

XGA Flat Panel Controller

FEATURES

General

- Auto configuration of sampling clock frequency, phase, H/V center, as well as white balance.
- Auto detection of present or non-present or over range sync signals and their polarities.
- Composite sync separation and odd/even field detection of interlaced video.
- No external memory required.
- On-chip output PLL provide clock frequency fine-tune (inverse, duty cycle and delay).
- Serial 2-wire I²C host interface.
- 3.3V supplier, 5V I/O tolerance in 128-pin PQFP package.

Input Processor

- Single RGB (24-bit) input rates up to 100MHz.
- Support both non-interlaced and interlaced RGB graphic input signals.
- YUV 4:2:2 or YUV 4:1:1 (CCIR601/CCIR656) interlaced video input.
- Glue-free connection to Philips SAA711x digital video decoder.
- Built-in YUV to RGB color space converter.
- Compliant with digital LVDS/PanelLink TMDS input interface.
- PC input resolution up to XGA 1024x768 @85Hz.

Video Processor

- Independent programmable Horizontal and Vertical scaling up ratios from 1 to 32
- Flexible de-interlacing unit for digital YUV video input data.
- Zoom to full screen resolution of de-interlaced YUV video data stream.
- Built-in programmable gain control for white balance alignments.
- Built-in programmable 8-bit gamma correction table.
- Built-in programmable temporal color dithering.
- Built-in programmable interpolation look-up table.
- Support smooth panning under viewing window change.

Output Processor

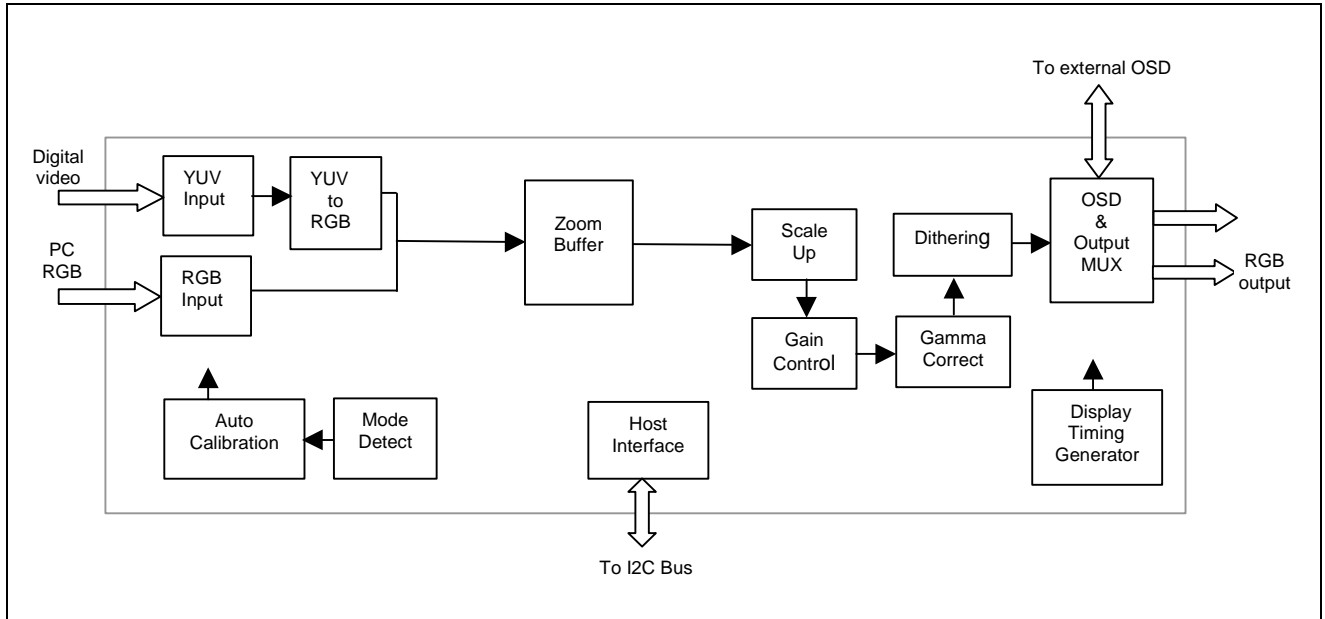

- Single pixel (18/24-bit) or Dual pixel (36/48-bit) per clock digital RGB output.
- Built-in output timing generator with programmable clock and H/V sync.
- Support VGA/SVGA/XGA display resolution.
- Overlay input interface with external OSD controller.
- Double scan capability for interlaced input.

