# Tri-EL Lamp Driver IC 

## Features

- Tri-EL lamp driver with common terminal
- Independent brightness control for all 3 lamps
- 1.8 V to 6.5 V Operating Supply Voltage
] Output voltage regulation
- Two-pin serial data communication for control
- Linear brightness control with seven steps at constant efficiency
- 128 kHz Fixed Switching Frequency
- Split supply capability
- Patented high efficiency EL lamp driver
- Single miniature inductor drives all 3 lamps
- Only 4 external components
- Burst mode power converter for best efficiency
- CMOS compatible serial interface with noise rejection
- 150nA max. leakage current when disabled
- Power-on reset causes all outputs to be off when first powered up
- Small 10-pin MSOP package
- 10-pin DFN/MLP package ( 0.8 mm thickness)

## Applications

- Mulit-segment, variable displays
- Cell phone keypads and displays
- MP3 players
- Watches

## General Description

The Supertex HV858 is a high voltage triple EL lamp driver designed for driving combined EL lamps of up to $3.0 \mathrm{in}^{2}$ ( $1.0 \mathrm{in}^{2}$ each). The input supply voltage range is from 1.8 V to 6.5 V . The device is designed such that the input voltage to the inductor can be different from the input voltage to the device (split supply). The device uses a single inductor and a minimum number of passive components. The nominal regulated output voltage that is applied to the EL lamp is $\pm 95 \mathrm{~V}$. The HV858 has two internal oscillators, one for the internal switching MOSFET, and the other for the high voltage EL lamp driver. The EL lamp frequency is fixed internally at 500 Hz . The power converter oscillator runs 256 times faster than the EL lamp driver at 128 kHz .
An external inductor is connected between the $L_{x}$ and $V_{p D}$ pins (or between the $L_{x}$ pin and separate voltage source in the case of a split supply application). A $0.002-0.01 \mu \mathrm{~F}, 100 \mathrm{~V}$ capacitor is connected between the $\mathrm{C}_{\mathrm{s}}$ pin and ground. The switching MOSFET charges the external inductor and discharges it into the capacitor at the $\mathrm{C}_{\mathrm{s}} \mathrm{pin}$. The voltage at $\mathrm{C}_{\mathrm{s}}$ will start to increase. Once the voltage at $\mathrm{C}_{\mathrm{s}}$ reaches a nominal value of 95 V , the switching MOSFET is turned OFF to conserve power.
One side of the 3 EL lamps is connected to the Com pin of HV858 and the other side to the EL1, EL2, and EL3 pins of the HV858. Each EL lamp output may be independently controlled to have one of the 7 brightness levels or can be completely turned OFF by a 10 -bit serial data input register. The 10 -bit control code has 3 bits to control the brightness level of each EL Lamp and one bit to optionally control the power converter. The 3-bit binary brightness control code controls the number of 500 Hz cycles (from 0 to 7 ) in a group of 7 cycles.

## Typical Application Circuit

Pin Configuration

| Pin | Name | Description |
| :---: | :---: | :--- |
| 1 | $\mathrm{~L}_{\mathrm{X}}$ | Inductor pin |
| 2 | GND | Ground pin |
| 3 | V $_{\text {DD }}$ | Input voltage supply pin. It is common practice to use a bypass <br> capacitor as close as possible to the device on this pin. |
| 4 | SDI | Serial data input pin |
| 5 | SCK | Serial clock input pin |
| 6 | EL1 | EL lamp 1 pin |
| 7 | EL2 | EL lamp 2 pin |
| 8 | EL3 | EL lamp 3 pin |
| 9 | COM | Common pin for one side of all 3 EL lamps |
| 10 | C $_{S}$ | High Voltage capacitor pin |

## Logic Input Conditions

The serial data input consists of a 10-bit string, 3-bits of brightness control and one bit(10 th bit) to optionally control the power converter. The power converter runs if any of the EL lamps has a non-zero brightness value or if the PWR_ON bit is high while the other 9 bits are low.

1. SDI may be H or L if SCK is H .
2. SCK may be H or L if SDI is H .
3. While inputting serial data to the shift register, SDI can change value only when SCK is $L$.
4. The previous 10 bits of serial input will be latched when SDI makes L to H transition while SCK is H .

## EL Lamp Brightness Control

The EL Lamp brightness control is a 3-bit binary number stored in a latch, which is provided by a serial to parallel conversion shift register.

1. If all the 3 bits for a designated EL lamp are $L$, the differential voltage across that lamp will be zero.
2. If any of the 3 bits for a designated EL lamp is H :
a. The 3-bit value sets the average number of cycles for which the EL lamp voltage is non-zero.
b. The EL lamp brightness is linearly proportional to the binary lamp control code.

Functional Block Diagram

Note: This drawing is a generalized representation. Actual internal circuitry may differ.

## Differential Output Waveform

The following is the differential output waveform across the lamp for each 3-bit input code for each lamp.

Figure 1 : Test Circuit

*Any 100V fast reverse recovery diode can be used
Note: Maximum lamp size for each segment is $1.0 \mathrm{in}^{2}$. To drive larger size lamps, any combination of EL1, EL2 and EL3 can be paralleled. However, the 3-bit serial data input code (for each output) should be such that the paralleled outputs have the same code.

Typical Performance $\left(v_{D O}=v_{N}=3.0 \mathrm{~V}\right)$
