

### FEATURES

- Memory maps into any standard byte-wide data bus.
- Eliminates CPU “bit-banging” by internally generating all 1-Wire™ timing and control signals.
- Generates interrupts to provide for more efficient programming.
- Search ROM Accelerator relieves CPU from any single bit operations on the 1-Wire™ Bus.
- Capable of running off any system clock from 3.2MHz to 128MHz.
- Small size: all digital design, only 7700 transistors.
- Available in both Verilog and VHDL.
- Applications include any circuit containing a 1-Wire™ communication bus.

### DESCRIPTION

As more 1-Wire devices become available, more and more users have to deal with the demands of generating 1-Wire signals to communicate to them. This usually requires “bit-banging” a port pin on a microprocessor, and having the microprocessor perform the timing functions required for the 1-Wire protocol. While 1-Wire transmission can be interrupted mid-byte, it cannot be interrupted during the “low” time of a bit time slot; this means that a CPU will be idled for up to 60 microseconds for each bit sent and at least 480 microseconds when generating a 1-Wire reset. The 1-Wire Master helps users handle communication to 1-Wire devices in their system without tying up valuable CPU cycles. Integrated into a user’s ASIC as a 1-Wire port, the core is available in both VHDL and Verilog code and uses very little chip area (7700 transistors plus 1 bond pad for the Verilog version).

This circuit is designed to be memory mapped into the user’s system and provides complete control of the 1-Wire bus through 8 bit commands. The host CPU loads commands, reads and writes data, and sets interrupt control through five individual registers. All of the timing and control of the 1-Wire bus are generated within. The host merely needs to load a command or data and then may go on about its business. When bus activity has generated a response that the CPU needs to receive, the 1-Wire Master sets a status bit and, if enabled, generates an interrupt to the CPU. In addition to write and read simplification, the 1-Wire Master also provides a Search ROM Accelerator function relieving the CPU from having to perform any single-bit operations on the 1-Wire bus.

The operation of the 1-Wire bus is described in detail in the **Book of iButton Standards** [1]; therefore, the details of that will not be discussed in this document. Each slave device, in general, has its own set of commands that are described in detail in that device’s data sheet. The user is referred to those documents for detail on specific slave implementations.

## BLOCK DIAGRAM

## PIN DESCRIPTIONS

The following describes the function of all the block I/O pins. In the following descriptions, 0 represents logic low and 1 represents logic high.

**A0, A1, A2**, Register Select: Address signals connected to these three inputs select a register for the CPU to read from or write to during data transfer. A table of registers and their addresses is shown below.

### Register Addresses

| A2 | A1 | A0 | Register                                       |
|----|----|----|------------------------------------------------|
| 0  | 0  | 0  | Command Register (read/write)                  |
| 0  | 0  | 1  | Transmit Buffer (write), Receive Buffer (read) |
| 0  | 1  | 0  | Interrupt Register (read)                      |
| 0  | 1  | 1  | Interrupt Enable Register (read/write)         |
| 1  | 0  | 0  | Clock Divisor Register (read/write)            |

**$\overline{\text{ADS}}$** , Address Strobe: The positive edge of an active Address Strobe ( $\overline{\text{ADS}}$ ) signal latches the Register Select (A0, A1, A2) into an internal latch. Provided that setup and hold timings are observed,  $\overline{\text{ADS}}$  may be tied low making the latch transparent.

**CLK**, Clock Input: This is a (preferably) 50% duty cycle clock that can range from 3.2MHz to 128MHz. This clock provides the timing for the 1-Wire bus.

**D7-D0**, Data Bus: This bus comprises eight input/output lines. The bus provides bi-directional communications between the 1-Wire master and the CPU. Data, control words, and status information are transferred via this D7-D0 Data Bus.

**DQ**, 1-Wire Data Line: This open-drain line is the 1-Wire bi-directional data bus. 1-Wire slave devices are connected to this pin. This pin must be pulled high by an external resistor, nominally 5Kohms.

**$\overline{\text{EN}}$** , Enable: When  $\overline{\text{EN}}$  is low, the 1-Wire master is enabled; this signal acts as the device chip enable. This enables communication between the 1-Wire master and the CPU.

