## **TDA9141** PAL/NTSC/SECAM decoder/sync processor

Product specification  
File under Integrated Circuits, IC02

December 1992

**PAL/NTSC/SECAM decoder/sync processor****TDA9141****FEATURES**

- Multistandard PAL, NTSC and SECAM
- I<sup>2</sup>C-bus controlled
- I<sup>2</sup>C-bus addresses can be selected by hardware
- Alignment free
- Few external components
- Designed for use with baseband delay lines
- Integrated video filters
- CVBS or YC input with automatic detection
- CVBS output
- Vertical divider system
- Two-level sandcastle signal
- V<sub>A</sub> synchronization pulse (3-state)
- H<sub>A</sub> synchronization pulse or clamping pulse CLP input/output
- Line-locked clock output or stand-alone I<sup>2</sup>C-bus output port
- Stand-alone I<sup>2</sup>C-bus input/output port
- Colour matrix and fast YUV switch
- Comb filter enable input/output with subcarrier frequency.

**GENERAL DESCRIPTION**

The TDA9141 is an I<sup>2</sup>C-bus controlled, alignment-free PAL/NTSC/SECAM decoder/sync processor. The TDA9141 has been designed for use with baseband chrominance delay lines, and has a combined subcarrier frequency/comb filter enable signal for communication with a PAL comb filter.

The IC can process CVBS signals and Y/C input signals. The input signal is available on an output pin, in the event of a Y/C signal, it is added into a CVBS signal.

The sync processor provides a two-level sandcastle, a horizontal pulse (CLP or H<sub>A</sub> pulse, bus selectable) and a vertical (V<sub>A</sub>) pulse. When the H<sub>A</sub> pulse is selected a line-locked clock (LLC) signal is available at the output port pin.

A fast switch can select either the internal Y signal with the UV input signals, or YUV signals made of the RGB input signals. The RGB input signals can be clamped with either the internal or an external clamping signal (search tuning mode).

Two pins with an input/output port and an output port of the I<sup>2</sup>C-bus are available.

The I<sup>2</sup>C-bus address of the TDA9141 is hardware programmable.

# PAL/NTSC/SECAM decoder/sync processor

TDA9141

## FUNCTIONAL DESCRIPTION

### General

The TDA9141 is an I<sup>2</sup>C-bus controlled, alignment-free PAL/NTSC/SECAM colour decoder/sync processor which has been designed for use with baseband chrominance delay lines.

In the standard operating mode the I<sup>2</sup>C-bus address is 8A. If the address input is connected to the positive rail the address will change to 8E.

### Input switch

**WARNING: THE VOLTAGE ON THE CHROMINANCE PIN MUST NEVER EXCEED 5.5 V. IF IT DOES THE IC ENTERS A TEST MODE.**

The TDA9141 has a two pin input for CVBS or YC signals which can be selected via the I<sup>2</sup>C-bus. The input selector also has a position in which it automatically detects whether a CVBS or YC signal is on the input. In this input selector position, standard identification first takes place on an added Y/CVBS and C input signal. After that, both chrominance signal input amplitudes are checked once and the input with the strongest chrominance burst signal is selected. The input switch status is read out by the I<sup>2</sup>C-bus via output bit YC.

### CVBS output

In the standard operating mode with the I<sup>2</sup>C-bus address 8A, a CVBS output signal is available on the address pin, which represents either the CVBS input signal or the Y/C input signal, added into a CVBS signal

### RGB colour matrix

**WARNING: THE VOLTAGE ON THE UIN PIN MUST NEVER EXCEED 5.5 V. IF IT DOES THE IC ENTERS A TEST MODE.**

The TDA9141 has a colour matrix to convert RGB input signals into YUV signals. A fast switch, controlled by

the signal on pin F and enabled by the I<sup>2</sup>C-bus via EFS (enable fast switch), can select between these YUV signals and the YUV signals of the decoder. The Y signal is internally connected to the switch. The  $-(R-Y)$  and  $-(B-Y)$  output signals of the decoder have to first be delayed in external baseband chrominance delay lines. The outputs of the delay lines must be connected to the UV input pins. If the RGB signals are not synchronous with the selected decoder input signal, clamping of the RGB input signals is possible by I<sup>2</sup>C-bus selection of STM (search tuning mode), EFS and by feeding an external clamping signal to the CLP pin.

