T7504 and T5504 Quad PCM Codecs with Filters

Features

- 5 V only
- Low-power, latch-up-free CMOS technology
  — 37 mW/channel typical operating power dissipation
  — 1 mW/channel typical powerdown dissipation
- Automatic master clock frequency selection
  — 2.048 MHz or 4.096 MHz
- On-chip sample and hold, autozero, and precision voltage reference
- Differential architecture for high noise immunity and power supply rejection
- Flexible time-slotted PCM interface
  — 2.048 MHz or 4.096 MHz data rate
- Meets or exceeds ITU-T G.711—G.712 requirements and VF characteristics of D3/D4 (as per Agere Systems Inc.'s PUB43801)
- Operating temperature range: –40 °C to +85 °C
- µ-law/A-law companding selectable

Description

The T7504 and T5504 devices are single-chip, four-channel µ-law/A-law PCM codecs with filters. These integrated circuits provide analog-to-digital and digital-to-analog conversion. They provide the transmit and receive filtering necessary to interface a voice telephone circuit to a time-division multiplexed system. These devices are available in 28-pin PLCCs. The T7504 is also available in a 44-pin MQFP.

The T5504 differs from the T7504 in its timing mode. The T5504 operates in the nondelay timing mode (digital data valid when frame sync goes high), and the T7504 operates in the delayed timing mode (digital data is valid one clock cycle after frame sync goes high) (see Figures 6—9).

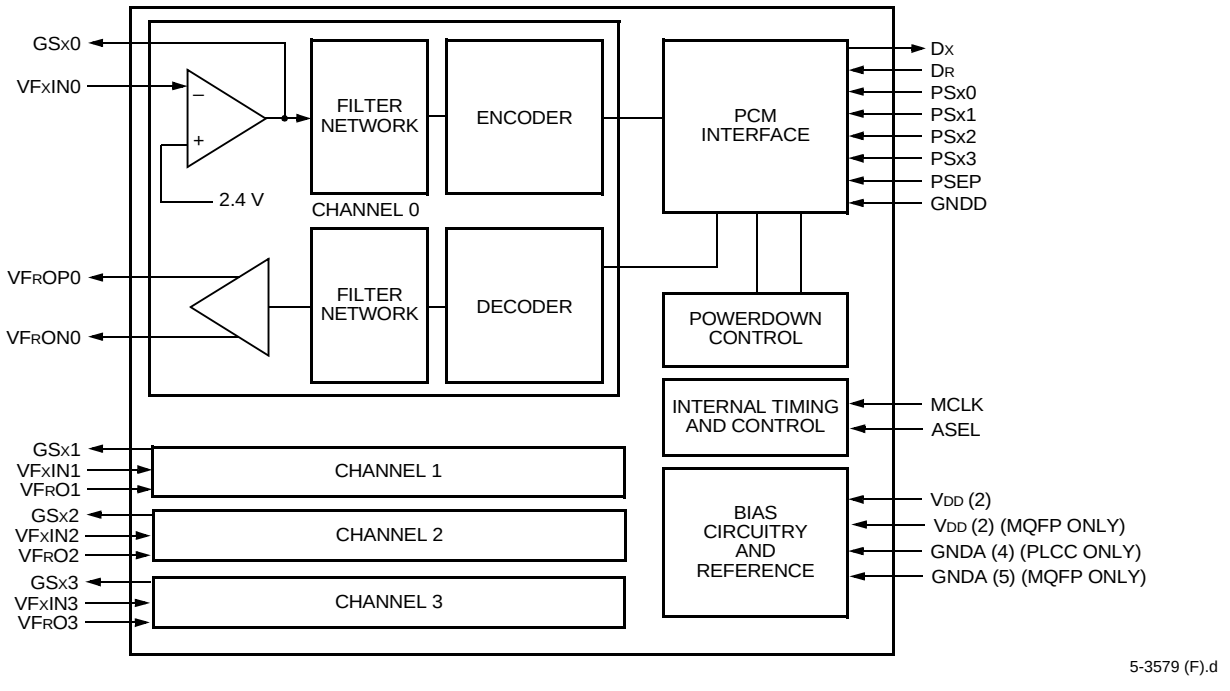

Figure 1. Block Diagram For 28-Pin DIP and 28-Pin PLCC

Functional Description

Four channels of PCM data input and output are passed through only two ports, DX and DR, so some type of time-slot assignment is necessary. The scheme used here is to utilize timing modes of 32 or 64 time slots corresponding to master clock frequencies of either 2.048 MHz or 4.096 MHz, respectively. Each device has four transmit frame sync (FSX) inputs, one for each channel. During a single 125 µs frame, each transmit frame sync input is supplied a single pulse. The timing of the pulse indicates the beginning of the time slot during which the data for that channel is clocked out of the device. During a frame, transmit frame sync pulses must be separated from each other by one or more time slots. A channel is placed in a standby (low-power) mode if its FSX input has been low for 500 µs.

