

### <1mV Voltage Offset, 600MHz Amplifiers

The EL5156, EL5157, EL5256, and EL5257 are 600MHz bandwidth -3dB voltage mode feedback amplifiers with

DC accuracy of <0.01%, 1mV offsets and 40kV/V open loop gains. These amplifiers are ideally suited for applications ranging from precision measurement instrumentation to high speed video and monitor applications demanding the very highest linearity at very high frequency. Capable of operating with as little as 6.0mA of current from a single supply ranging from 5V to 12V and dual supplies ranging from  $\pm 2.5V$  to  $\pm 5.0V$  these amplifiers are also well suited for handheld, portable and battery-powered equipment. With their capability to output as much as 140mA, member of this family is comfortable with demanding load conditions.

Single amplifiers are available in SOT-23 packages and duals in a 10-pin MSOP package for applications where board space is critical. Additionally, singles and duals are available in the industry-standard 8-pin SO package. All parts operate over the industrial temperature range of  $-40^{\circ}C$  to  $+85^{\circ}C$ .

### Ordering Information

### Features

- 600MHz -3dB bandwidth, 240MHz 0.1dB bandwidth
- 700V/ $\mu s$  slew rate
- <1mV input offset
- Very high open loop gains 92dB
- Low supply current = 6mA
- 140mA output current
- Single supplies from 5V to 12V
- Dual supplies from  $\pm 2.5V$  to  $\pm 5V$
- Fast disable on the EL5156 and EL5256
- Low cost

### Applications

- Imaging
- Instrumentation
- Video
- Communications devices

## **Product Description**

The EL5156, EL5157, EL5256, and EL5257 are wide bandwidth, single or dual supply, low power and low offset voltage feedback operational amplifiers. Both amplifiers are internally compensated for closed loop gain of +1 or greater. Connected in voltage follower mode and driving a 500 $\Omega$  load, the -3dB bandwidth is about 610MHz. Driving a 150 $\Omega$  load and a gain of 2, the bandwidth is about 180MHz while maintaining a 600V/ $\mu$ s slew rate. The EL5156 and EL5256 are available with a power down pin to reduce power to 17 $\mu$ A typically while the amplifier is disabled.

## **Input, Output and Supply Voltage Range**

The EL5156 and EL5157 families have been designed to operate with supply voltage from 5V to 12V. That means for single supply application, the supply voltage is from 5V to 12V. For split supplies application, the supply voltage is from  $\pm 2.5V$  to  $\pm 5V$ . The amplifiers have an input common mode voltage range from 1.5V above the negative supply ( $V_{S-}$  pin) to 1.5V below the positive supply ( $V_{S+}$  pin). If the input signal is outside the above specified range, it will cause the output signal distorted.

The outputs of the EL5156 and EL5157 families can swing from -4V to 4V for  $V_S = \pm 5V$ . As the load resistance becomes lower, the output swing is lower. If the load resistor is 500 $\Omega$ , the output swing is about -4V at a 4V supply. If the load resistor is 150 $\Omega$ , the output swing is from -3.5V to 3.5V.

## **Choice of Feedback Resistor and Gain Bandwidth Product**

For applications that require a gain of +1, no feedback resistor is required. Just short the output pin to the inverting input pin. For gains greater than +1, the feedback resistor forms a pole with the parasitic capacitance at the inverting input. As this pole becomes smaller, the amplifier's phase margin is reduced. This causes ringing in the time domain and peaking in the frequency domain. Therefore,  $R_F$  can't be very big for optimum performance. If a large value of  $R_F$  must be used, a small capacitor in the few Pico farad range in parallel with  $R_F$  can help to reduce the ringing and peaking at the expense of reducing the bandwidth.

For gain of +1,  $R_F = 0$  is optimum. For the gains other than +1, optimum response is obtained with  $R_F$  between 500 $\Omega$  to 750 $\Omega$ .

The EL5156 and EL5157 families have a gain bandwidth product of 210MHz. For gains  $> 5$ , its bandwidth can be predicted by the following equation:  $(\text{Gain}) \times (\text{BW}) = 210\text{MHz}$ .

## **Video Performance**

For good video performance, an amplifier is required to maintain the same output impedance and the same frequency response as DC levels are changed at the output. This is especially difficult when driving a standard video load of 150 $\Omega$ , because of the change in output current with DC level. The dG and dP for these families are about 0.006%

and 0.04%, while driving 150 $\Omega$  at a gain of 2. Driving high impedance loads would give a similar or better dG and dP performance.