GENERAL DESCRIPTION

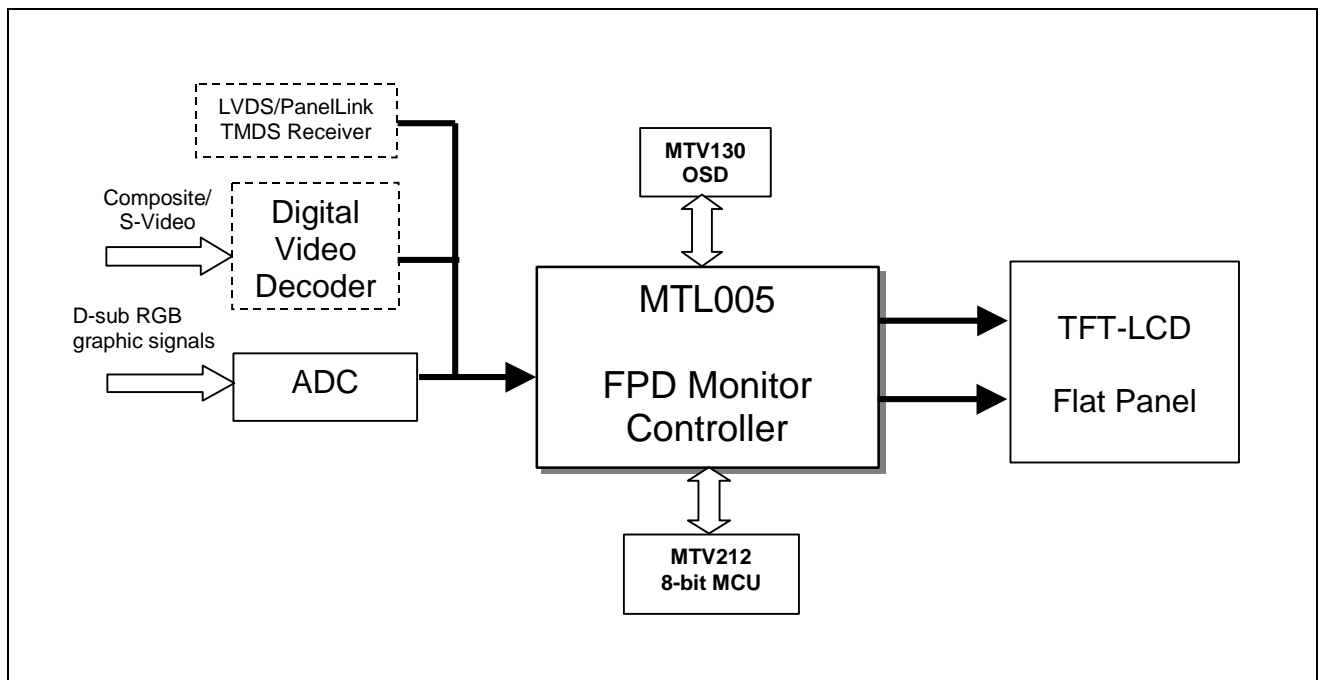

The MTL005 Flat Panel Display (FPD) Controller is a low-cost input format converter for TFT-LCD Monitor or LCD TV application which accepts 15-pin D-sub RGB graphic signals (through ADC), YUV signals from digital video decoder or digital RGB graphic signals from PanelLink TMDS receiver. It comprises a RGB/YUV input processor, video scaling up processor, OSD input interface and output display processor in 128-pin PQFP.