**INTR**, Interrupt: This line goes to its active state whenever any one of the interrupt types has an active high condition and is enabled via the Interrupt Enable Register. The INTR signal is reset to an inactive state when the Interrupt Register is read.

**MR**, Master Reset: When this input is high, it clears all the registers and the control logic of the 1-Wire master, and sets INTR to its default inactive state, which is HIGH.

**$\overline{\text{RD}}$** , Read: This pin drives the bus during a read cycle. When the circuit is enabled, the CPU can read status information or data from the selected register by driving  $\overline{\text{RD}}$  low.  $\overline{\text{RD}}$  and  $\overline{\text{WR}}$  should never be low simultaneously; if they are,  $\overline{\text{WR}}$  takes precedence.

**$\overline{\text{WR}}$** , Write: This pin drives the bus during a write cycle. When  $\overline{\text{WR}}$  is low while the circuit is enabled, the CPU can write control words or data into the selected register.  $\overline{\text{RD}}$  and  $\overline{\text{WR}}$  should never be low simultaneously; if they are,  $\overline{\text{WR}}$  takes precedence.

## OPERATION – CLOCK DIVISOR

All 1-Wire timing patterns are generated using a base clock of 1.0 MHz. The 1-Wire Master will generate this clock frequency internally given an external reference on the CLK pin. The external clock must have a frequency from 3.2 to 128 MHz and a 50% duty cycle is preferred. The Clock Divisor Register controls the internal clock divider and provides the desired reference frequency. This is done in two stages: first a prescaler divides by 1, 3, 5, or 7, then the remaining circuitry divides by 2, 4, 8, 16, 32, 64, or 128.

### Clock Divisor Register

|           |     |   |   |      |      |      |      |      |
|-----------|-----|---|---|------|------|------|------|------|
| Addr. 04h | X   | X | X | DIV2 | DIV1 | DIV0 | PRE1 | PRE0 |
|           | MSB |   |   |      |      |      |      | LSB  |

The clock divisor must be configured before communication on the 1-Wire bus can take place. This register is set to 0x00h if a master reset occurs. Use the table below to find the proper register value based on the CLK reference frequency. For example, the user would write 0x10h to this location when providing a 15MHz input clock.

### Clock Divisor Register Settings for Input Clock Rates

| Min CLK Frequency (MHz) | Max CLK Frequency (MHz) | Divider Ratio | DIV3 | DIV2 | DIV1 | PRE1 | PRE0 |
|-------------------------|-------------------------|---------------|------|------|------|------|------|
| >3.2                    | 4.0                     | 4             | 0    | 1    | 0    | 0    | 0    |
| >4.0                    | 5.0                     | 5             | 0    | 0    | 0    | 1    | 0    |
| >5.0                    | 6.0                     | 6             | 0    | 0    | 1    | 0    | 1    |
| >6.0                    | 7.0                     | 7             | 0    | 0    | 0    | 1    | 1    |
| >7.0                    | 8.0                     | 8             | 0    | 1    | 1    | 0    | 0    |
| >8.0                    | 10.0                    | 10            | 0    | 0    | 1    | 1    | 0    |
| >10.0                   | 12.0                    | 12            | 0    | 1    | 0    | 0    | 1    |
| >12.0                   | 14.0                    | 14            | 0    | 0    | 1    | 1    | 1    |
| >14.0                   | 16.0                    | 16            | 1    | 0    | 0    | 0    | 0    |
| >16.0                   | 20.0                    | 20            | 0    | 1    | 0    | 1    | 0    |
| >20.0                   | 24.0                    | 24            | 0    | 1    | 1    | 0    | 1    |
| >24.0                   | 28.0                    | 28            | 0    | 1    | 0    | 1    | 1    |
| >28.0                   | 32.0                    | 32            | 1    | 0    | 1    | 0    | 0    |
| >32.0                   | 40.0                    | 40            | 0    | 1    | 1    | 1    | 0    |
| >40.0                   | 48.0                    | 48            | 1    | 0    | 0    | 0    | 1    |
| >48.0                   | 56.0                    | 56            | 0    | 1    | 1    | 1    | 1    |
| >56.0                   | 64.0                    | 64            | 1    | 1    | 0    | 0    | 0    |
| >64.0                   | 80.0                    | 80            | 1    | 0    | 0    | 1    | 0    |
| >80.0                   | 96.0                    | 96            | 1    | 0    | 1    | 0    | 1    |
| >96.0                   | 112.0                   | 112           | 1    | 0    | 0    | 1    | 1    |
| >112.0                  | 128.0                   | 128           | 1    | 1    | 1    | 0    | 0    |

## OPERATION – TRANSMITTING / RECEIVING DATA

Data sent and received from the 1-Wire master passes through the transmit/receive buffer location. The 1-Wire master is actually double buffered with separate transmit and receive buffers. Writing to this location connects the Transmit Buffer to the data bus, while reading connects the Receive Buffer to the data bus.

