

**LB1875****Polygon Mirror Motor Predriver IC****Overview**

The LB1875 is a predriver IC for polygon mirror motors. By using a driver array or discrete transistors (FETs) at the output, motor drive with high rotation precision is possible. PAM drive or direct PWM drive can be selected for the output to realize high-efficiency control with minimum power loss.

**Features**

- Three-phase bipolar drive
- Direct PWM drive (bottom side) or PAM drive selectable
- PLL speed control circuit
- PWM oscillator
- Quartz oscillator
- Frequency divider
- FG with Schmitt comparator
- FG input single edge, dual edge selector circuit
- Integrating amplifier
- Phase lock detector output
- Current limiter
- Motor lock protection
- Thermal protection
- Forward/reverse circuit
- 5V regulator output

**Package Dimensions**

unit: mm

**3235-HSOP36**

- Any and all SANYO products described or contained herein do not have specifications that can handle applications that require extremely high levels of reliability, such as life-support systems, aircraft's control systems, or other applications whose failure can be reasonably expected to result in serious physical and/or material damage. Consult with your SANYO representative nearest you before using any SANYO products described or contained herein in such applications.
- SANYO assumes no responsibility for equipment failures that result from using products at values that exceed, even momentarily, rated values (such as maximum ratings, operating condition ranges, or other parameters) listed in products specifications of any and all SANYO products described or contained herein.

**Block Diagram and Sample Application Circuit  
(Sample application: PAM drive, FET output)**

A11596

Note: For applications where the motor has variable speed and control at low motor voltages is required, the base voltage of the output interface transistor must be made low. In this case, a P-channel FET which can be used at low gate voltages must be selected.

(Sample application: direct PWM drive, FET output)

A11597

(Sample application: PAM drive, bipolar transistor output)

A11598

## Description of the LB1875

### 1. Speed control circuit

This IC uses the PLL speed control technique which allows stable, high-precision motor rotation with low jitter. The PLL circuit performs phase comparison of the falling edge of the clock input (CLK<sub>IN</sub>) with the edge of the FG input. Control is based on the differential output.

When the FG<sub>SEL</sub> pin is Low, only the falling edge of the FG signal is valid. When the pin is High or open, both edges are valid. When both edges are used, the FG waveform precision becomes critical.

When using an external clock input (supplied from CLK<sub>IN</sub> pin), the FG servo frequency is determined by the following equation.

$$f_{FG}(\text{servo}) = f_{CLK} \quad (\text{FG}_{SEL} = \text{Low})$$

$$f_{FG}(\text{servo}) = f_{CLK}/2 \quad (\text{FG}_{SEL} = \text{High or open})$$

When using the internal clock, the FG servo frequency is determined by the following equation. The number of FG pulses and the quartz oscillator frequency determine the motor rotation speed.

$$f_{FG}(\text{servo}) = f_{OSC}/N \quad (\text{FG}_{SEL} = \text{Low})$$

$$f_{FG}(\text{servo}) = f_{OSC}/2N \quad (\text{FG}_{SEL} = \text{High or open})$$

$f_{OSC}$ : Quartz oscillator frequency

N: Clock divisor (see table)

### 2. Output drive

This IC allows selection of PAM drive or direct PWM drive.

When the LIM pin is Low, the direct PWM mode is selected. The ON duty cycle of the UH, VH, and WH output (external bottom-side transistor drive output) changes, thereby controlling the motor speed. Current control is also realized by changing the ON duty cycle to limit the current. At this time, the Schmitt comparator output of the FG is supplied at the PWM<sub>OUT</sub> pin. When bipolar transistors are used externally, the top-side transistors should not have an integrated diode, but Schottky barrier diodes should be used instead (to prevent feedthrough current caused by diode reverse recovery during PWM switching).

When the LIM pin is High or open, the PAM drive mode is selected. The PWM<sub>OUT</sub> pin carries the PWM signal. This output can drive an external switching regulator circuit for varying the motor supply voltage and thereby controlling motor speed. Current control is also realized by changing the motor supply voltage. In this case, a delay in the switching regulator circuit will cause a delay in the current control action. During the delay, a higher current than the set current may flow, which must be taken into consideration when selecting output transistors. For applications where the motor has variable speed and control at low motor voltages is required, the lowest operation voltage is limited by the base voltage of the interface transistor for top-side output transistor drive. If this causes a problem, the base voltage must be made low (for example by dividing the V<sub>REG</sub> voltage with resistors). When FETs are used as top-side output transistors, types which can be used at low gate voltages must be selected.