3. FUNCTIONAL DESCRIPTION

3.1 Input Processor

General Description

The function of Input Interface is to provide the interface between MTL005 and external input devices. It can process both non-interlaced and interlaced RGB graphic input, YUV video input, and digital RGB input compliant with digital LVDS/PanelLink TMDS interface. It also contains the built-in YUV to RGB color space converter.

3.1.1 RGB Input Format

Since MTL005 is a low cost solution, the RGB input port can only work in Single Pixel mode (24 bits). The R/G/BIN ports are sampled at the rising edge of the RGB input clock.

3.1.2 TMDS Input Format

The Digital RGB input port works likewise as described in Sec 3.1.1 except one more input pin is needed: Digital Input Enable DIEN.

With a single pixel input interface, the supported format is up to true color, including 18 bit/pixel or 24 bit/pixel.

3.1.3 YUV Input Format

The YUV input port supports interlaced video data from the most common video decoder ICs like SAA711x. The 16 bit data bus is shared with the ports RIN[7:0] and GIN[7:0]. The 16 bit data is sampled at the rising edge of the shared video clock VPCLK when the shared data enable HREF is active. The supported formats are YUV4:1:1 and YUV4:2:2 with CCIR601/CCIR656 standard.

3.1.4 Input HSYNC Path

Besides the pin HSYNC, MTL005 provides another pin RAWHS to support Sync Processor in MTL005. Generally, the HSYNC generated by an ADC may have a very narrow pulse width and a different polarity from the original HSYNC provided by the source. The RAWHS input provides the path of original HSYNC connection to MTL005, which makes Sync Processor in MTL005 work correctly.

3.1.5 YUV to RGB Converter

It is used to convert YCbCr format into RGB format. The basic equations are as follows:

$$\begin{aligned}R &= Y + 1.371(Cr - 128) \\G &= Y - 0.698(Cr - 128) - 0.336(Cb - 128) \\B &= Y + 1.732(Cb - 128)\end{aligned}$$

3.1.6 De-interlace mode

For interlace input, MTL005 features several de-interlacing algorithms for processing interlaced video data depending on the type of input images.

Toggle Mode

In this mode, only one field is displayed at the time. First field and second field is toggled displayed. The missing lines are calculated from duplicating the neighbor lines.

Spatial Mode

In this mode, two fields are toggled displayed, just like Toggle mode. The missing lines are calculated from interpolating the neighbor lines. An average good quality for still and moving pictures is achieved in this mode.

3.1.7 Sync Processor

The V/H SYNC processing block performs the functions of Composite signal separation/insertion, SYNC inputs presence check, frequency counting, polarity detection and control. It contains a de-glitch circuit to filter out any pulse shorter than one OSC period treated as noises on V/H SYNC pulses.

V/H SYNC Frequency Counter

MTL005 can measure VSYNC/HSYNC frequency counted in proper clocks and save the information in registers. Users can read it out to calculate VSYNC/HSYNC frequency as in the following formulas:

$$f_{\text{vsync}} = f_{\text{osc}} / N_{\text{vsync}} \times 1/256$$
$$f_{\text{hsync}} = f_{\text{osc}} / N_{\text{hsync}} \times 8$$

,Where

- f_{vsync} : VSYNC frequency
- f_{hsync} : HSYNC frequency
- f_{osc} : oscillator clock with 14.31818 MHz
- N_{vsync} : counted number of VSYNC
- N_{hsync} : counted number of HSYNC

V/H SYNC Presence Check

This function checks the input VSYNC, where Vpre flag is set when VSYNC is over 40Hz or cleared when VSYNC is under 10Hz, and the input HSYNC, where Hpre flag is set when HSYNC is over 10Khz or cleared when HSYNC is under 10Hz.

V/H Polarity Detect

This function detects the input VSYNC/HSYNC high and low pulse duty cycle. If the high pulse duration is longer than that of the low pulse, the negative polarity is asserted; otherwise, positive polarity is asserted.

Composite SYNC separation/insertion

MTL005 continuously monitors the input HSYNC. If the input VSYNC can be extracted from it, a CVpre flag is set. MTL005 can insert HSYNC pulse during Composite VSYNC's active time and the insertion frequency can adapt to original HSYNC's.