### Transmit Buffer (Write) / Receive Buffer (Read)

|           |       |       |       |       |       |       |       |       |
|-----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Addr. 01h | Data7 | Data6 | Data5 | Data4 | Data3 | Data2 | Data1 | Data0 |
|           | MSB   |       |       |       |       |       |       | LSB   |

### Writing a byte

To send a byte on the 1-Wire bus, the user writes the desired data to the Transmit Buffer. The data is then moved to the Transmit Shift Register where it is shifted serially onto the bus LSB first. A new byte of data can then be written to the Transmit Buffer. As soon as the Transmit Shift Register is empty, the data will be transferred from the Transmit Buffer and the process repeats. Each of these registers has a flag that may be used as an interrupt source. The Transmit Buffer Empty (TBE) flag is set when the Transmit Buffer is empty and ready to accept a new byte. As soon as a byte is written into the Transmit Buffer, TBE is cleared. The Transmit Shift Register Empty (TEMT) flag is set when the shift register has no data in it and is ready to accept a new byte. As soon as a byte of data is transferred from the Transmit Buffer, TEMT is cleared and TBE is set. Remember that proper 1-Wire protocol requires a reset before any bus communication.

### Reading a byte

To read data from a slave device, the device must first be ready to transmit data depending on commands already received from the CPU. Data is retrieved from the bus in a similar fashion to a write operation. The host initiates a read by writing to the Transmit Buffer. The data that is then shifted into the Receive Shift Register is the wired-AND of the written data and the data from the slave device. Therefore in order to read a byte from a slave device the host must write 0xFFh. When the Receive Shift Register is full the data is transferred to the Receive Buffer where it can be accessed by the host. Additional bytes can now be read by sending 0xFFh again. If the slave device is not ready to transmit, the data received will be identical to that which was transmitted. The receive registers can also generate interrupts. The Receive Shift Register flag (RSRF) is set at the start of data being shifted into the register and is cleared when the Receive Shift Register is emptied. The Receive Buffer flag (RBF) is set when data is transferred from the Receive Shift Register and cleared when the host reads the register. If RBF is set and another byte of data is received in the Receive Shift Register, the byte in the Receive Shift Register will wait until the user reads the Receive Buffer and the RBF flag is cleared. Thus, if both RSRF and RBF are set, no further transmissions should be made on the 1-Wire bus, or else data may be lost, as the byte in the Receive Shift Register will be overwritten by the next received byte. See the timing diagrams for details of the byte reception operation. Generating a 1-Wire reset on the bus is covered under Command Operations. Interrupt flags are explained in further detail under Interrupt Operations. Write and read operations are detailed in the timing diagrams.

## OPERATION – COMMANDS

The 1-Wire Master can generate two special commands on the bus in addition to reading and writing. The first is a 1-Wire reset, which must precede any command given on the bus. Secondly, the 1-Wire Master can be placed into Search ROM Accelerator mode to prevent the host from having to perform single bit manipulations of the bus during a Search ROM operation (0xF0h). For details on the reset or Search ROM command see [1]. Only one bit may be active at any time.

### Command Register (Read/Write)

|           |     |   |   |   |   |   |     |     |
|-----------|-----|---|---|---|---|---|-----|-----|
| Addr. 00h | X   | X | X | X | X | X | SRA | 1WR |
|           | MSB |   |   |   |   |   |     | LSB |

**1WR:** 1-Wire Reset. If this bit is set a reset will be generated on the 1-Wire bus. Setting this bit automatically clears the SRA bit. The 1WR bit will be automatically cleared as soon as the 1-Wire reset completes. The 1-Wire Master will set the Presence Detect interrupt flag (PD) when the reset is complete and sufficient time for a presence detect to occur has passed. The result of the presence detect will be placed in the interrupt register bit PDR. If a presence detect pulse was received PDR will be cleared, otherwise it will be set.