### 3. Current limiting circuit

The current limiting circuit limits the peak current to the value  $I = V_{RF}/R_f$  ( $V_{RF} = 0.5V$  typ.,  $R_f$ : current detector resistor). As mentioned above, in PAM drive mode, a current higher than the set current may flow during the delay interval. If the capacitor charge current of the switching regulator circuit is a problem, a smoothing capacitor may be inserted, with the negative side connected to the RF pin.

If PWM noise is a problem in the RF waveform, a filter should be provided at the input.

4. Reference clock

Since the clock input of the PLL circuit (CLK<sub>IN</sub>) and the internal divisor output (CLK<sub>OUT</sub>) are separate, various applications are possible.

(1) Using the internal divider circuit

Basically, CLK<sub>IN</sub> and CLK<sub>OUT</sub> are shorted. If a division ratio other than the built-in ratio is required, an external divider circuit can be inserted between these two pins.

[1] Using a quartz oscillator

An oscillator using a quartz crystal and C, R components can be configured as shown below.

- C1, R1 : For stable oscillation
- C2 : For overtone oscillation prevention
- C3 : For crystal coupling

A11349

(Reference values)

Oscillator frequency (MHz)	C1 (μF)	C2 (pF)	C3 (pF)	R1 ( Ω)
2 to 3	0.1	10	100	330k
3 to 7	0.1	None	47	330k
7 to 9	0.1	None	22	330k
9 to 10	0.1	None	12	330k

The circuit configuration and values are for reference only. The quartz crystal characteristics as well as the possibility of floating capacitance and noise due to layout factors must be taken into consideration when designing an actual application.

[Precautions for wiring layout design]

Since the quartz oscillator circuit operates at high frequencies, it is susceptible to the influence of floating capacitance from the circuit board. Wiring should be kept as short as possible and traces should be kept narrow.

[2] External clock input (equivalent to quartz oscillator, several MHz)

When using an external signal source instead of a quartz oscillator, a resistor of about 13 kΩ should be inserted in series at the Xi input. The Xo pin should be left open.

Signal input level

- Low: 0 to 0.8 V
- High: 2.5 to 5 V

(2) When not using the internal divider circuit

When using an external signal source to supply a signal equivalent to the FG frequency (several kHz), the signal is input via the CLK<sub>IN</sub> pin. When not using a quartz oscillator, the Xi pin should be left open or connected to the V<sub>REG</sub> pin (Xo is open).

5. Hall input signal

The Hall input requires a signal with an amplitude of at least the hysteresis width (24 mV max.). Taking possible noise influences into consideration, an amplitude of at least 100 mV is desirable. If noise at the Hall input is a problem, a noise-canceling capacitor (about 0.001 to 0.1 μF) should be connected across the Hall input pins .

Since the same-phase input range is 0 to V<sub>CC</sub>-2V, a Hall element can be connected in series if 12V is applied at the V<sub>CC</sub> pin.

6. FG input signal

The FG input is designed mainly for input from a Hall element and has the same specifications as the Hall input. If the input is to be used for an FG pattern or other very low-level signal, an external amplifier must be used to amplify the signal first.

When there is noise at the FG input, locking may be impaired and jitter may increase. If PWM switching noise or other noise is found to be present, countermeasures such as making the Hall element power supply more stable or connecting a capacitor across the input will be necessary.

### 7. PWM frequency

The PWM frequency is determined by the capacitance connected to the  $C_{PWM}$  pin.

$$f_{PWM} \doteq 1/(15000 \times C)$$

The PWM frequency should be between 15 and 50 kHz. If the frequency is too low, noise and control performance may be a problem. If it is too high, switching losses will increase.

### 8. LD output

The LD1 output is ON when phase lock is achieved. Phase lock is evaluated only by the phase (through edge comparison), not by speed deviation. Therefore when LD1 is ON, speed deviation is affected by the FG signal acceleration for example when establishing the lock condition. (The lower the acceleration, the lower the speed deviation.) When it is necessary to limit speed deviation when LD1 is ON, the results of actual motor speed measurement must be applied.

### 9. Power supply

When using FETs as bottom-side output transistors, applying a voltage of 12V to the  $V_{CC}$  pin makes it possible to supply a gate voltage of about 10V. When using FETs or bipolar transistors that can handle a low gate voltage, the  $V_{CC}$  and  $V_{REG}$  pins can also be short-circuited to apply 5V. (In this case, do not apply voltage higher than 5.5V.)