3.1.8 Auto Tune

Auto Tune function consists of Auto Position automatically centering the screen and Auto Calibration containing Phase Calibration, Histogram, Min/Max Value, and Pixel Grab described as below. With this auto adjustment support it is possible to measure the correct phase, frequency, gain, and offset of ADC. The horizontal and vertical back porches of input image and the horizontal and vertical active regions can also be measured. Firmware can adjust input image registers automatically by reading Auto Tune's registers in single or burst mode.

Auto Position

MTL005 provides Horizontal/Vertical back porch and active region values. Users can use these values to set input sample registers to aid in centering the screen automatically.

Phase Calibration

MTL005 provides Auto Calibration registers to measure the quality of current ADC's phase and frequency. The biggest Auto Calibration registers value means the right value of ADC's phase and frequency. MTL005 has two kinds of algorithms to calculate Auto Calibration's value. One is traditional Difference method, another is MYSON's proprietary method. It is suggested to use the latter one for better performance

Histogram

Histogram means the total number of input pixels below/above one threshold value, for individual R, G, B colors. This advanced function helps firmware to analyze ADC performance. Usually Firmware can use this information to measure ADC's noise margin, adjust its offset and gain, or even aid in the mode detection.

Min/Max Value

Min/Max value means minimum or maximum pixel value within the specified input active image region for each RGB channel. This information is usually used to adjust ADC's offset and gain.

Pixel Grab

Pixel Grab means users can grab a single input pixel at any one point. The position of the point can be programmed by users. This is another traditional method to measure ADC's phase and frequency.

3.2 Video Processor

General Description

MTL005 possesses a powerful and programmable video processor by providing the following functions: Scaling Up/Down, Gain Control, Brightness Control, Gamma Correction, Dithering Control, and Flip & Mirror. The block diagram of Video Processor is as follows:

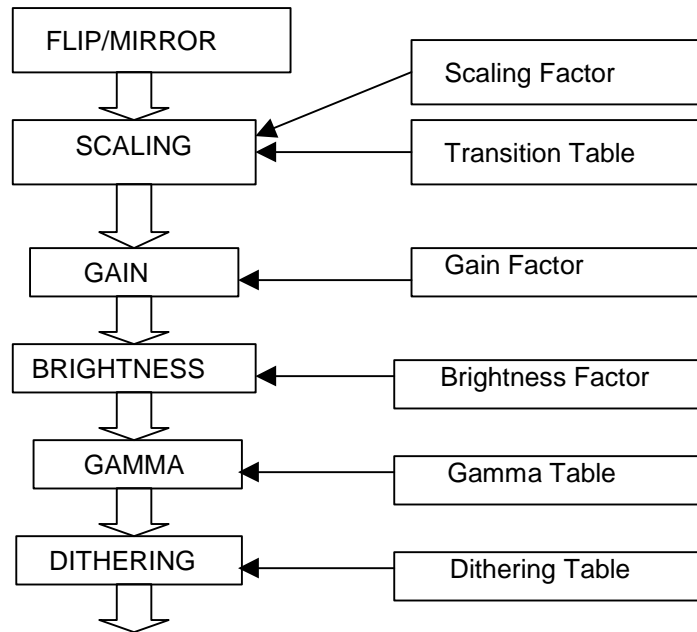

Fig. 3.2.1 Video Processor Block Diagram

3.2.1 Scaling

MTL005 provides scaling function up ranging from 1 to 32, and for both horizontal and vertical processing.

For scaling up, both horizontal and vertical processing, MTL005 provides four methods:

- Pass Mode:** Image will be passed through without considering any scaling factor.
- Duplicate Mode:** Image will be scaled up based on scaling factor. Every point of output image comes from the input. In this method, Output image will have the good contrast but may be non-uniformed.
- Bilinear Mode:** Image will be scaled up based on scaling factor. Every point of output image data will be filtered by bilinear filter. In this method, output image will have the good scaling quality but may be blurred.
- Interpolation Table Mode:** Image will be scaled up based on scaling factor. Every point of output image data will be filtered by user defined filter.