Also in search tuning mode the VA output will be in a high impedance OFF-state.

### Standard identification

The standards which the TDA9141 can decode are dependent on the choice of external crystals. If a 4.4 MHz and a 3.6 MHz crystal are used then SECAM, PAL 4.4/3.6 and NTSC 4.4/3.6 can be decoded. If two 3.6 MHz crystals are used then only PAL 3.6 and NTSC 3.6 can be decoded. Which 3.6 MHz standards can be decoded is dependent on the exact frequencies of the 3.6 MHz crystals. In an application where not all standards are required only one crystal is sufficient (in this instance the crystal must be connected to the reference crystal input (pin 30)). If a 4.4 MHz crystal is used it must always be connected to pin 30. Both crystals are used to provide a reference for the filters and the horizontal PLL, however, only the reference crystal is used to provide a reference for the SECAM demodulator.

To enable the calibrating circuits to be adjusted exactly two bits from I<sup>2</sup>C-bus subaddress 00 are used to indicate which crystals are connected to the IC.

The standard identification circuit is a digital circuit without external components; the search loop is illustrated in Fig.3.

The decoder (via the I<sup>2</sup>C-bus) can be forced to decode either SECAM or PAL/NTSC (but not PAL or NTSC). Crystal selection can also be forced. Information concerning which standard and which crystal have been selected and whether the colour killer is ON or OFF is provided by the read out. Using the forced-mode does not affect the search loop, it does, however, prevent the decoder from reaching or staying in an unwanted state. The identification circuit skips impossible standards (e.g. SECAM when no 4.4 MHz crystal is fitted) and illegal standards (e.g. is forced mode). To reduce the risk of wrong identification PAL has priority over SECAM (only line identification is used for SECAM).

### Integrated filters

All filters, including the luminance delay line, are an integral part of the IC. The filters are gyrator-capacitor type filters. The resonant frequency of the filters is controlled by a circuit that uses the active crystal to tune the SECAM Cloche filter during the vertical flyback time. The remaining filters and the luminance delay line are matched to this filter. The filters can be switched to either 4.43 MHz, 4.28 MHz or 3.58 MHz irrespective of the frequency of the active crystal. The switching is controlled by the identification circuit.

In YC mode the chrominance notch filter is bypassed, to preserve full signal bandwidth.

For a CVBS signal the chrominance notch filter can be bypassed by I<sup>2</sup>C-bus selection of TB (trap bypass). The luminance delay line delivers the Y signal to the output 60 ns after the  $-(R-Y)$  and  $-(B-Y)$  signals have arrived at their outputs.

## PAL/NTSC/SECAM decoder/sync processor

TDA9141

This compensates for the delay of the external chrominance delay lines.

### Colour decoder

The PAL/NTSC demodulator employs an oscillator that can operate with either crystal (3.6 or 4.4 MHz). If the I<sup>2</sup>C-bus indicates that only one crystal is connected it will always connect to the crystal on the reference crystal input (pin 30).

The Hue signal, which is adjustable via the I<sup>2</sup>C-bus, is gated during the burst for NTSC signals.

The SECAM demodulator is an auto-calibrating PLL demodulator which has two references. The reference crystal, to force the PLL to the desired free-running frequency and the bandgap reference, to obtain the correct absolute value of the output signal. The VCO of the PLL is calibrated during each vertical blanking period, when the IC is in search mode or SECAM mode. If the reference crystal is not 4.4 MHz the decoder will not produce the correct SECAM signals.

The frequency of the active crystal is fed to the Fscomb output, which can be connected to an external comb filter IC. The DC value on this pin contains the comb enable information. Comb enable is true when bus bit ECMB is HIGH. If ECMB is LOW, the subcarrier frequency is suppressed. The external comb filter can force the DC value of Fscomb LOW, as pin Fscomb also acts as input pin. In this event the subcarrier frequency is still present. If the DC value of Fscomb is HIGH, the input switch is always forced in Y/C mode, indicated by bus bit YC.

