the load, it will automatically switch to the awakemode (supplying up to 70 mA to the load). When the output current drops below $90 \mu \mathrm{~A}$, the amplifier automatically returns to the sleepmode.

Excellent performance can be achieved as an audio amplifier. This is due to the amplifier's low noise and low distortion. A delay circuit is incorporated to prevent crossover distortion.

- Ideal for Battery Applications
- Full Output Signal (No Distortion) for Battery Applications Down to $\pm 0.9$ VDC.
- Single Supply Operation (+1.8 to +12 V)
- Rail-To-Rail Performance on Both the Input and Output
- Output Voltages Swings Typically within 100 mV of Both Rails ( $R_{L}=1.0 \mathrm{~m} \Omega$ )
- Two States: "Sleepmode" (Micropower, ID $=110 \mu \mathrm{~A} / \mathrm{Amp}$ ) and "Awakemode" (High Performance, ID = $1200 \mu \mathrm{~A} /$ Amp)
- Automatic Return to Sleepmode when Output Current Drops Below Threshold, Allowing a Fully Functional Micropower Amplifier
- Independent Sleepmode Function for Each Amplifier
- No Phase Reversal on the Output for Overdriven Input Signals
- High Output Current ( 70 mA typically)
- $600 \Omega$ Drive Capability
- Standard Pinouts; No Additional Pins or Components Required
- Drop-In Replacement for Many Other Quad Operational Amplifiers
- Similar to MC33201, MC33202 and MC33204 Family
- The MC33304 Amplifier is Offered in the Plastic DIP or SOIC Package (P and D Suffixes)

Sleep-Mode is a trademark of Motorola, Inc.

NOTES: 1. The differential input voltage of each amplifier is limited by two internal diodes. The diodes are connected across the inputs in parallel and opposite to each other. For more differential input voltage range, use current limiting resistors in series with the input pins.
2. The common-mode input voltage range of each amplifier is limited by diodes connected from the inputs to both power supply rails. Therefore, the voltage on either input must not exceed supply rail by more than $\pm 500 \mathrm{mV}$.
3. Simultaneous short circuits of two or more amplifiers to the positive or negative rail can exceed the power dissipation ratings and cause eventual failure of the device.
4. Rail-to-rail performance is achieved at the input of the amplifier by using parallel NPN-PNP differential stages. When the inputs are near the negative rail ( $\mathrm{V}_{\mathrm{EE}}<\mathrm{V}_{\mathrm{CM}}<800 \mathrm{mV}$ ), the PNP stage is on. When the inputs are above 800 mV (i.e. $800 \mathrm{mV}<\mathrm{V}_{\mathrm{CM}}<\mathrm{V}_{\mathrm{CC}}$ ), the NPN stage is on. This switching of the input pairs will cause a reversal of input bias current. Slight changes in the input offset voltage will be noted between the NPN and PNP pairs. Cross-coupling techniques have been used to keep this change to a minimum.
5. Power dissipation must be considered to ensure maximum junction ( $T_{J}$ ) is not exceeded. (See Figure 2)
6. When connected as a voltage follower and used in transient conditions, a current limiting resistor may be needed between the output and the inverting input. This is because of the back to back diodes clamped across the inputs. The value of this resistor should be between $1.0 \mathrm{k} \Omega$ and $10 \mathrm{k} \Omega$. If the amplifier does not become slew rate limited and is processing low frequency waveforms, then no resistor would be necessary. (The output could be tied directly to the negative input.)

There are 515 active components for the entire quad device.

## MC33304 <br> DEVICE DESCRIPTION

The MC33304 will begin to function at power supply voltages as low as $\mathrm{V}_{\mathrm{S}}= \pm 0.8 \mathrm{~V}$. The device has the ability to swing rail-to-rail on both the input and the output. Since the common mode input voltage range extends from $\mathrm{V}_{\mathrm{CC}}$ to $\mathrm{V}_{\mathrm{EE}}$, it can be operated with either single or split voltage supplies. The MC33304 is guaranteed not to latch up or phase reverse over the entire common mode range. However, the output could go into phase reversal state if input voltage is set higher than $+\mathrm{V}_{\mathrm{CC}}$ or $-\mathrm{V}_{\mathrm{EE}}$.

When power is initially applied, the part may start to operate in the awakemode. This occurs because of bias currents being generated from the charging of the internal capacitors. When this occurs, the user will have to wait approximately 1.5 seconds before the device will switch back to the sleepmode.

The amplifier is designed to switch from sleepmode to awakemode whenever the output current exceeds a preset current threshold (ITH) of approximately $200 \mu \mathrm{~A}$. As a result, the output switching threshold voltage $\left(\mathrm{V}_{\mathrm{ST}}\right)$ is controlled by the output loading resistance ( $\mathrm{R}_{\mathrm{L}}$ ). Large valued load resistors require a large output voltage to switch, but reduce unwanted transitions to the awakemode.

Most of the transition time is consumed slewing in the sleepmode until $\mathrm{V}_{\mathrm{S}}$ is reached, therefore, small values of $\mathrm{R}_{\mathrm{L}}$ allow rapid transition to the awakemode. The output switching threshold voltage ( $\mathrm{V}_{\mathrm{ST}}$ ) is higher for the larger values of $R_{L}$, requiring the amplifier to slew longer in the slower sleepmode state before switching to the awakemode.

Although typically $200 \mu \mathrm{~A}$, ITH varies with supply voltage, temperature and the load resistance. Generally, any current loading on the ouput which causes a current greater than ITH
to flow will switch the amplifier into the awakemode. This includes transition currents like those generated by charging load capacitances. In fact, the maximum capacitance that can be driven while attempting to remain in the sleepmode is approximately 300 pF .

The awakemode to sleepmode transition time is controlled by an internal delay circuit, which is necessary to prevent the amplifier from going to sleep during every zero crossing of the output waveform. This delay circuit also eliminates the crossover distortion commonly found in micropower amplifiers.

The MC33304 rail-to-rail sleepmode operational amplifier is unique in its ability to swing rail-to-rail on both the input and output using a bipolar design. This offers a low noise and wide common mode input voltage range. Since the common mode input voltage range extends from $\mathrm{V}_{\mathrm{CC}}$ to $\mathrm{V}_{\mathrm{EE}}$, it can be operated with either single or split voltage supplies.

Rail-to-rail performance is achieved at the input of the amplifiers by using parallel NPN-PNP differential input stages. When the inputs are within 800 mV of the negative rail, the PNP stage is on. When the inputs are more than 800 mV above VEE, the NPN stage is on. This switching of input pairs will cause a reversal of input bias currents. Also, slight differences in offset voltage may be noted between the NPN and PNP pairs. Cross-coupling techniques have been used to keep this change to a minimum.

In addition to the rail-to-rail performance, the output stage is current boosted to provide enough output current to drive $600 \Omega$ loads. Because of this high current capability, care should be taken not to exceed the $150^{\circ} \mathrm{C}$ maximum junction temperature specification.
