# High-Voltage, $\pm 15 k V$ ESD-Protected Electroluminescent Lamp Driver 

## General Description

The MAX4990E high-voltage DC-AC converter is ideal for driving electroluminescent (EL) lamps. The MAX4990E features a wide +2.4 V to +5.5 V input range that allows the device to accept a wide variety of voltage sources such as single-cell lithium-ion (Li+) batteries and higher voltage battery chargers. The lamp outputs of the device generate up to 250V peak-topeak output voltage for maximum lamp brightness.
The MAX4990E utilizes an inductor-based boost converter to generate the high voltage necessary to drive an EL lamp. The boost-converter switching frequency is set with the combination of an external capacitor connected from SW to GND and an external resistor connected from SLEW to GND.
The MAX4990E uses a high-voltage full-bridge output stage to convert the high voltage generated by the boost converter to an AC waveform suitable for driving the EL panel. The EL output switching frequency is set with the combination of an external capacitor connected from EL to GND and an external resistor connected from SLEW to GND.
The MAX4990E uses a proprietary acoustic noisereduction circuit that controls the slew rate of the AC voltage, reducing audible noise from the EL panel. The slew rate is set with an external resistor connected from SLEW to GND.
The MAX4990E features an EL lamp dimming control (DIM) that allows the user to set the EL output voltage with a PWM signal, a DC analog voltage, or a resistor connected from the DIM input to GND. A capacitor placed in parallel to the resistor on DIM allows the user to program a slow turn-on/-off time that generates a soft fade-on/fade-off effect of the EL lamp.
The MAX4990E enters a low-power shutdown mode (100nA max) when the EN and DIM inputs are connected to GND. The MAX4990E also enters thermal shutdown if the die temperature rises above $+158^{\circ} \mathrm{C}$.
The MAX4990E is available in a space-saving, 14-pin, $3 \mathrm{~mm} \times 3 \mathrm{~mm}$ TDFN package and is specified over the extended $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ operating temperature range.

## Typical Application Circuits appear at end of data sheet.

## ABSOLUTE MAXIMUM RATINGS

(All voltages referenced to GND.)

JA ................................................................................ $41^{\circ} \mathrm{C} / \mathrm{W}$
Operating Temperature Range ........................... $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
Junction Temperature ...................................................... $+150^{\circ} \mathrm{C}$
Storage Temperature Range ............................. $65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$
Lead Temperature (soldering, 10s) ................................. $+300^{\circ} \mathrm{C}$

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Pin Description

| PIN | NAME | FUNCTION |
| :---: | :---: | :--- |
| 1 | SLEW | High-Voltage Slew-Rate Control. Connect an external resistor, RSLEW, to GND to set the slew rate of <br> the VA and VB high-voltage outputs. |
| 2 | EN | Enable Input. Drive EN > +1.2V and DIM > +0.35V to turn on the device. Drive EN < +0.2V and DIM < <br> +0.15V to turn off the device. |
| 3 | DIM | EL Panel Dimming Control. Apply a PWM signal or DC analog control signal, or connect a resistor to <br> GND to adjust peak-to-peak output voltage. Use DIM together with EN to control device shutdown <br> (see Shutdown section). |
| 4 | SL | EL Voltage Switching Frequency. Connect an external capacitor, CEL, to GND or drive with an external <br> oscillator to set the switching frequency of the VA and VB high-voltage outputs. Connect EL to GND to <br> shut off the EL oscillator. Drive EL high to keep alternatively VA or VB output high. |
| 5 | Boost-Converter Switching Frequency. Connect an external capacitor, CSW, to GND or drive with an <br> external oscillator to set the switching frequency of the boost converter. Connect SW to GND to shut <br> off the boost oscillator. Do not keep SW high to avoid LX shorting to GND, which causes the internal <br> die temperature to increase. The MAX4990E is protected by entering a themal-shutdown state. (See <br> the Thermal Short-Circuit Protection section.) |  |
| 6 | VDD | Power-Supply Voltage |
| 7 | GND | Ground |
| 8 | LX | Internal Switching DMOS Drain Connection. Connect LX to a switching inductor and an anode of a <br> rectifying diode. |
| $9,11,13$ | N.C. | No Connection. Leave N.C. unconnected. |
| 10 | CS | High-Voltage Supply. Connect CS to output capacitor of boost converter. |
| 12 | VB | High-Voltage EL Panel Output. Connect to non-VA side of EL lamp. |
| 14 | VA | High-Voltage EL Panel Output. Connect to non-VB side of EL lamp. |
| EP | EP | Exposed Pad. Connect exposed pad to GND. |