### Sync processor ( $\phi 1$ loop)

The main part of the sync circuit is a  $432 \times f_H$  (6.75 MHz) oscillator the frequency of which is divided by 432 to lock the Phase 1 loop to the incoming signal. The time constant of the loop can be forced by the I<sup>2</sup>C-bus (fast or slow). If required the IC can select the time constant, depending on the noise content of the input signal and whether the loop is phase-locked or not (medium or slow). The free-running frequency of the oscillator is determined by a digital control circuit that is locked to the active crystal.

When a power-on-reset pulse is detected the frequency of the oscillator is switched to a frequency greater than 6.75 MHz to protect the horizontal output transistor. The oscillator frequency is reset to 6.75 MHz when the crystal indication bits have been loaded into the IC. To ensure that this procedure does not fail it is absolutely necessary to send subaddress 00 before subaddress 01. Subaddress 00 contains the crystal indication bits and when subaddress 01 is received the line oscillator calibration will be initiated (for the start-up procedure after power-on reset detection see the I<sup>2</sup>C-bus protocol). The calibration is terminated when the oscillator frequency reaches 6.75 MHz. The oscillator is again calibrated when an out-of-lock condition with the input signal is detected by the coincidence detector. Again the calibration will be terminated when the oscillator frequency reaches 6.75 MHz. The Phase 1 loop can be opened using the I<sup>2</sup>C-bus. This is to facilitate On Screen Display (OSD) information. If there is no input signal or a very noisy input signal the phase 1 loop can be opened to provide a stable line frequency and thus a stable picture.

The sync part also delivers a two-level sandcastle signal, which provides a combined horizontal and vertical blanking signal and a clamping pulse for the display section of the TV.

### Vertical divider system

The vertical divider system has a fully integrated vertical sync separator. The divider can accommodate both 50 and 60 Hz systems; it can either locate the field frequency automatically or it can be forced to the desired system via the I<sup>2</sup>C-bus. A block diagram of the vertical divider system is illustrated in Fig.4. The divider system operates at twice the horizontal line frequency. The line counter receives enable pulses at this line frequency, thereby counting two pulses per line.

A state diagram of the controller is illustrated in Fig.5. Because it is symmetrical only the right hand part will be described.

Depending on the previously found field frequency, the controller will be in one of the COUNT states. When the line counter has counted 488 pulses (i.e. 244 lines of the video input signal) the controller will move to the next state depending on the output of the norm counter. This can be either NORM, NEAR\_NORM or NO\_NORM depending on the position of the vertical sync pulse in the previous fields. When the controller is in the NORM state it generates the vertical sync pulse (VSP) automatically and then, when the line counter is at  $LC = 626$ , moves to the WAIT state. In this condition it waits for the next pulse of the double line frequency signal and then moves to the COUNT state of the current field frequency. When the controller returns to the COUNT state the line counter will be reset half a line after the start of the vertical sync pulse of the video input signal.

---

## PAL/NTSC/SECAM decoder/sync processor

---

TDA9141

When the controller is in the NEAR\_NORM state it will move to the COUNT state if it detects the vertical sync pulse within the NEAR\_NORM window (i.e.  $622 < LC < 628$ ). If no vertical sync pulse is detected, the controller will move back to the COUNT state when the line counter reaches  $LC = 628$ . The line counter will then be reset.

When the controller is in the NO\_NORM state it will move to the COUNT state when it detects a vertical sync pulse and reset the line counter. If a vertical sync pulse is not detected before  $LC = 722$  (if the Phase 1 loop is locked in forced mode) it will move to the COUNT state and reset the line counter. If the Phase 1 loop is not locked the controller will move back to the COUNT state when  $LC = 628$ . The forced mode option keeps the

controller in either the left-hand side (60 Hz) or the right-hand side (50 Hz) of the state diagram.

Figure 6 illustrates the state diagram of the norm counter which is an up/down counter that counts up if it finds a vertical sync pulse within the selected window. In the NEAR\_NORM and NORM states the first correct vertical sync pulse after one or more incorrect vertical sync pulses is processed as an incorrect pulse. This procedure prevents the system from staying in the NEAR\_NORM or NORM state if the vertical sync pulse is correct in the first field and incorrect in the second field. If no vertical sync pulse is found in the selected window this will always result in a down pulse for the norm counter.

### Output port and input/output port

Two stand-alone ports are available for external use. These ports are I<sup>2</sup>C-bus controlled, the output port by bus bit OPB and the input/output port by bus bit OPA. Bus bit OPA is an open-drain output, to enable input port functioning. The pin status is read out by bus via output bit IP.