## **Driving Capacitive Loads and Cables**

The EL5156 and EL5157 families can drive 27pF loads in parallel with 500 $\Omega$  with less than 5dB of peaking at gain of +1. If less peaking is desired in applications, a small series resistor (usually between 5 $\Omega$  to 50 $\Omega$ ) can be placed in series with the output to eliminate most peaking. However, this will reduce the gain slightly. If the gain setting is greater than 1, the gain resistor  $R_G$  can then be chosen to make up for any gain loss which may be created by the additional series resistor at the output.

When used as a cable driver, double termination is always recommended for reflection-free performance. For those applications, a back-termination series resistor at the amplifier's output will isolate the amplifier from the cable and allow extensive capacitive drive. However, other applications may have high capacitive loads without a back-termination resistor. Again, a small series resistor at the output can help to reduce peaking.

## **Disable/Power-Down**

The EL5156 and EL5256 can be disabled and their output placed in a high impedance state. The turn off time is about 330ns and the turn on time is about 130ns. When disabled, the amplifier's supply current is reduced to 17 $\mu$ A typically, thereby effectively eliminating the power consumption. The amplifier's power down can be controlled by standard TTL or CMOS signal levels at the ENABLE pin. The applied logic signal is relative to  $V_{S-}$  pin. Letting the ENABLE pin float or applying a signal that is less than 0.8V above  $V_{S-}$  will enable the amplifier. The amplifier will be disabled when the signal at ENABLE pin is above  $V_{S+} - 1.5V$ .

## **Output Drive Capability**

The EL5156 and EL5157 families do not have internal short circuit protection circuitry. They have a typical short circuit current of 95mA and 70mA. If the output is shorted indefinitely, the power dissipation could easily overheat the die or the current could eventually compromise metal integrity. Maximum reliability is maintained if the output current never exceeds  $\pm 40\text{mA}$ . This limit is set by the design of the internal metal interconnect. Note that in transient applications, the part is robust.

## **Power Dissipation**

With the high output drive capability of the EL5156 and EL5157 families, it is possible to exceed the 125 $^{\circ}\text{C}$  absolute maximum junction temperature under certain load current conditions. Therefore, it is important to calculate the maximum junction temperature for the application to determine if the load conditions or package types need to be modified for the amplifier to remain in the safe operating area.

The maximum power dissipation allowed in a package is determined according to:

$$PD_{MAX} = \frac{T_{JMAX} - T_{AMAX}}{\theta_{JA}}$$

Where:

$T_{JMAX}$  = Maximum junction temperature

$T_{AMAX}$  = Maximum ambient temperature

$\theta_{JA}$  = Thermal resistance of the package

The maximum power dissipation actually produced by an IC is the total quiescent supply current times the total power supply voltage, plus the power in the IC due to the load, or:

For sourcing:

$$PD_{MAX} = V_S \times I_{SMAX} + \sum_{i=1}^n (V_S - V_{OUTi}) \times \frac{V_{OUTi}}{R_{Li}}$$

For sinking:

$$PD_{MAX} = V_S \times I_{SMAX} + \sum_{i=1}^n (V_{OUTi} - V_S) \times I_{LOADi}$$

Where:

$V_S$  = Supply voltage

$I_{SMAX}$  = Maximum quiescent supply current

$V_{OUT}$  = Maximum output voltage of the application

$R_{LOAD}$  = Load resistance tied to ground

$I_{LOAD}$  = Load current

$N$  = number of amplifiers (Max = 2)

By setting the two  $PD_{MAX}$  equations equal to each other, we can solve the output current and  $R_{LOAD}$  to avoid the device overheat.

### Power Supply Bypassing and Printed Circuit Board Layout

As with any high frequency device, a good printed circuit board layout is necessary for optimum performance. Lead lengths should be as short as possible. The power supply pin must be well bypassed to reduce the risk of oscillation. For normal single supply operation, where the  $V_{S-}$  pin is connected to the ground plane, a single 4.7 $\mu$ F tantalum capacitor in parallel with a 0.1 $\mu$ F ceramic capacitor from  $V_{S+}$  to GND will suffice. This same capacitor combination should be placed at each supply pin to ground if split supplies are to be used. In this case, the  $V_{S-}$  pin becomes the negative supply rail.

For good AC performance, parasitic capacitance should be kept to minimum. Use of wire wound resistors should be avoided because of their additional series inductance. Use of sockets should also be avoided if possible. Sockets add parasitic inductance and capacitance that can result in compromised performance. Minimizing parasitic capacitance at the amplifier's inverting input pin is very important. The feedback resistor should be placed very close to the inverting input pin. Strip line design techniques are recommended for the signal traces.