Fig. 3.2.2 Scaling filter

3.2.2 Gain/Brightness Control

MTL005 provides Gain and Brightness control to adjust the contrast and brightness of output color by programming gain and brightness coefficients. This adjustment is applied to RGB colors individually. Auto-white balance is possible by using this function.

3.2.3 Gamma Correction

Gamma Correction is used to compensate the non-linearity of LCD display panel. MTL005 contains a 8-bit Gamma table to fix this phenomenon.

3.2.4 Color Dithering

MTL005 supports true color (8 bits per color) or high color (6 bits per color) display.

In the latter case, users can turn on dithering function to avoid artificial contour due to truncation. For dithering, it supports two methods:

- Static dithering:** Dithering coefficient is fixed.
- Temporal dithering:** Dithering coefficient will change by time.

3.3 Output Processor

General Description

Output processor provides the interface for both LCD panel and OSD controller. output frame rate must be equal to input frame rate and output display time must be equal to input display time, because of no frame buffer.

3.3.1 Display Timing Generation

Output frame rate is equal to input frame and external frame buffer is not needed.

Fig. 3.3.1 Display Timing modes

3.3.2 OSD Overlay

MTL005 allows the integration of overlay data with the scaled output pixel stream. It provides a fully compatible OSD interface. Individual OSD clock, OSD HSYNC and OSD VSYNC are sent to external OSD device. MTL005 receives OSD Enable, OSD Red, OSD Green, and OSD Blue from external OSD device.

3.3.3 RGB Output Format

MTL005 output interface consists of two pixel ports, each containing Red, Green, and Blue color information with a resolution of 6/8 bits per color. These two ports are mapped to PORT1 and PORT2. The control signals for output port are display horizontal sync signal (DHSYNC), display vertical sync signal (DVSYNC) and display data enable signal (DDEN).

All the signals mentioned above are synchronous to the output clock. The output timing relative to the active edge of the output clock is programmable.

There are two RGB output formats:

Single Pixel Mode

It is designed to support TFT panels with single pixel input. Only PORT1 is active. The frequency of DCLK1 is equal to internal display clock.

Dual Pixel Mode

It is designed to support TFT panels with dual pixel input. PORT1 and PORT2 are used. The first pixel is at PORT1, and the second at PORT2.

Fig. 3.3.2 Display Data Timing

3.4 Host Interface

General Description

The main function of Host Interface is to provide the interface between MTL005 and external CPU by 2-wire I2C Bus. It can generate all the I/O decoded control timing to control all the registers in MTL005.

3.4.1 I2C Serial Bus

The I2C serial interface use 2 wires, SCK (clock) and SDA(data I/O). The SCK is used as the sampling clock and SDA is a bi-directional signal for data. The communication must be started with a valid START condition, concluded with STOP condition and acknowledged with ACK condition by receiver.

The I2C bus device address of MTL005 is 0111010x.

SCK, serial bus clock.

SDA, bi-directional serial bus data.

The START condition means a HIGH to LOW transition of SDA when SCK is high, the STOP condition means a LOW to HIGH transition of SDA when SCK is high. And data of SDA only can change during SCK is low. Ref. Fig.3.5.1.

Fig. 3.4.1 START, STOP ,and DATA definition

The I2C interface supports Random Write, Sequential Write, Current Address Read, Random Read and Sequential Read operations.

□ Random Write

For Random Write operation, it contains the slave address with R/W bit set to 0 and the word address which is comprised of eight bits and provides to access any one of 256 bytes in the selected memory range. Upon receipt of the word address, MTL005 responds with an Acknowledge, waits the data bits again responding an Acknowledge, and then the master generates a stop condition. Ref. Fig.3.5.2.

Fig. 3.4.2 Random Write

□ **Sequential Write**

The initial step of Sequential Write is the same as Random Write, after the receipt of each word data, MTL005 will respond with an Acknowledge and then internal address counter will increment by one for next data write. If the master would stop writing data, it generates stop condition. Ref. Fig. 3.5.3.