### Sandcastle

Figure 7 illustrates the timing of the acquisition sandcastle (ASC) and the  $V_A$  pulse with respect to the input signal. The sandcastle signal is in accordance with the 2-level 5 V sandcastle format. An external vertical guard current can overrule the sink current to enable blanking purposes.

**I<sup>2</sup>C-bus protocol**

If the address input is connected to the positive supply the address will change from 8A to 8E.

Valid subaddresses = 00 to 0F

Auto-increment mode available for subaddresses.

**Start-up procedure:** read the status byte until POR = 0; send subaddress 00 with the crystal indicator bits (XA and XB) indicating that only one crystal is connected to the IC; wait for 250 ms; send subaddress 01; wait for at least 100 ms; set XA, XB to the actual crystal configuration.

Each time before the data in the IC is refreshed, the status byte must be read. If POR = 1, then the above procedure must be carried out to restart the IC.

Failure to stick to the above procedure may result in an incorrect line frequency after power-up or a power-dip.

**Notes to the characteristics**

- All oscillator specifications are measured with the Philips crystal series 4322 143/144. If the spurious response of the reference crystal is less than –3 dB with respect to the fundamental frequency for a damping resistance of 1 kΩ, oscillation at the fundamental frequency is guaranteed. The spurious response of the second crystal must be less than –3 dB with respect to the fundamental frequency for a damping resistance of 1.5 kΩ.  
The catching and detuning range are measured for nominal crystal parameters. These are:  
load resonance frequency  $f_0$  ( $C_L = 20$  pF) = 4.433619 MHz, (second crystal: 3.579545 MHz)  
motional capacitance  $C_M = 20.6$  fF, (second crystal: 14.7 fF)  
parallel capacitance  $C_0 = 5.5$  pF, (second crystal: 4.5 pF).  
The actual load capacitance in the application should be  $C_L = 18$  pF to account for parasitic capacitances on and off chip.
- This delay is caused by the low pass filter at the sync separator input.
- The output signals of the demodulator are called –(R–Y) and –(B–Y). The colour difference input and output signals of the YUV switch are called UV signals. However, these signals do not have the amplitude correction factor of real UV signals. They are called UV signals and not –(R–Y) and –(B–Y) to prevent confusion between the colour difference signals of the demodulator and the colour difference signals of the YUV switch.
- This value refers to signals including a sync pulse. For Y signals composed to the RGB inputs this output voltage is 30% lower, as there is no sync pulse on such signals.

PAL/NTSC/SECAM decoder/sync processor

TDA9141

QUALITY SPECIFICATION

Quality level in accordance with URV 4-2-59/601.

TEST AND APPLICATION INFORMATION

Fig.8 Application diagram.

Notes to figure 8

1. Pins 28 and 32 are sensitive to leakage current.
2. The analog and digital ground currents should be completely separated.
3. The decoupling capacitor connected between pins 8 and 9 must be placed as close to the IC as possible.

## PAL/NTSC/SECAM decoder/sync processor

TDA9141

### SOLDERING

#### Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our "IC Package Databook" (order code 9398 652 90011).

#### Soldering by dipping or by wave

The maximum permissible temperature of the solder is 260 °C; solder at this temperature must not be in contact

with the joint for more than 5 seconds. The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature ( $T_{stg\ max}$ ). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

#### Repairing soldered joints

Apply a low voltage soldering iron (less than 24 V) to the lead(s) of the package, below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than 300 °C it may remain in contact for up to 10 seconds. If the bit temperature is between 300 and 400 °C, contact may be up to 5 seconds.

### DEFINITIONS

<b>Data sheet status</b>	
Objective specification	This data sheet contains target or goal specifications for product development.
Preliminary specification	This data sheet contains preliminary data; supplementary data may be published later.
Product specification	This data sheet contains final product specifications.
<b>Limiting values</b>	
Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.	
<b>Application information</b>	
Where application information is given, it is advisory and does not form part of the specification.	

### LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.

### PURCHASE OF PHILIPS I<sup>2</sup>C COMPONENTS

Purchase of Philips I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C system provided the system conforms to the I<sup>2</sup>C specification defined by Philips. This specification can be ordered using the code 9398 393 40011.
