MV1822

PDC, VPS AND TIME RECEIVER

(Supersedes version in October 1995 Media IC Handbook, HB3120 –3.0)

The MV1822 is a member of the Enhanced Video Automation (EVA) family for receiving Programme Delivery Control (PDC) messages, packet 8/30 Format 2, broadcast in World System Teletext (WST). It will automatically switch to receiving Video Programme System (VPS) data from TV line 16 in Manchester bi-phase format in the absence of PDC data. Under control of the mode pins, it can also receive Broadcast Service Data Packet format one data to provide Unified Date and Time (UDT) or Time data from headers. The data from a service can be read via the I²C bus connections in a standard format (see pages 7, 8 and 9).

FEATURES

- On-chip analog data slicing
- Low external component count
- Low frequency 6 · 9375MHz oscillator
- I²C Bus and DAV released during power down
- Automatic PDC/VPS operation
- Advanced CMOS technology gives low power dissipation and high reliability
- "Fast–Mode" I²C bus

APPLICATIONS

- Accurate programme recordings via PDC and VPS
- Automatic Date/Time setting of VCR and TV
- Automatic tuning of VCR and TV via station ident

PIN DESCRIPTION

Symbol	Pin No	Pin Name and Description	
RESET	1	Active low reset.	
MODE 1	2	Control input see truth table below for function. Includes a 75k Ω pull-down resistor	
CAPO	3	Capacitor zero, storage for reference voltage	
MODE 2	4	Control input see truth table below for function. Includes a 75k Ω pull–down resistor	
VIDEO	5	Input for composite video signal with negative going syncs	
GND	6	Ground, 0V	
TEST	7	Test pin, for factory use only, leave open circuit or connected to V _{DD}	
AS	8	Address select for I ² C bus, 0010 0001 if set high, or 0010 0011 if set low	
DATA	9	Data output	
SYNC	10	Sync output	
SCL	11	I ² C bus serial clock input	
V _{DD}	12	Positive supply voltage, +5V	
SDA	13	I ² C bus bi-directional data port	
DAV	14	Active low open drain output data available signal to microprocessor	
ХТО	15	Crystal out, 6.9375MHz fundamental crystal with on-chip 1MQ resistor to XTI	
XTI	16	Crystal input	

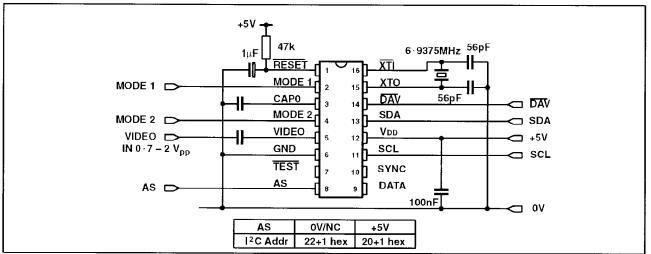

Fig. 3. Typical application diagram

MV1822
TRUTH TABLE FOR MODE 1 & 2 PINS.

MODE 2 (pin 4)	MODE 1 (pin 2)	FUNCTION
0	0	PDC or VPS
0	1	VPS only
1	0	UDT
1	1	HEADER TIME

Pins MODE 1 and MODE 2 are latched in on the leading edge of sync. When either pin changes state, the contents of the read registers are reset to all 1's and DAV is reset off.

FUNCTIONAL DESCRIPTION

The video signal is sliced to produce data and synchronising signals. Timing circuits monitor the sync signal to enable the MV1822 to lock on to the broadcast signal. A timing window, for the Vertical Blanking Interval (VBI) lines 6–22 and 318–335, is established to enable the acquisition circuit to monitor the sliced data signal for valid teletext or VPS line 16 data. In normal use both MODE 1 and MODE 2 pins are set low to receive PDC or VPS data. When UDT data is required, the MODE 1 pin must be low and the MODE 2 pin must be high. When VPS only data is required, the MODE 1 pin the MODE 2 pin low. When TIME data from the header is required, both MODE 1 and MODE 2 pins are set high. An internal pull–down resistor is provided on each mode pin so that for normal mode of operation, the pins may be left open circuit.

Byte number convention

There are 45 bytes in a teletext data packet, numbered 1 to 45. Bytes 1 and 2 are the clock run in, byte 3 is the framing code, bytes 4 and 5 are the magazine and row address group. In packet 8/30 byte 6 is used to indicate the designation code.

PDC reception

The framing code is checked for valid World System Teletext (WST) data. Magazine, packet and designation code bytes are checked and only valid Broadcast Service Data Packets (BSDP) are accepted. These are also known as packet 8/30. Format two packets, containing the PDC message, are signalled by byte six, data bit two being set high and bits 3 and 4 set low. Bytes 13 to 25 inclusive are Hamming decoded (8, 4) and stored in seven registers each of eight bits. If the complete message is correctly received with no uncorrectable Hamming errors, an interrupt to the microprocessor is signalled by the DAV pin going low. At the same time the data is transferred to a second bank of registers. provided there is no I²C bus activity at the time, reorganised with original numbered bytes 14, 15, 24, 25 and 13 placed after byte 23, to read out on the I²C bus when so requested, see page 7.