## Detailed Description

The MAX4990E high-voltage DC-AC converter is ideal for driving EL lamps. The MAX4990E features a wide +2.4 V to +5.5 V input range that allows the device to accept a wide variety of voltage sources such as single cell Li+ batteries and higher voltage battery chargers. The lamp outputs of the device generate up to 250 V peak-to-peak output voltage for maximum lamp brightness.
The MAX4990E utilizes an inductor-based boost converter that allows for the use of a $220 \mu \mathrm{H}$ inductor to generate the high voltage necessary to drive an EL lamp. The boost converter switching frequency is set with the combination of an external capacitor connected from the SW input to GND and an external resistor connected from SLEW to GND. Applying a PWM signal to the SW input allows the switching frequency of the boost converter to take the frequency of the PWM signal.

The MAX4990E uses a high-voltage full-bridge output stage to convert the high voltage generated by the boost converter to an AC waveform suitable for driving the EL panel. The EL output switching frequency is set with the combination of an external capacitor connected from EL to GND and an external resistor connected from SLEW to GND. The MAX4990E allows programmability of the EL Lamp output frequency by applying a clock signal to the EL input. Applying a clock signal to the EL input allows the switching frequency of the lamp to take the frequency of the clock signal divided by 4 to switch at the EL input frequency divided by 4.
The MAX4990E uses a proprietary acoustic noisereduction circuit to control the slew rate of the AC voltage, reducing audible noise from the EL panel. The slew rate is set with an external resistor connected from SLEW to GND.
The MAX4990E enters a low-power shutdown mode (100nA max) when EN and DIM inputs are connected

## High-Voltage, $\pm 15 k V$ ESD-Protected Electroluminescent Lamp Driver

to GND. The MAX4990E also enters thermal shutdown if the die temperature rises above $+158^{\circ} \mathrm{C}$.
The MAX4990E features an EL lamp dimming control (DIM) that allows the user to set the EL output voltage with a PWM, DC analog voltage, or a resistor connected to GND. A capacitor placed in parallel to the resistor on the DIM input allows the user to program a slow turn-on/-off time of the MAX4990E's outputs to generate a soft fade-on/fade-off effect of the EL lamp.
The high-voltage outputs are ESD protected up to $\pm 15 \mathrm{kV}$ Human Body Model, $\pm 15 \mathrm{kV}$ Air-Gap Discharge, and $\pm 4 \mathrm{kV}$ Contact Discharge, as specified in the IEC 61000-4-2 specification.

## EL Output Voltage

The slew rate, frequency, and peak-to-peak voltage of the MAX4990E EL lamp outputs are programmed through a combination of external components and/or DC inputs.

The device uses resistor RSLEW to set the bias current used as a reference current for the MAX4990E internal circuitry. The reference current directly affects the slew rate of the EL lamp output. Increasing the value of RSLEW decreases the slew rate, and decreasing the value of RSLEW increases the slew rate. (See the RSLEW Resistor Selection section on how to select RSLEW.)
The MAX4990E EL lamp output frequency uses an internal EL oscillator to set the desired frequency. The output frequency is adjusted by either 1) the combination of a resistor from SLEW to GND and an external capacitor from the EL input to GND, or 2) by driving a clock signal directly into the EL input. (See the CEL Capacitor Selection section for choosing the CEL capacitor value.)
The peak-to-peak voltage of the EL lamp output is varied from 70VP-p to 250Vp-p by applying an external DC voltage ranging from +0.35 V to +1.3 V to the DIM input.

# High－Voltage，$\pm 15 k V$ ESD－Protected Electroluminescent Lamp Driver 

Increasing the voltage on the DIM input increases the peak－to－peak voltage，and decreasing the voltage on the input decreases the peak－to－peak voltage．The EL lamp peak－to－peak voltage is also adjusted by applying a PWM signal to the DIM input．The duty cycle of the PWM determines the EL lamp output peak－to－peak volt－ age．As the duty cycle is increased，the peak－to－peak output voltage is increased，and as the duty cycle is decreased，the peak－to－peak voltage is decreased．The MAX4990E also features a slow turn－on and slow turn－off time feature that is enabled by connecting a resistor and capacitor from DIM to GND（see the Typical Application Circuits and the RDIM Resistor and CDIM Capacitor Selection section）．This slow turn－on／－off feature causes the peak－to－peak voltage of the EL outputs to slowly rise from zero to the maximum set value when the device is enabled．This feature also causes the peak－to－peak volt－ age of the EL outputs to fall from the maximum set value to zero when the device is placed into shutdown．The slow rise and fall of the peak－to－peak EL output voltage creates a soft fade－on and fade－off of the EL lamp， rather than an abrupt change in brightness．