**SRA:** Search ROM Accelerator. When this bit is set, the 1-Wire Master will switch to Search ROM Accelerator mode. This mode presupposes that a Reset followed by the Search ROM command (0xF0h) has already been issued on the 1-Wire bus. For details on how the Search ROM is actually done in the 1-Wire system, please see [1]. Simply put, the algorithm specifies that the bus master reads two bits (a bit and its complement), then writes a bit to specify which devices should remain on the bus for further processing.

After the 1-Wire Master is placed in Search ROM Accelerator mode, the CPU must send 16 bytes to complete a single Search ROM pass on the 1-Wire bus. These bytes are constructed as follows:

#### first byte

|                |                |                |                |                |                |                |                |
|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|
| 7              | 6              | 5              | 4              | 3              | 2              | 1              | 0              |
| r <sub>3</sub> | x <sub>3</sub> | r <sub>2</sub> | x <sub>2</sub> | r <sub>1</sub> | x <sub>1</sub> | r <sub>0</sub> | x <sub>0</sub> |

#### et cetera

#### 16<sup>th</sup> byte

|                 |                 |                 |                 |                 |                 |                 |                 |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| 7               | 6               | 5               | 4               | 3               | 2               | 1               | 0               |
| r <sub>63</sub> | x <sub>63</sub> | r <sub>62</sub> | x <sub>62</sub> | r <sub>61</sub> | x <sub>61</sub> | r <sub>60</sub> | x <sub>60</sub> |

In this scheme, the index (values from 0 to 63, “n”) designates the position of the bit in the ROM ID of a 1-Wire device. The character “x” marks bits that act as a filler and do not require a specific value (don’t care bits). The character “r” specifies the selected bit value to write at that particular bit in case of a conflict during the execution of the ROM search.

For each bit position n (values from 0 to 63) the 1-Wire Master will generate three time slots on the 1-Wire bus. These are referenced as:

- b0 for the first time slot (read data)
- b1 for the second time slot (read data) and
- b2 for the third time slot (write data).

The 1-Wire Master determines the type of time slot b2 (write 1 or write 0) as follows:

b2 =  $r_n$  if conflict (as chosen by the host)  
 =  $b_0$  if no conflict (there is no alternative)  
 = 1 if error (there is no response)

The response bytes that will be in the data register for the CPU to read during a complete pass through a Search ROM function using the Search Accelerator consists of 16 bytes as follows:

**first byte**

|        |       |        |       |        |       |        |       |
|--------|-------|--------|-------|--------|-------|--------|-------|
| 7      | 6     | 5      | 4     | 3      | 2     | 1      | 0     |
| $r'_3$ | $d_3$ | $r'_2$ | $d_2$ | $r'_1$ | $d_1$ | $r'_0$ | $d_0$ |

**et cetera**

**16<sup>th</sup> byte**

|           |          |           |          |           |          |           |          |
|-----------|----------|-----------|----------|-----------|----------|-----------|----------|
| 7         | 6        | 5         | 4        | 3         | 2        | 1         | 0        |
| $r'_{63}$ | $d_{63}$ | $r'_{62}$ | $d_{62}$ | $r'_{61}$ | $d_{61}$ | $r'_{60}$ | $d_{60}$ |

As before, the index designates the position of the bit in the ROM ID of a 1-Wire device. The character “d” marks the discrepancy flag in that particular bit position. The discrepancy flag will be 1 if there is a conflict or no response in that particular bit position and 0 otherwise. The character “r” marks the actually chosen path at that particular bit position. The chosen path is identical to b2 for the particular bit position of the ROM ID.

To perform a Search ROM sequence one starts with all bits  $r_n$  being 0s. In case of a bus error, all subsequent response bits  $r'_n$  are 1's until the Search Accelerator is deactivated by writing 0 to bit 1 of the Command register. Thus, if  $r'_{63}$  and  $d_{63}$  are both 1, an error has occurred during the search procedure and the last sequence has to be repeated. Otherwise  $r'_n$  ( $n=0\dots63$ ) is the ROM code of the device that has been found and addressed. When the Search ROM process is complete the SRA bit should be cleared in order to release the 1-Wire Master from Search ROM Accelerator Mode.