VPS reception

The VPS data consists of 15 eight bit words encoded in Manchester bi-phase format with a data rate of 2 • 5Mbits/sec. It is transmitted in only TV line 16 so similar data on other TV lines is excluded. A data low to high transition indicates a binary zero and a high to low transition indicates a binary one. Word 1 acts as a clock run in code (10/10/10/10/10/10/10/10/ to synchronise the decoder. Word 2 is a start code (10/00/10/10/10/01/10/01) to verify the required data. Note, the second element 00 contains a deliberate violation of the Manchester bi-phase format which is only permitted in word 2. Words 5, 11, 12, 13, 14 and 15 are Manchester bi-phase decoded and if verified are stored in the input registers. When all the message is correctly received, an interrupt to the microprocessor is signalled by the DAV pin going low. At the same time the data is transferred to a second bank of registers, provided there is no l^2C bus activity at the time, reorganised into the sequence – Words 11, 12, 13, 14, 5, 15, followed by 1111110, to be read out on the l^2C bus when requested, see page 7.

PDC/VPS arbitration

In normal mode with both MODE 1 and MODE 2 pins low, PDC data transmitted via Teletext packets 8/30 Format 2, will take precedence over VPS data. A 64 state frame counter is reset by every valid PDC packet, which will inhibit VPS reception until the counter reaches maximum. This will ensure that if receiving both signals on a given transmission, the PDC data will dominate, but if it does at any time cease to be received, the VPS data will be enabled within $2 \cdot 56$ seconds of the last PDC packet. This allows for one packet 8/30 format 2 to be missed without changing to VPS operation.

VPS only mode

In this mode there will be no 2.56 second delay before acquiring VPS signals.

UDT reception

When UDT is enabled, PDC and VPS reception is disabled. When packet 8/30 format one is received, the UDT data in 8 bit format, starting with byte 13, is read into the internal registers provided the I^2C bus is not busy. The received UDT data from byte 16 to byte 21 inclusive has had a one added to each data nibble, to ensure transitions exist when the time data contains many zeros. The MV1822 therefore subtracts a one from each nibble in bytes 16 to 21, so that the output will supply actual UDT data. See pages 5 and 8 for details. The data is not Hamming encoded, so when the complete packet to byte 25 has been received, an interrupt to the microcontroller is generated by the DAV pin going low.

When DAV is low, I²C bus readout inhibits reception of further UDT data. If readout is attempted before DAV goes low, FF bytes will be output and data reception will not be affected.

If readout occurs after the reception of further UDT data has begun then FF bytes will be output and data reception will not be affected. However, if DAV is already low when another packet 8/30 format one is received, then DAV will be released at byte 13, until all data has been received at byte 25, when a new interrupt to the microcontroller will be generated by the DAV pin going low again. This process will repeat until the data is read via I^2C .

Header TIME

If UDT data is not being broadcast, the time data may be obtained from the last eight bytes of the header packets. If the transmission is in serial mode, C11=1, the last eight bytes of **every** header will be received. Any byte failing parity check will not be written to the registers and the previous value in that location will be retained. As each byte is accepted, numerical data having values 30 to 39 hex (0 to 9 ASCII) will be 30 hex (0 ASCII) subtracted before being written to the registers. All other data will be written as F hex. If the transmission is in parallel mode, C11=0, the last eight bytes of only **magazine 100** headers will be received with no errors, an interrupt to the microcontroller is generated by the DAV pin going low. At the

same time the data is transferred to a second bank of registers, provided there is no I2C bus activity at the time. Details of the data output format on the I2C bus are given on page 9.

I²C bus interface

The MV1822 is configured as an I^2C bus slave transmitter with a selectable address. The I^2C bus address is 0010 0001 (20+1hex) with the address select (AS) pin set high, or 0010 0011 (22+1hex) with the AS pin set low. The read bit (LSB) must always be set, it is not possible to write to the MV1822.

On recognising its address, the MV1822 will send an acknowledge and then transmit on the SDA line the first byte from the output registers, most significant bit (MSB) first. It will then monitor the SDA line "for an acknowledge" from the microprocessor. If the microprocessor does NOT send an acknowledge, the MV1822 will release the data line to allow the microprocessor to send a stop condition. If the microprocessor does send an acknowledge, the following bytes of the message will be output provided each byte is acknowledged.

In normal mode there will be seven bytes of data available, the final data byte will be either, PDC byte 13 followed by 1111 or 11111110 for VPS messages, see page 7. The last nibble of the message serves to indicate the source of data: 1111=PDC, 1110=VPS

In UDT mode there will be 13 bytes of data available when DAV has gone low, the last byte contains the second half of the 2nd Short Programme Label, see page 8.

In header TIME mode there will be four bytes of data available when DAV has gone low, see page 9.