There is a single frame sync separation input (FSEP). The number of negative clock edges minus one that occurs while FSEP is high is the delay (in clock periods) that is placed between the rising edge of a transmit frame sign bit and the falling edge used by the receiver to sample the sign bit. There must always be a pulse on the FSEP input since this input provides the 8 kHz signal required to maintain internal timing. If the FSEP pulse is one clock period or less, the device makes the transmit edges and receive sampling edges one half clock period apart. The entire device is placed in a powerdown mode if FSEP remains low for 500 µs.

Time slot zero is defined as starting on the first rising MCLK edge after FSEP = 1 is detected by a negative MCLK edge. In the T7504, MCLK negative-going edges that detect the start of FSEP and FSXN must be integer multiples of eight MCLK periods apart (zero multiples are allowed). Since FSEP is assumed to define time slot 0, the number of multiples separating FSXN and FSEP is the time-slot number. In the T5504, FSXN for time slot 0 nominally starts on the MCLK positive edge following the negative edge which detects FSEP.

The frequency of the master clock must be either 2.048 MHz or 4.096 MHz. Internal circuitry determines the master clock frequency during the powerup reset interval.

Powerdown is not guaranteed if MCLK is lost unless the device is already in the powerdown mode due to FSEP low for at least 500 µs.

The analog input section in Figure 2 includes an on-chip op amp that is used in conjunction with external, user-supplied resistors to vary encoder passband gain. The feedback resistance (RF) should range from 10 kΩ to 200 kΩ and capacitance from GSx to ground should be kept to less than 50 pF. The input signal at VFXIN should be ac coupled. For best performance, the maximum gain of this op amp should be limited to 20 dB or less.

Pin Information (continued)

Table 1. Pin Descriptions

Symbol	Pin		Type*	Name/Function
	PLCC	MQFP		
VFXIN3 VFXIN2 VFXIN1 VFXIN0	14 8 16 22	15 8 19 26	I	**Voice Frequency Transmitter Input.** Analog inverting input to the uncommitted operational amplifier at the transmit filter input. Connect the signal to be digitized to this pin through a resistor RI (see Figure 2).
GSX3 GSX2 GSX1 GSX0	13 9 17 21	14 9 20 25	O	**Gain Set for Transmitter.** Output of the transmit uncommitted operational amplifier. The pin is the input to the transmit differential filters. Connect the pin to its corresponding VFXIN through a resistor RF (see Figure 2).
VFRO3 VFRO2 VFRO1 VFRO0	12 10 18 20	13 10 21 24	O	**Voice Frequency Receiver Output.** This pin can drive 2000 Ω (or greater) loads.
VDD [1:0] VDDA [1:0]	7, 24 —	3, 31 4, 30	—	**5 V Digital and Analog Power Supplies**. All pins must be connected on the circuit board. Each pin should be bypassed to ground with at least 0.1 µF of capacitance as close to the device as possible. For the DIP and PLCC packages, VDD serves both analog and digital internal circuits.
GNDA4 GNDA3 GNDA2 GNDA1 GNDA0	— 15 11 19 23	18 16 11 23 27	—	**Analog Grounds**. All ground pins must be connected on the circuit board.
DR	4	44	I	**Receive PCM Data Input**. The data on this pin is shifted into the device on the falling edges of MCLK. Data is only entered for valid time slots as defined by the relationship of the pulses on the FSX inputs and the pulse on the FSEP input.
DX	3	43	O	**Transmit PCM Data Output**. This pin remains in the high-impedance state except during active transmit time slots. An active transmit time slot is defined as one in which a pulse is present on one of the FSx inputs. Data is shifted out on the rising edge of MCLK.
MCLK	5	1	I	**Master Clock Input**. The frequency must be 2.048 MHz or 4.096 MHz. This clock serves as the bit clock for all PCM data transfer. A 40% to 60% duty cycle is required.
GNDD	2	41	—	**Digital Ground**. Ground connection for the digital circuitry. All ground pins must be connected on the circuit board.
FSX3 FSX2 FSX1 FSX0	28 27 26 25	36 35 34 33	I^d	**Transmit Frame Sync**. This signal is an edge trigger and must be high for a minimum of one MCLK cycle. This signal must be derived from MCLK. The division ratio is 1:256 or 1:512 (FSX:MCLK). Each FSX input must have a pulse present at the start of the desired active output time slot. Pulses on the various FSX inputs must be separated by one or more integer multiples of time slots. An internal pull-down device is included on each FSX.
ASEL	6	2	I^d	**A-Law/µ-Law Select**. A logic low selects µ-law coding. A logic high selects A-law coding. A pull-down device is included.
FSEP	1	37	I	**Frame Sync Separation**. The pulse width of this 8 kHz signal defines the timing offset between the transmit and receive frames. Internally generated receive frame sync pulses are delayed from the corresponding transmit frame sync pulse rising edge by one less than the FSEP pulse width in negative MCLK edges. If the pulse width is one MCLK period or less, the transmit and receive frame syncs are made coincident. Loss of FSEP causes the device to powerdown. If the master clock frequency is 2.048 MHz or 4.096 MHz, delays of 255 or 511 clock pulses are not allowed, respectively. Timing relationships between FSEP, FSXN, and time slot 0 are given in Figures 6—9.