For the next Search ROM sequence one re-uses the previous set  $r_n$  ( $n=0\dots63$ ) but sets  $r_m$  to 1 with “m” being the index number of the highest discrepancy flag that is 1 and sets all  $r_i$  to 0 with  $i>m$ . This process is repeated until the highest discrepancy occurs in the same bit position for two consecutive passes.

## EXAMPLE – ACCELERATED ROM SEARCH

In this example, the host will use the 1-Wire Master to identify four different devices on the 1-Wire bus. The ROM data of the devices is as shown (LSB first):

```
ROM1 = 00110101...
ROM2 = 10101010...
ROM3 = 11110101...
ROM4 = 00010001...
```

1. The host issues a reset pulse by writing 0x01h to the Command Register. All slave devices respond simultaneously with a presence detect.
2. The host issues a Search ROM command by writing 0x0Fh to the Transmit Buffer.
3. The host places the 1-Wire Master in Accelerator mode by writing 0x02 to the Command Register.
4. The host writes 0x00h to Transmit Buffer and reads the returning data from the Receive Buffer. This process is repeated for a total of 16 bytes. The data read will contain ROM4 in the r' locations and discrepancy bits set at d0 and d2 as shown (r' locations are underlined, most significant discrepancy is bolded ):

```
RECEIVED DATA 1 = 1000100100000001....
```

5. The host then de-interleaves the data to arrive at a ROM code of 00010001... with the last discrepancy at location d2.
6. The host writes 0x00h to the Command Register to exit Search Accelerator mode. The host is now free to send a command or read data directly from this device.
7. Steps 1-6 are now repeated to find the next device. The 16 bytes of data transmitted this time are identical to ROM4 up until the last discrepancy bit (d2 in this case) which is inverted and all data following is set to 0 as shown. The received data will contain ROM1 in the r' locations and bits d0 and d2 will be set again:

```
TRANSMITTED DATA 2 = 0000010000000000...
RECEIVED DATA 2 = 1000110100010001...
```

8. Since the most significant discrepancy (d2) did not change, the next most (d0) will be used and the process repeats. Further iterations contain the data as shown:

```
TRANSMITTED DATA 3 = 0100000000000000...
RECEIVED DATA 3 = 1110010001000100...
TRANSMITTED DATA 4 = 0101000000000000...
RECEIVED DATA 4 = 1111010100010001...
```

9. At this point, the most significant discrepancy (d1) did not change so the next most (d0) should be used. However, d0 has now been reached for the second time and since there are no less significant discrepancies, the search is complete having found a total of four devices.

## OPERATION – FLAGS AND INTERRUPTS

Flags from transmit, receive, and 1-Wire reset operations are located in the Interrupt Register. All flags except Receive Shift Register Full (RSRF) and Receive Buffer Full (RBF) are cleared when this register is read. These flags can generate an interrupt on the INTR pin if the corresponding enable bit is set in the Interrupt Enable Register.

### Interrupt Register (Read Only)

|              |     |   |      |     |      |     |     |    |
|--------------|-----|---|------|-----|------|-----|-----|----|
| Addr.<br>02h | X   | X | RSRF | RBF | TEMT | TBE | PDR | PD |
|              | MSB |   |      | LSB |      |     |     |    |

**PD:** Presence Detect. After a 1-Wire Reset has been issued, this flag will be set after the appropriate amount of time for a presence detect pulse to have occurred. The default state for this bit is 0. This bit is cleared when the Interrupt Register is read.

**PDR:** Presence Detect Result. When a Presence Detect interrupt occurs, this bit will reflect the result of the presence detect read – it will be 0 if a slave device was found, or 1 if no parts were found. The default state for this bit is 1. This bit is cleared when the Interrupt Register is read.

**TBE:** Transmit Buffer Empty. This flag will be set when there is nothing in the Transmit Buffer. The default state for this bit is 1. This bit is cleared when the Interrupt Register is read or data is written to the Transmit Buffer.

**TEMT:** Transmit Shift Register Empty. This flag will be set when there is nothing in the Transmit Shift Register. The default state for this bit is 1. This bit is cleared when the Interrupt Register is read or data is transferred from the Transmit Buffer.