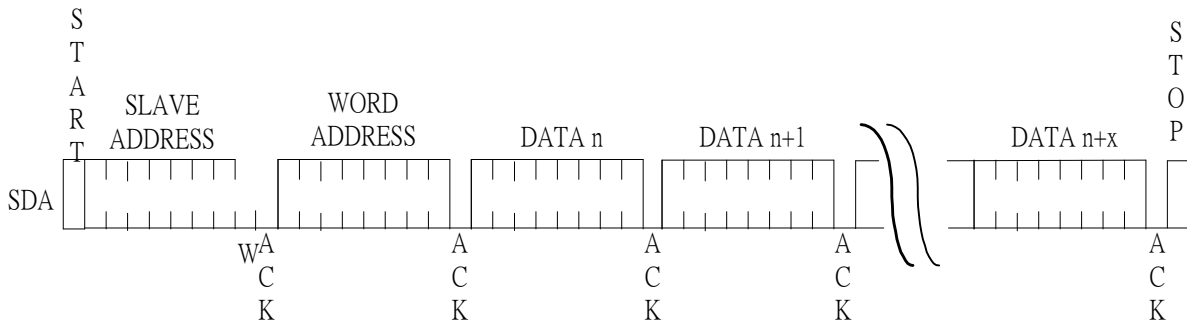

Fig. 3.4.3 Sequential Write

□ **Current Address Read**

MTL005 contains an address counter which maintains the last access address incremented by one. If the last access address is n, the read data should access from address n+1. Upon receipt of the slave address with R/W bit set to 1, MTL005 generates an Acknowledge and transmits eight bits data. After receiving data the master will generate a stop condition instead of an Acknowledge. Ref. Fig. 3.5.4.

Fig. 3.5.4 Current Address Read

□ **Random Read**

The operation of Random Read allows accessing any address. Before reading data operation, it must issue a “dummy write” operation—a start condition, a slave address with R/W bit set to 0, and word address for read. After responding an Acknowledge, MTL005 then transmits eight bits data right after the master generating the start condition and slave address with R/W bit set to 1. After completion of receiving data, the master will generate a stop condition instead of an Acknowledge. Ref. Fig 3.5.5.

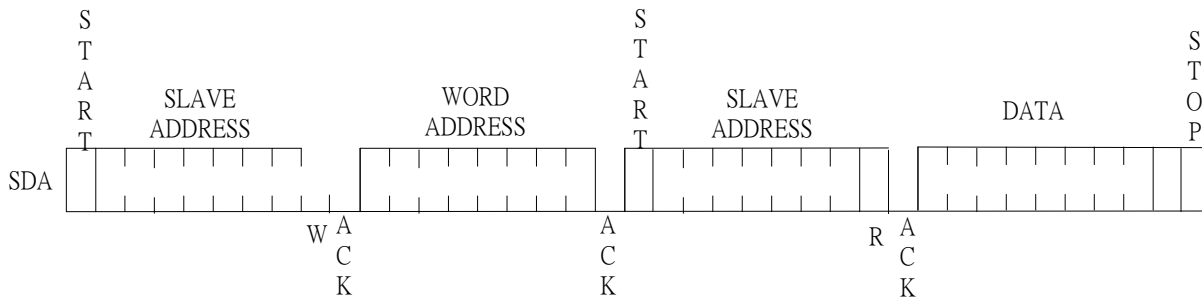

Fig. 3.4.5 Random Read

□ **Sequential Read**

The initial step can be as either Current Address Read or Random Read. The first read data is transmitted the same manner as other read methods. However, the master generates an Acknowledge indicating that it requires more data to read. MTL005 continues to output data for each Acknowledge received. The output data is sequential and the internal address counter increments by one for next read data. Ref. Fig. 3.5.6.