## Boost Converter

The MAX4990E boost converter consists of an external inductor from VDD to the LX input，an internal DMOS switch，an external diode from LX to the CS output，an external capacitor from the CS output to GND，and the EL lamp，CLAMP，connected to the EL lamp outputs． When the DMOS switch is turned on，LX is connected to GND，and the inductor is charged．When the DMOS switch is turned off，the energy stored in the inductor is transferred to the capacitor CCS and the EL lamp．
Note：Keeping SW high shorts LX to GND，causing the internal die temperature to increase．The MAX4990E is protected by entering a thermal－shutdown state（See the Thermal Short－Circuit Protection section．）
The MAX4990E boost converter frequency uses an internal switch oscillator to set the desired frequency of the boost converter．The boost converter frequency is adjusted by either 1）the combination of a resistor from SLEW to GND and an external capacitor from SW to GND，or 2）by driving a PWM signal directly into the SW input．When SW is driven with an external PWM signal at a suggested $90 \%$ duty cycle，the boost converter fre－ quency is changed to the frequency of the external PWM signal．（See the CSW Capacitor Selection section for choosing the CSW capacitor value．）

## Dimming Control

The MAX4990E features a dimming control input，DIM， that controls the peak－to－peak voltage on the lamp out－ puts $V_{A}$ and $V_{B}$ ．DIM is controlled by a resistor con－
nected from the DIM input to GND，a PWM signal applied to the DIM input，or a DC voltage applied to the DIM input．（See the RDIM Resistor and CDIM Capacitor Selection section．）
The duty cycle of a PWM signal to the DIM input is internally translated into a DC voltage with the 0 to +1.22 V range．The DIM input accepts the frequency range of 200 kHz to 1 MHz ．As the duty cycle increases， the peak－to－peak voltage of the output increases，and as the duty cycle decreases，the peak－to－peak voltage of the output decreases．
The peak－to－peak voltage is adjusted by applying a DC voltage to the DIM input．Increasing the voltage on DIM increases the peak－to－peak output，and decreasing the voltage on DIM decreases the peak－to－peak output voltage．
The DIM input，in combination with the EN input，con－ trols the shutdown mode of the MAX4990E shutdown． （See the Shutdown section．）

Slow Turn－On，Slow Turn－Off
The MAX4990E provides a slow turn－on／－off feature by connecting a resistor in parallel with a capacitor con－ nected from the DIM input to GND（see the RDIM Resistor and CDIM Capacitor Selection section）．When EN is driven high，the reference current IB（set by RSLEW）is used to charge capacitor CDIM．When EN is driven to GND，IB is removed，and the voltage on the capacitor CDIM and resistor decays with a time con－ stant of RDIM $\times$ CDIM．A slow turn－on effect is seen by driving EN high．The slow rise and fall of the voltage on DIM during transitions on the EN input modulates the peak－to－peak voltage of the EL outputs，creating a soft fade－on／－off effect at the EL lamp．

## Shutdown

The MAX4990E features an enable logic input，EN，to enable and disable the device．To enable the device， apply +1.2 V or greater to the EN input and +0.35 V or greater to the DIM input．To place the device in shut－ down，apply +0.2 V or less to the EN input，and +0.15 V or less to the DIM input．

## Undervoltage Lockout（UVLO）

The MAX4990E has a UVLO threshold of＋2．1V（typ）． When VDD falls below＋2．1V（typ），the device enters a nonoperative mode．

## Thermal Short－Circuit Protection

The MAX4990E enters a nonoperative mode if the inter－ nal die temperature of the device reaches or exceeds $+158^{\circ} \mathrm{C}$（typ）．The device turns back on when the inter－ nal die temperature cools to $+150^{\circ} \mathrm{C}$ ．