**RBF:** Receive Buffer Full. This flag will be set when there is a byte waiting to be read in the Receive Buffer. This flag will be cleared when the byte is read from the Receive Buffer register. The default state for this bit is 0.

**RSRF:** Receive Shift Register Full. This flag will be set when there is a byte waiting in the receive shift register. This flag is cleared automatically when the data in the receive shift register is transferred to the receive buffer. The default state for this bit is 0.

The Interrupt Enable Register allows the system programmer to specify the source of interrupts which will cause the INTR pin to be active, and to define the active state for the INTR pin. When a Master Reset is received **all** bits in this register are cleared to 0 disabling all interrupt sources and setting the active state of the INTR pin to LOW. This means the INTR pin will be pulled high since all interrupts are disabled.

### Interrupt Enable Register (Read / Write)

|              |     |   |      |      |      |      |     |     |
|--------------|-----|---|------|------|------|------|-----|-----|
| Addr.<br>03h | X   | X | ERSF | ERBF | ETMT | ETBE | IAS | EPD |
|              | MSB |   |      | LSB  |      |      |     |     |

**EPD:** Enable Presence Detect Interrupt. If this bit is a 1, and the Presence Detect flag is set, then the INTR pin will become active whenever a 1-Wire Reset is sent and an appropriate amount of time has passed for a presence detect pulse to have occurred.

**IAS:** INTR Active State. This bit determines the active state for the INTR pin. If this bit is a 1, the INTR pin is active high; if it is a 0, the INTR pin is active low.

**EBTE:** Enable Transmit Buffer Empty Interrupt. If this bit is a 1, and the Transmit Buffer Empty flag is set, then the INTR pin will become active.

**ETMT:** Enable Transmit Shift Register Empty Interrupt. If this bit is a 1, and the Transmit Shift Register Empty flag is set, then the INTR pin will become active.

**ERBF:** Enable Receive Buffer Full Interrupt. If this bit is a 1, and the Receive Buffer Full flag is set, then the INTR pin will become active.

**ERSF:** Enable Receive Shift Register Full Interrupt. If this bit is a 1, and the Receive Shift Register Full flag is set, then the INTR pin will become active.

## I/O SIGNALING

The 1-Wire bus requires strict signaling protocols to insure data integrity. The four protocols used by the 1-Wire Master are the initialization sequence (Reset Pulse followed by Presence Pulse), Write 0, Write 1, and Read Data. The master initiates all of these types of signaling except the Presence Pulse.

The initialization sequence required to begin any communication with the bus slave is shown in Figure 1. A Presence Pulse following a Reset Pulse indicates the slave is ready to accept a ROM Command. The 1-Wire Master transmits a reset pulse for  $t_{RSTL}$ . The 1-Wire bus line is then pulled high by the pull-up resistor. After detecting the rising edge on the DQ pin, the slave waits for  $t_{PDH}$  and then transmits the Presence Pulse for  $t_{PDL}$ . The master samples the bus at  $t_{PDS}$  after the slave responds to test for a valid presence pulse. The reset time slot ends  $t_{RSTH}$  after the master releases the bus.

## 1-WIRE INITIALIZATION SEQUENCE (RESET PULSE AND PRESENCE PULSE) Figure 1

## WRITE TIME SLOTS

A write time slot is initiated when the 1-Wire Master pulls the 1-Wire bus line from a logic high (inactive) level to a logic low level. The master generates a Write 1 time slot by releasing the line at  $t_{LOW1}$  and allowing the line to pull up to a logic high level. The line is held low for  $t_{LOW0}$  to generate a Write 0 time slot. A slave device will sample the 1-Wire bus line between 15 and 60  $\mu\text{s}$  after the line falls. If the line is high when sampled, a Write 1 occurs. If the line is low when sampled, a Write 0 occurs (see Figure 2).

## READ TIME SLOTS

A read time slot is initiated when the 1-Wire Master pulls the bus low for at least 1  $\mu\text{s}$  and then releases it. If the slave device is responding with a 0 it will continue to hold the line low for up to 60  $\mu\text{s}$ , otherwise it will release it immediately. The master will sample the data  $t_{RDV}$  from the start of the read time slot. The master will end the read slot after a time of  $t_{SLOT}$ . See Figure 2 for more information.