Fig. 3.4.6 Sequential Read

3.4.2 Interrupt

MTL005 supports one interrupt output signal (IRQ) which can be programmed to provide SYNC related or function status related interrupts to the system. Upon receiving the interrupt request, Firmware needs to first check the interrupt event by reading the Interrupt Flag Control registers (Reg. E8h and E9h) to decide what events are happening. After the operation is finished, Firmware needs to clear interrupt status by writing the same registers Reg. E8h and E9h. Furthermore, by using the Interrupt Flag Enable registers (Reg. EAh and EBh), each interrupt event can be masked.

3.4.3 Update Register Contents

I/O write operation to some consecutive register set can have the “Double Buffer” effect by setting the Reg. C1h/D4. Written data is first stored in an intermediate bank of latches and then transferred to the active register set by setting Reg. C1h/D1-0.

3.5 On-Chip PLL

General Description

The MTL005 needs two clock sources to drive synchronous circuits on chip. These clocks are generated from the internal Phase Lock Loop (PLL) circuits with reference to the oscillator clock which is applied to pin XI and XO by an external quartz crystal at 14.31818 MHz. First one is the same as to the oscillator clock at frequency (14.31818 MHz) to detect and measure graphic vertical and horizontal SYNC Frequency, Polarity as well as Presence. The second is the display clock for display controller on chip and output signals to LCD panel.

3.5.1 Reference Clock

It is the counting basis of counter values in SYNC Processor such as VS and HS period count registers; that is, the read back values from these registers must multiply the period of this clock to estimate VS and HS frequency. Incorporating with polarity and frequency information of VS and HS, it can show the input graphic image mode and pixel clock frequency.

3.5.2 Display Clock

This clock is the synchronous clock for LCD panel. According to the LCD panel resolution of applications, the display clock range is from 50 MHz to 200 MHz by means of choosing a set of appropriate values for M, N as well as R. The formula to calculate desired frequency of display clock is as follows:

$$f_{\text{mclk}} = f_{\text{osc}} \times (M+2) / (N+2) \times 1/R$$

Where

f_{mclk}	: the desired display clock
f_{osc}	: oscillator clock with 14.31818 MHz
M	: post-divider ratio
N	: pre-divider ratio
R	: optional divider ratio

D2-0 Reserved

Output Vertical Active Line Number - Low (Address AAh) (R/W)

It defines the low byte of Output Vertical Active Line Number -1, only used for getting the values of Reg. ACh and ADh.

D7-0 OVDE[7:0]

Output Vertical Active Line Number - High (Address ABh) (R/W)

It defines the high byte of Output Vertical Active Line Number -1, only used for getting the values of Reg. ACh and ADh.

D1-0 OVDE[9:8]

Output Horizontal Total Pixel Number - Low (Address ACh) (RO)

It states the low byte of Output Horizontal Total Pixel Number.

D7-0 OHTOT[7:0]

Output Horizontal Total Pixel Number - High (Address ADh) (RO)

It states the high byte of Output Horizontal Total Pixel Number.

D2-0 OHTOT[10:8]

Output Horizontal Total Residue Number - Low (Address AEh) (RO)

It states the low byte of Output Horizontal Total Pixel Residue Number.

D7-0 OHTOT_RES[7:0]

Output Horizontal Total Residue Number - High (Address AFh) (RO)

It states the high byte of Output Horizontal Total Pixel Residue Number.

Zoom Vertical Scale Ratio – Low (Address B4h) (R/W)

It defines the low byte of vertical scale ratio value for scale up.

D7-0 ZVSF[7:0]

Zoom Vertical Scale Ratio - High (Address B5h) (R/W)

It defines the high byte of vertical scale ratio value for scale up.

D7-0 ZVSF[15:8]

$ZVSF = \text{CEIL}[(\text{input_height} - 1) / (\text{output_height} - 1) * 2^{16}]$

Zoom Horizontal Scale Ratio - Low (Address B6h) (R/W)

It defines the low byte of horizontal scale ratio value for scale up.

D7-0 ZHSF[7:0]

Zoom Horizontal Scale Ratio - High (Address B7h) (R/W)

It defines the high byte of horizontal scale ratio value for scale up.

D7-0 ZHSF[15:8]
