

CMOS 4-BIT MICROCONTROLLER

**TMP47P440VN
TMP47P440VF**

The 47P440V is the system evaluation LSI of 47C440B with 32K bits one-time PROM. The 47P440V programs / verifies using an adapter socket to connect with PROM programmer, as it is in TMM2764AD.

In addition, the 47P440V and the 47C440B are pin compatible. The 47P440V operates as the same as the 47C440B by programming to the internal PROM.

OPERATIONAL DESCRIPTION

The following is an explanation of hardware configuration and operation in relation to the 47P440V. The 47P440V is the same as the 47C440B except that an OTP is used instead of a built-in mask ROM.

1. OPERATION mode

The 47P440V has an MCU mode and a PROM mode.

1.1 MCU mode

The MCU mode is set by fixing the TEST/VPP pin at the "L" level. Operation in the MCU mode is the same as for the 47C440B, except that the TEST/VPP pin does not have built in pull-down resistor and cannot be used open.

1.1.1 Program Memory

The program storage area is the same as for the 47C440B.

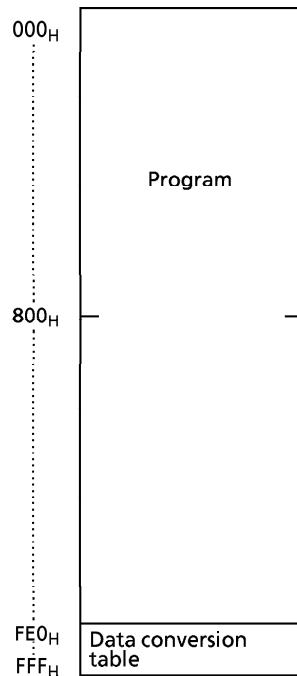

Figure 1-1. Program area

1.1.2 Data Memory

The 47P440V has 256×4 -bit data memory (RAM).

1.1.3 Input/Output Circuitry

(1) Control pins

This is the same as for the 47C440B except that there is no built-in pull-down resistance for the TEST pin.

(2) I/O Ports

The input/output circuit of the 47P440V is the same as I/O code SA of the 47C440B.

External resistance, for example, is required when using as evaluator of other I/O codes (SB, SC), (Refer to Figure 1.2)

Figure 1-2. I/O code and external circuitry

1.2 PROM mode

The PROM mode is set by setting the **RESET** and **HOLD** pins to the "L" level. The PROM mode can be used as a general-purpose PROM writer for program writing and verification. (A high-speed program mode is used set the ROM type the same as for the TMM 2764D and an end address of FFFF_H).

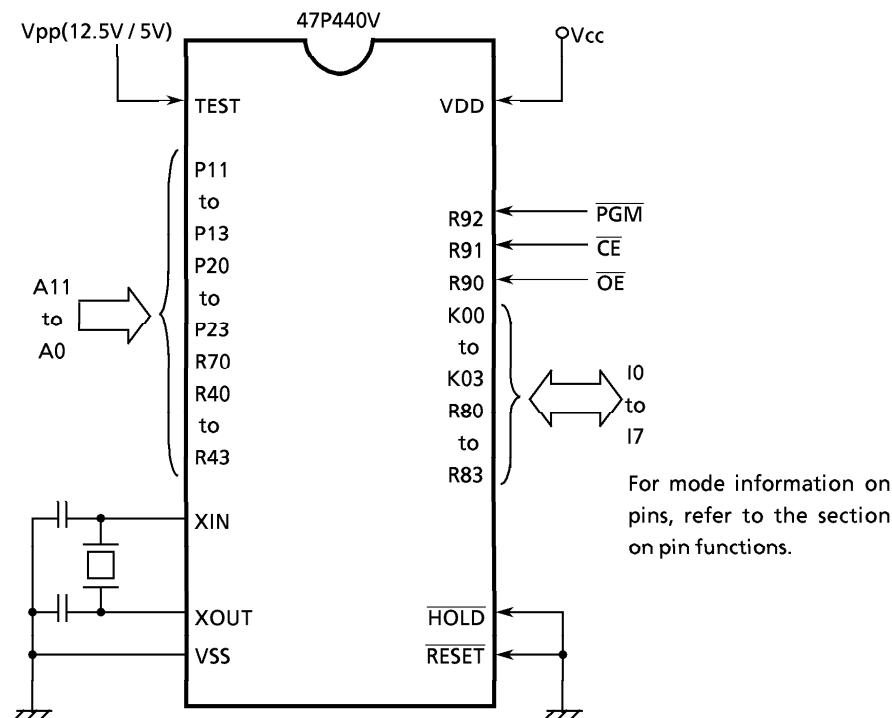

Figure 1-3. Setting for PROM mode

When writing a program, set a ROM type to "TMM2764AD" (programming voltage : 12.5V).

Since the 47P440V has 4096 × 8 bit internal PROM (000 to FFFH), set a stop address of a PROM writer to "FFFH", or store the same data of "FFH" to the latter half addresses 1000 to 1FFFH.

1.2.1 High Speed Programming Mode

The device is set up in the high speed programming mode when the programming voltage (12.5V) is applied to the V_{pp} pin with V_{cc} = 6V and PGM = V_{IH4}. The programming is achieved by applying a single TTL low level 1 msec, pulse the PGM input after addresses and data are stable. Then the programmed data is verified by using Program Verify mode. If the programmed data is not correct, another program pulse of 1 msec is applied and then programmed data is verified. This should be repeated until the program operates correctly (max. 25 times). After correctly programming the selected address, one additional program pulse with pulse width 3 times that needed for programming is applied. When programming has been completed, the data in all addresses should be verified with V_{cc} = V_{pp} = 5V.