# High-Voltage, $\pm 15 k V$ ESD-Protected Electroluminescent Lamp Driver 

## 土15kV ESD Protection

As with all Maxim devices, ESD-protection structures are incorporated on all pins to protect against electrostatic discharges encountered during handling and assembly. The EL lamp driver outputs of the MAX4990E have extra protection against static electricity. Maxim's engineers have developed state-of-the-art structures to protect these pins against ESD of $\pm 15 \mathrm{kV}$ without damage. The ESD structures withstand high ESD in all states: normal operation, shutdown, and powered down. After an ESD event, the MAX4990E keep working without latchup or damage.
ESD protection can be tested in various ways. The transmitter EL lamp outputs of the MAX4990E are characterized for protection to the following limits:

- $\pm 15 \mathrm{kV}$ using the Human Body Model
- $\pm 4 \mathrm{kV}$ IEC 61000-4-2 Contact Discharge
- $\pm 15 \mathrm{kV}$ IEC 61000-4-2 Air-Gap Discharge

## ESD Test Conditions

ESD performance depends on a variety of conditions. Contact Maxim for a reliability report that documents test setup, test methodology, and test results.

## Human Body Model

Figure 1a shows the Human Body Model, and Figure 1 b shows the current waveform it generates when discharged into a low impedance. This model consists of a 100pF capacitor charged to the ESD voltage of interest, which is then discharged into the test device through a $1.5 \mathrm{k} \Omega$ resistor.

IEC 61000-4-2
The IEC 61000-4-2 standard covers ESD testing and performance of finished equipment. However, it does not specifically refer to integrated circuits. The MAX4990E assists in designing equipment to meet IEC 61000-4-2 without the need for additional ESD-protection components.
The major difference between tests done using the Human Body Model and IEC 61000-4-2 is higher peak current in IEC 61000-4-2 because series resistance is lower in the IEC 61000-4-2 model. Hence, the ESD withstand voltage measured to IEC 61000-4-2 is generally lower than that measured using the Human Body Model. Figure 1c shows the IEC 61000-4-2 model, and Figure 1d shows the current waveform for IEC 61000-42 ESD Contact Discharge test.

## Machine Model

The machine model for ESD tests all pins using a 200pF storage capacitor and zero discharge resistance.
The objective is to emulate the stress caused when I/O pins are contacted by handling equipment during test and assembly. Of course, all pins require this protection.
The Air-Gap test involves approaching the device with a charged probe. The Contact Discharge method connects the probe to the device before the probe is energized.

## Design Procedure

## Lx Inductor Selection

The recommended inductor values are $220 \mu \mathrm{H} / 330 \mu \mathrm{H}$. For most applications, series resistance (DCR) should be below $8 \Omega$ for reasonable efficiency. Do not exceed the inductor's saturation current.

## RsLew Resistor Selection

To help reduce audible noise emission by the EL lamp, the MAX4990E features a slew-rate control input (SLEW) that allows the user to set the slew-rate of the high-voltage outputs, $\mathrm{V}_{\mathrm{A}}$ and $\mathrm{V}_{\mathrm{B}}$, by connecting a resistor, RSLEW, from the SLEW input to GND. RSLEW precisely sets the reference current IB that is used to charge and discharge the capacitances at the SW input and EL input, and is used as a reference current for internal circuitry. The reference current is related to RsLew by the following equation: $I_{B}=1 \mathrm{~V} /$ RSLEW. Decreasing the value of RSLEW increases $\mathrm{IB}_{\mathrm{B}}$ and increases the slew rate at the EL lamp output. Increasing the value of RSLEW decreases IB and decreases the slew rate at the EL lamp output. The output slew rate is related to RsLEW by the following equation:

$$
\text { SlewRate }\left(\frac{\mathrm{V}}{100 \mu \mathrm{~s}}\right)=\frac{11.25}{\mathrm{R}_{\mathrm{SLEW}}(\mathrm{M} \Omega)}
$$

The ideal value for a given design varies depending on lamp size and mechanical enclosure. Typically, the best slew rate for minimizing audible noise is between $10 \mathrm{~V} / 100 \mu \mathrm{~s}$ and $20 \mathrm{~V} / 100 \mu \mathrm{~s}$. This results in RsLew values ranging from $1.125 \mathrm{M} \Omega$ to $0.5625 \mathrm{M} \Omega$. For example, if the desired slew rate is $20(\mathrm{~V} / 100 \mu \mathrm{~s})$, this leads to an RsLEW resistor value in $\mathrm{M} \Omega$ of RSLEW $=11.25 / 20 \mathrm{~V}=0.5625 \mathrm{M} \Omega$.
Note: Connecting RSLEW to GND will not damage the device. However, for the device to operate correctly, RSLEW should be in the $100 \mathrm{k} \Omega$ to $2.2 \mathrm{M} \Omega$ range.
RsLEW also affects the frequency of the boost converter (see the CSW Capacitor Selection), the frequency of the EL lamp (see the CEL Capacitor Selection section), and the peak-to-peak voltage of the EL lamp.