* I^d Indicates a pull-down device is included on this lead.

Absolute Maximum Ratings

Stresses in excess of the absolute maximum ratings can cause permanent damage to the device. These are absolute stress ratings only. Functional operation of the device is not implied at these or any other conditions in excess of those given in the operational sections of this data sheet. Exposure to absolute maximum ratings for extended periods can adversely affect device reliability.

Parameter	Symbol	Min	Max	Unit
Storage Temperature Range	T_{stg}	–55	150	°C
Power Supply Voltage	V_{DD}	—	6.5	V
Voltage on Any Pin with Respect to Ground	—	–0.5	0.5 + V_{DD}	V
Maximum Power Dissipation (package limit)	P_D	—	600	mW

Handling Precautions

Although protection circuitry has been designed into this device, proper precautions should be taken to avoid exposure to electrostatic discharge (ESD) during handling and mounting. Agere employs a human-body model (HBM) and a charged-device model (CDM) for ESD susceptibility testing and protection design evaluation. ESD voltage thresholds are dependent on the circuit parameters used to define the model. No industry-wide standard has been adopted for CDM. However, a standard HBM (resistance = 1500 Ω, capacitance = 100 pF) is widely used and, therefore, can be used for comparison purposes. The HBM ESD threshold presented here was obtained by using these circuit parameters:

HBM ESD Threshold Voltage	
Device	**Rating**
T7504	>2000 V
T5504	>2000 V

Electrical Characteristics

Specifications apply for T_A = –40 °C to +85 °C, V_{DD} = 5 V ± 5%, MCLK = either 2.048 MHz or 4.096 MHz, and GND = 0 V, unless otherwise noted.

ac Transmission Characteristics

Unless otherwise noted, the analog input is a 0 dBm0, 1020 Hz sine wave; the input amplifier is set for unity gain. The digital input is a PCM bit stream equivalent to that obtained by passing a 0 dBm0, 1020 Hz sine wave through an ideal encoder. The output level is sin(x)/x-corrected.

Table 12. Interchannel Crosstalk (Between Channels) $R_F = \leq 200\ k\Omega$ (See note below.)

Parameter	Symbol	Test Conditions	Min	Typ	Max	Unit
Transmit to Receive Crosstalk 0 dBm0 Transmit Levels	CT_{XX-RY}	f = 300 Hz—3400 Hz idle PCM code for channel under test; 0 dBm0 into any other single channel VF_XIN	—	–95	–75	dB
Receive to Transmit Crosstalk 0 dBm0 Receive Levels	CT_{RX-XY}	f = 300 Hz—3400 Hz VF_XIN = 0 Vrms for channel under test; 0 dBm0 code level on any other single channel D_R	—	–92	–75	dB
Transmit to Transmit Crosstalk 0 dBm0 Transmit Levels	CT_{XX-XY}	f = 300 Hz—3400 Hz 0 dBm0 applied to any single channel VF_XIN except channel under test, which has VF_XIN = 0 Vrms	—	–90	–75	dB
Receive to Receive Crosstalk 0 dBm0 Receive Levels	CT_{RX-RY}	f = 300 Hz—3400 Hz 0 dBm0 code level on any single channel D_R except channel under test, which has idle code applied	—	–95	–75	dB

Table 13. Intrachannel Crosstalk (Within Channels) $R_F = \leq 200\ k\Omega$ (See Note below.)

Parameter	Symbol	Test Conditions	Min	Typ	Max	Unit
Transmit to Receive Crosstalk 0 dBm0 Transmit Levels	CT_{XX-RX}	f = 300 Hz—3400 Hz idle PCM code for channel under test; 0 dBm0 into VF_XIN	—	–95	–65	dB
Receive to Transmit Crosstalk 0 dBm0 Receive Levels	CT_{RX-XX}	f = 300 Hz—3400 Hz VF_XIN = 0 Vrms for channel under test; 0 dBm0 code level on D_R	—	–73	–65	dB

Note: For Tables 11 and 12, crosstalk into the transmit channels (VF_XIN) can be significantly affected by parasitic capacitive feeds from GS_X and VF_RO outputs. PWB layouts should be arranged to keep these parasitics low. The resistor value of R_F (from GS_X to VF_XIN) should also be kept as low as possible (while maintaining the load on GS_X above 10 kΩ per Table 4) to minimize crosstalk.