Since this IC is designed for use in high-current motors, the power supply line may fluctuate easily. Therefore a capacitor of sufficient capacitance must be provided between the  $V_{CC}$  pin and ground, to assure stable operation. If a diode is used in the power line for reverse-connection protection, power line fluctuations may be further increased, which will require more capacitance.

### 10. Motor lock protection circuit

To protect the IC and the motor itself when rotation is inhibited, a motor lock protection circuit is provided. If the LD output is High (unlocked) for a certain interval in the start condition, the external bottom-side transistors are turned off. The length of the interval is determined by the capacitance at the CSD pin. A capacitance of 0.1  $\mu$ F results in a trigger interval of about 10 seconds.

$$\text{Trigger interval (S)} \doteq 110 \times C (\mu\text{F})$$

The trigger interval should be set so as to leave sufficient leeway for motor startup. Speed reduction due to clock frequency switching does not trigger the protection circuit.

When the protection circuit has been triggered, the condition can only be canceled by setting the system to the stop condition or by turning the power off and on again. When wishing not to use the motor lock protection circuit, connect the CSD pin to ground.

### 11. Low voltage protection circuit

The low voltage protection circuit cuts off the bottom-side output transistors (external) when the voltage at the  $V_{REG}$  pin falls below 3.75V (typ.). The circuit action is released when the voltage rises above approx. 4.0V (typ.).

### 12. F/R switching

Forward/reverse switching in principle should be carried out while the motor is stopped. If switching is carried out while the motor is running, feedthrough current (due to output transistor delay) is prevented by the circuit design, but a high current will flow in the output transistors (due to counterelectromotive voltage and coil resistance). If such a condition is anticipated, the output transistors must be selected appropriately, to allow handling even higher current than in normal use.

### 13. Soft start

In PAM drive mode, connecting a capacitor (approx. 0.01 to 0.1  $\mu$ F) between the SOFT pin and ground enables soft start (gradual increase in PWM ON duty cycle, causing a sloped rise in motor supply voltage). This prevents the current flow exceeding the set current due to switching regulator circuit delay at startup. The Soft start function is active only immediately after motor startup.

When the motor is stopped, the output transistors are turned off, therefore the charge accumulated in the switching regulator smoothing capacitors can only be discharged as leak current of the output transistors. When the motor is restarted before the supply voltage has dropped, the soft start function will not be active. Therefore it is necessary to discharge the capacitors via a resistor so that the soft start function operates properly.

Pin Descriptions

36	CSD		Reference signal oscillator for motor lock protection circuit, clock interruption error protection circuit etc. Connect to ground via capacitor. Connect directly to ground if protection circuit is not to be used.
FRAME	GND		Ground

- Specifications of any and all SANYO products described or contained herein stipulate the performance, characteristics, and functions of the described products in the independent state, and are not guarantees of the performance, characteristics, and functions of the described products as mounted in the customer's products or equipment. To verify symptoms and states that cannot be evaluated in an independent device, the customer should always evaluate and test devices mounted in the customer's products or equipment.
- SANYO Electric Co., Ltd. strives to supply high-quality high-reliability products. However, any and all semiconductor products fail with some probability. It is possible that these probabilistic failures could give rise to accidents or events that could endanger human lives, that could give rise to smoke or fire, or that could cause damage to other property. When designing equipment, adopt safety measures so that these kinds of accidents or events cannot occur. Such measures include but are not limited to protective circuits and error prevention circuits for safe design, redundant design, and structural design.
- In the event that any or all SANYO products(including technical data, services) described or contained herein are controlled under any of applicable local export control laws and regulations, such products must not be exported without obtaining the export license from the authorities concerned in accordance with the above law.
- No part of this publication may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying and recording, or any information storage or retrieval system, or otherwise, without the prior written permission of SANYO Electric Co., Ltd.
- Any and all information described or contained herein are subject to change without notice due to product/technology improvement, etc. When designing equipment, refer to the "Delivery Specification" for the SANYO product that you intend to use.
- Information (including circuit diagrams and circuit parameters) herein is for example only ; it is not guaranteed for volume production. SANYO believes information herein is accurate and reliable, but no guarantees are made or implied regarding its use or any infringements of intellectual property rights or other rights of third parties.

This catalog provides information as of December, 1998. Specifications and information herein are subject to change without notice.