The peak-to-peak voltage is adjusted by connecting a resistor from the SLEW input to GND together with a resistor from the DIM input to GND. The equation relating the peak-to-peak voltage to the resistors is the following:

$$
\mathrm{V}_{\mathrm{P}-\mathrm{P}}=200 \times \frac{\mathrm{R}_{\mathrm{DIM}}}{R_{\mathrm{SLEW}}}
$$

RDIM Resistor and CdIm Capacitor Selection
The MAX4990E provides a slow turn-on/-off feature by connecting a resistor in parallel with a capacitor connected from the DIM input to GND. The reference current $\mathrm{I}_{\mathrm{B}}$ is used to charge the resistor and capacitor. When EN is driven to GND, $I_{B}$ is removed, and the voltage across the capacitor and resistor decay with a time constant of RC that provides a slow turn off of the EL

## High-Voltage, $\pm 15 k V$ ESD-Protected Electroluminescent Lamp Driver

lamp outputs. A slow turn-on effect is produced by driving EN high. Slow turn-on/-off time is related by the following equation:

$$
\begin{aligned}
& \text { ton }=2.6 \times \text { RDIM } \times \text { CDIM } \\
& \text { tOFF }=1.2 \times \text { RDIM } \times \text { CDIM }
\end{aligned}
$$

For this equation to be valid, RDIM/RsLEW must be $\leq 1.3$.

## Ccs Capacitor Selection

Ccs is the output of the boost converter and provides the high-voltage source for the EL lamp. Connect a 3.3 nF capacitor from CS to GND and place as close to the CS input as possible. When using an inductor value larger than $220 \mu \mathrm{H}$, it may be necessary to increase the Ccs. For a LX $=470 \mu \mathrm{H}$ and Clamp $=20 \mathrm{nF}$, a Ccs ranging from 3.3 nF to 6.8 nF is recommended.

## Cel Capacitor Selection

The MAX4990E EL lamp output frequency is set by connecting a capacitor from the EL input to GND together with a resistor from SLEW to GND or by driving the EL input with an external clock ( 0 to +1.5 V ). The EL lamp output frequency is related to the CEL capacitor by the following equation:

$$
\mathrm{f}_{\mathrm{EL}}=\frac{0.0817}{R_{S L E W} \times \mathrm{C}_{E L}}
$$

For example, an RsLew $=375 \mathrm{k} \Omega$ and a Cel capacitor value of 1000 pF equals an EL lamp output frequency of $F_{E L}=217 \mathrm{~Hz}$.

## Csw Capacitor Selection

The boost converter switching frequency is set by connecting a capacitor from the SW input to GND, together with the resistance from the SLEW input to GND, or driving the SW input with an external clock ( 0 to +1.5 V ). The switching frequency of the boost converter is related to the capacitor from SW to GND by the following equation:

$$
\mathrm{f}_{\mathrm{SW}}=\frac{3.61}{R_{\text {SLEW }} \times \mathrm{C}_{\text {SW }}}
$$

Connect the SW input to GND to turn the switch oscillator of the boost converter off. Although the optimal fsw depends on the inductor value, the suggested fsw range is 20 kHz to 150 kHz .
Note: Driving SW with a logic-high causes LX to be driven to GND. Keeping SW high shorts LX to GND, causing the internal die temperature to increase. The MAX4990E is protected by entering a thermal-shutdown state. (See the Thermal Short-Circuit Protection section.)

## CB Capacitor Selection $^{\text {Con }}$

Bypass VDD with a $0.1 \mu \mathrm{~F}$ ceramic capacitor as close to the IC as possible and a $4.7 \mu \mathrm{~F}$ ceramic capacitor as close to the inductor as possible

## Diode Selection

Connect a diode, $\mathrm{D}_{1}$, from the LX node to CS to rectify the boost voltage on CS. The diode should be a fastrecovery diode that is tolerant to +150 V .

## EL Lamp Selection

 EL lamps have a capacitance of approximately 2.5 nF to 3.5 nF per square inch. The MAX4990E effectively charges capacitance ranging from 2 nF to 20 nF .
## Applications Information

PCB Layout
Keep PCB traces as short as possible. Ensure that bypass capacitors are as close to the device as possible. Use large ground planes where possible.