## TIMING SPECIFICATIONS

| Symbol     | Parameter                 | Conditions        | Min | Max  | Units   |
|------------|---------------------------|-------------------|-----|------|---------|
| $t_{ADS}$  | Address Strobe Width      | Note 1,3          | 60  |      | ns      |
| $t_{AH}$   | Address Hold Time         | Note 1,3          | 0   |      | ns      |
| $t_{AR}$   | Address Latch to Read     | Note 1,3          | 60  |      | ns      |
| $t_{AS}$   | Address Setup Time        | Note 1,3          | 60  |      | ns      |
| $t_{AW}$   | Address Latch to Write    | Note 1,3          | 60  |      | ns      |
| $t_{DH}$   | Data Hold Time            | Note 1            | 30  |      | ns      |
| $t_{DS}$   | Data Setup Time           | Note 1            | 30  |      | ns      |
| $t_{ES}$   | Enable Setup Time         | Note 1            | 60  |      | ns      |
| $t_{HZ}$   | RD to Floating Data Delay | Note 1            | 0   | 100  | ns      |
| $t_{LOW0}$ | Write 0 Low Time          | $75 \tau$         | 75  | 94   | $\mu s$ |
| $t_{LOW1}$ | Write 1 Low Time          | $1 \tau$          | 1   | 1.25 | $\mu s$ |
| $t_{PDH}$  | Presence Detect High      |                   | 15  | 60   | $\mu s$ |
| $t_{PDI}$  | Presence Detect to INTR   | Note 1            | 0   | 100  | ns      |
| $t_{PDL}$  | Presence Detect Low       |                   | 60  | 240  | $\mu s$ |
| $t_{PDS}$  | Presence Detect Sample    | $30\tau$ (Note 2) | 30  | 37.5 | $\mu s$ |
| $t_{RD}$   | RD Strobe Width           | Note 1            | 125 |      | ns      |
| $t_{RDV}$  | Read Data Valid – 1 Wire  |                   | 15  |      | $\mu s$ |
| $t_{REC}$  | Recovery Time             |                   | 1   |      | $\mu s$ |
| $t_{REN}$  | Enable Hold Time from RD  | Note 1            | 20  |      | ns      |
| $t_{RSTH}$ | Reset Time High           | $500\tau$         | 500 | 625  | $\mu s$ |
| $t_{RSTL}$ | Reset Time Low            | $500\tau$         | 500 | 625  | $\mu s$ |
| $t_{RVD}$  | Delay from RD to Data     | Note 1            |     | 60   | ns      |
| $t_{SLOT}$ | Time Slot                 | $80\tau$          | 80  | 100  | $\mu s$ |
| $\tau$     | Timebase Period           |                   | 1   | 1.25 | $\mu s$ |
| $t_{WEN}$  | Enable Hold Time from WR  | Note 1            | 20  |      | ns      |
| $t_{WR}$   | WR Strobe Width           | Note 1            | 100 |      | ns      |
| $t_{WRST}$ | WR High to Reset          | Note 1            | 0   | 100  | ns      |

### NOTES:

1. These values will depend upon the process used to realize the circuit. Values shown are for example purposes only.
2. The 1-Wire Master will wait for a falling edge on the DQ line to be detected after a reset, for up to 60  $\mu s$ .
3. If  $\overline{ADS}$  is tied low,  $t_{AR}$  and  $t_{AW}$  are referred from  $t_{ES}$ ; thus  $\overline{RD}$  or  $\overline{WR}$  must occur at least
4.  $t_{ES} + t_{AR}$  or  $t_{ES} + t_{AW}$  after  $\overline{EN}$  goes low.

## REVISION HISTORY

### 0.1 – June 15, 1999

1. First release

### 0.2 – July 12, 1999

2. Clarification added that  $\overline{RD}$  and  $\overline{WR}$  should never be low simultaneously; if they are,  $\overline{WR}$  takes precedence.
3. First draft of search ROM driver code example added in section 6.0.