When readout is complete, the DAV pin is released. If the microprocessor continues to send clocks on the SCL line, the MV1822 will output FF bytes on the SDA line. Also if the

Example of UDT packet 8/30 format one data

MV1822 is re-addressed before further data is received and DAV goes low, the MV1822 will output FF bytes on the SDA line. The microprocessor can prematurely stop the message by NOT sending an Acknowledge (followed optionally by a STOP condition) after any byte has been sent by the MV1822

STOP condition) after any byte has been sent by the MV1822. The DAV pin will then be released. Also, if after a partial readout, the microprocessor sends a repeat START condition followed by the MV1822 I²C bus address, or the mode pins are changed state, DAV pin will be released and the MV1822 will output FF bytes on the SDA line.

To prevent any corruption of the data in the output registers during I²C bus activity, valid PDC or VPS messages are held in the incoming registers until I²C bus activity ceases. Here they may be over-written by new PDC or VPS messages until the I²C bus activity ceases and they can be transferred to the output registers. In the absence of I²C bus reads, subsequent valid messages will continue to be transferred to the output registers over-writing any existing data. In this way the output registers always contain the latest PDC or VPS message, see page 7.

When DAV goes low I²C bus readout inhibits reception of further UDT data. If readout is attempted before DAV goes low, FF bytes will be output and data reception will not be affected.

General information

System clock is provided by an on chip 6.9375MHz oscillator together with an external parallel resonant fundamental frequency AT cut crystal.

Following a reset (RESET pulled low), the DAV pin will be released. When the MV1822 is powered down, the I^2C bus and DAV pins will be released so that the lines can be used by other devices.

		vork ent	LTO			ified Julian Co–ordinated ate (MJD) Universal Time (UTC)		SPL 1		SPL 2			
Byte number	13	14	15	16	17	18	19	20	21	22	23	24	25
Data received	5F	F6	85	F5	99	52	25	23	54	54	45	D3	54
I ² C bus Data out	5F	F6	85	E4	88	41	14	12	43	54	45	D3	54

Notes: The I²C bus data in bytes 16 to 21 has had a one subtracted from each nibble to obtain actual data. The example decodes to BBC 1, 7 August 1992, 15 hours, 12 minutes, 43 seconds British Summer Time or 14:12:43 Greenwhich Mean Time. The Local Time Offset (LTO) is + 1 hour. SPL 1 & 2 decode as "TEST" when parity is removed.

Table 3. Modified Julian Date for various calendar dates

The day number is found from the equation MJD mod (7), i.e. divide by 7 and keep the integer remainder.

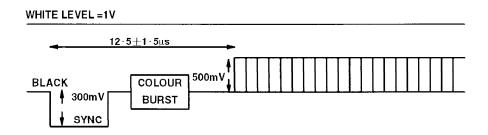

MV1822

MV1822 Video waveform of packet 8/30/2 (PDC)

For a $1V_{pp}$ signal, as shown, the data is $462mV_{pp} = 66\%$ of picture. Time is measured from the negative sync edge to the peak of the seventh clock run-in pulse.

Video waveform of data line 16 (VPS)

For a $1V_{pp}$ video signal, as shown, the data is $500mV_{pp}$, modulation depth 71 · 4%. Time is measured from the negative sync edge to the start of data.

	bit 0		bit 0	

Order of header TIME data output on the I²C bus

NOTE: Data is output on the I²C bus \underline{MSB} first

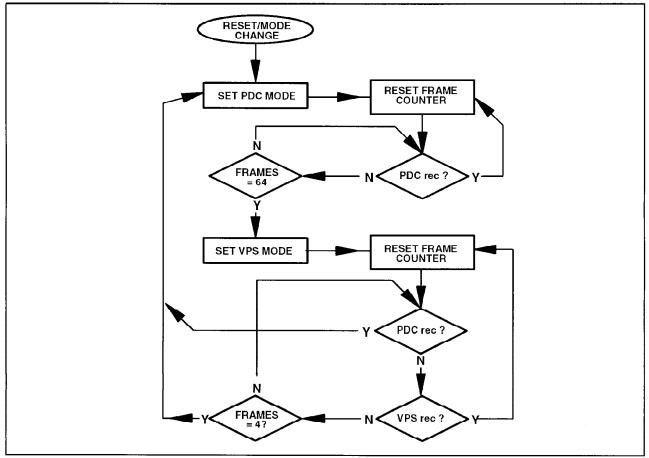

Fig. 4 Normal mode PDC/VPS switching

* The operation of the MV1822, in the presence of both Line 16 (VPS) and packet 8/30/2, follows the guide lines of the EBU Code Of Practice, SPB 459 Revision 2, February 1992, page 49:

"-when both Line 16 (VPS) and teletext delivered labels are available simultaneously, decoders should default to the teletext delivered service." The counter is incremented once/frame.

One line =64µs One frame = 625 lines

PDC timeout count = 64 frames = $625 \times 64 \mu s \times 64 = 2 \cdot 65s$ VPS timeout count = 4 frames = $625 \times 64 \mu s \times 4 = 160 ms$

VPS only mode

The flow diagram above is not relevant.