### 0.3 – August 17, 1999

1.  $\overline{EN}$  is **not** latched by  $\overline{ADS}$ ;  $\overline{ADS}$  only controls an internal address latch, which may be made transparent by tying  $\overline{ADS}$  low.  $\overline{EN}$  is a level-enabled signal, and does not need to be latched.
2. Changed lower clock rate to 3.1 MHz. Updated timing specifications to reflect this.
3. Removed DIVSEL0, DIVSEL1, and DIVSEL2 pins. Clock division selection is now performed by writing to the Clock Divisor Register; this makes it necessary to add an additional address line, A2, in order to select this register.
4. The 1-Wire master is now double-buffered for receive and transmit operations; the data register is no longer a physical register but two registers – the transmit buffer and the receive buffer. These two buffers are memory mapped to the same location, where a write operation selects the transmit buffer, and a read selects the receive buffer. Flags TBE, TEMT, RBF, and RSRF are defined to signal when buffers are empty or full.
5. Setting the 1-Wire reset bit in the command register now automatically disables the Search ROM accelerator bit.
6. Interrupts are automatically cleared by reading the interrupt register.
7. The result of a presence detect is now reported in the Interrupt Register instead of in the data register. This allows the PD interrupt service routine to read the result of a presence detect interrupt when it reads the interrupt register.
8. Changed the way the Interrupt and Interrupt Enable Registers work – it was backward initially. The Interrupt Register now is more of a status register, whose bits get ANDed with the Interrupt Enable Register to determine if any of the flags set in that register cause the INTR pin to go active. The active state of the INTR pin is now programmable; default is HIGH on Master Reset.
9. Removed example code. Will need to be rewritten to comprehend changes made in specification of the hardware device.

### 0.4 – August 20, 1999

1. Clarified that Master Reset causes INTR to go to its inactive state. This is further clarified in section 4.5 by defining the reset state of the Interrupt Enable Register as cleared to all zeros, masking all interrupt sources and defining the active state of the INTR pin as low. This implies that INTR will go HIGH upon MR.
2. By restricting the lower clock frequency to 3.2MHz, internal timing can now be between 1uS and 1.25uS.
3. Corrected several grammatical, typographical, and spelling errors.
4. Since the internal clock is the result of different division ratios, the duty cycle may not be 50%. This is not a problem for the circuit, so all references to high and low times of the internal timebase have been deleted. The internal clock period is now referred to as  $\tau$ , to simplify timing diagrams.
5. Timing diagrams have been updated to reflect changes in nomenclature, and to clarify timing.
6. Note 4 added to timing specification table.
7. Section 6 renamed to “Applications Hints and Examples”. Notes were added in this section regarding 1-Wire wave shaping and power management.

**0.5 – August 24, 1999**

1. In Section 1.0, changed “four registers” to “five registers”, to reflect current actual register count. Note that receive and transmit registers are actually 1 register in the memory map.
2. Corrected block diagram to reflect 1.25us timebase maximum.
3. Removed voltage specifications on logic high and low in Section 3.0, as these will be process-specific.
4. Changed lower clock rate to 3.2MHz in the text description of the CLK pin.
5. Removed  $t_R$  specification.
6.  $t_{PDS}$  is now specified from the falling edge of the DQ line after the line has been released by the master. The master will wait for up to 60  $\mu s$  to detect a falling edge; but if the edge occurs before 60  $\mu s$ , the master will wait 30  $\mu s$  after that edge to sample the data line to read the presence detect.
7. Fixed errors in timing specification table left over from the change to maximum internal timebase period of 1.25uS.

**0.6 – September 17, 1999**

1. TBE and TEMT default states changed to 1 instead of 0, to reflect their actual state (empty) upon a master reset.

**1.0 – September 20, 1999**

1. Changed the operation of the interrupt register. The RBF and RSRF flags are no longer automatically cleared when a read operation is performed on the Interrupt Register. Doing so would allow for data to be overwritten if the interrupt handler did not do a read of the receive buffer immediately following the interrupt. These flags are now cleared when the data has actually been read or shifted out.
2. Revision 1.000 of the VHDL code is complete, and this specification reflects the current operation of that VHDL code. Thus, the revision number for this specification is changed to 1.0 and t OPERATION.

**31 October, 1999.**

1. Revision 1.2 of the datasheet complete. Format has been changed to look like a standard DS datasheet. Verilog version of the code is also complete. Both types undergoing testing on the bench.
