

To all our customers

---

## **Regarding the change of names mentioned in the document, such as Mitsubishi Electric and Mitsubishi XX, to Renesas Technology Corp.**

---

The semiconductor operations of Hitachi and Mitsubishi Electric were transferred to Renesas Technology Corporation on April 1st 2003. These operations include microcomputer, logic, analog and discrete devices, and memory chips other than DRAMs (flash memory, SRAMs etc.) Accordingly, although Mitsubishi Electric, Mitsubishi Electric Corporation, Mitsubishi Semiconductors, and other Mitsubishi brand names are mentioned in the document, these names have in fact all been changed to Renesas Technology Corp. Thank you for your understanding. Except for our corporate trademark, logo and corporate statement, no changes whatsoever have been made to the contents of the document, and these changes do not constitute any alteration to the contents of the document itself.

Note : Mitsubishi Electric will continue the business operations of high frequency & optical devices and power devices.

### Keep safety first in your circuit designs!

- Mitsubishi Electric Corporation puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage. Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of non-flammable material or (iii) prevention against any malfunction or mishap.

### Notes regarding these materials

- These materials are intended as a reference to assist our customers in the selection of the Mitsubishi semiconductor product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Mitsubishi Electric Corporation or a third party.
- Mitsubishi Electric Corporation assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.
- All information contained in these materials, including product data, diagrams, charts, programs and algorithms represents information on products at the time of publication of these materials, and are subject to change by Mitsubishi Electric Corporation without notice due to product improvements or other reasons. It is therefore recommended that customers contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor for the latest product information before purchasing a product listed herein. The information described here may contain technical inaccuracies or typographical errors. Mitsubishi Electric Corporation assumes no responsibility for any damage, liability, or other loss rising from these inaccuracies or errors. Please also pay attention to information published by Mitsubishi Electric Corporation by various means, including the Mitsubishi Semiconductor home page (<http://www.mitsubishichips.com>).
- When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Mitsubishi Electric Corporation assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.
- Mitsubishi Electric Corporation semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
- The prior written approval of Mitsubishi Electric Corporation is necessary to reprint or reproduce in whole or in part these materials.
- If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination. Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.
- Please contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor for further details on these materials or the products contained therein.

REVISION HISTORY

38B7 GROUP USER'S MANUAL

Rev.	Date	Description	
		Page	Summary
1.0	07/07/00		First Edition
1.1	03/10/00	74 100	Mask options B to G are shaded to show that they cannot be specified. Note 4 added. Absolute maximum ratings VEE VCC-45 to VCC +0.3 VI VCC-45 to VCC +0.3 VO VCC-45 to VCC +0.3
1.2	11/01/01	1-2 1-2 1-7 1-8 1-75	Explanations of "DESCRIPTION" are partly eliminated. Oscillation frequency value of "FEATURES" are partly revised. Figure 3 is partly revised. Figure 4 is partly revised. "MASK OPTION OF PULL-DOWN RESISTOR" is eliminated.
1.3	01/29/03	1-21 1-41 1-100 2-91 2-164 2-164 2-164 2-177 2-177 2-177 3-10 3-15 3-21 3-23 3-23	Explanations of "■Note" are revised. "■Notes" is added. "Electric Characteristic Differences Between Mask ROM and Flash Memory Version MCUs" is added. Sub clause name and explanations of "(7) Setting procedure when serial I/O2 transmit interrupt is used" are revised. Clause name and explanations of "2.11.3 Each port state during "L" state of RESET pin" are revised. Table name of Table 2.11.1 is revised. Note of Table 2.11.1 is eliminated. Table 2.13.1 is partly revised. Explanations of "2.13.5 Serial I/O mode" are partly revised. Table 2.13.2 is partly revised. Figure 3.2.2 is revised. Sub clause name and explanations of "(1) Change of relevant register settings" are revised. Sub clause name and explanations of "(7) Setting procedure when serial I/O2 transmit interrupt is used" are revised. Clause name and explanations of "3.3.11 Each port state during "L" state of RESET pin" are revised. Table name of Table 3.3.3 is revised.

## Preface

This user's manual describes Mitsubishi's CMOS 8-bit microcomputers 38B7 Group.

After reading this manual, the user should have a thorough knowledge of the functions and features of the 38B7 Group, and should be able to fully utilize the product. The manual starts with specifications and ends with application examples.

For details of software, refer to the "740 Family Software Manual."

For details of development support tools, refer to the "Mitsubishi Microcomputer Development Support Tools" Homepage ([http://www.tool-spt.maec.co.jp/index\\_e.htm](http://www.tool-spt.maec.co.jp/index_e.htm)).

# BEFORE USING THIS USER'S MANUAL

This user's manual consists of the following three chapters. Refer to the chapter appropriate to your conditions, such as hardware design or software development.

## 1. Organization

### ● CHAPTER 1 HARDWARE

This chapter describes features of the microcomputer and operation of each peripheral function.

### ● CHAPTER 2 APPLICATION

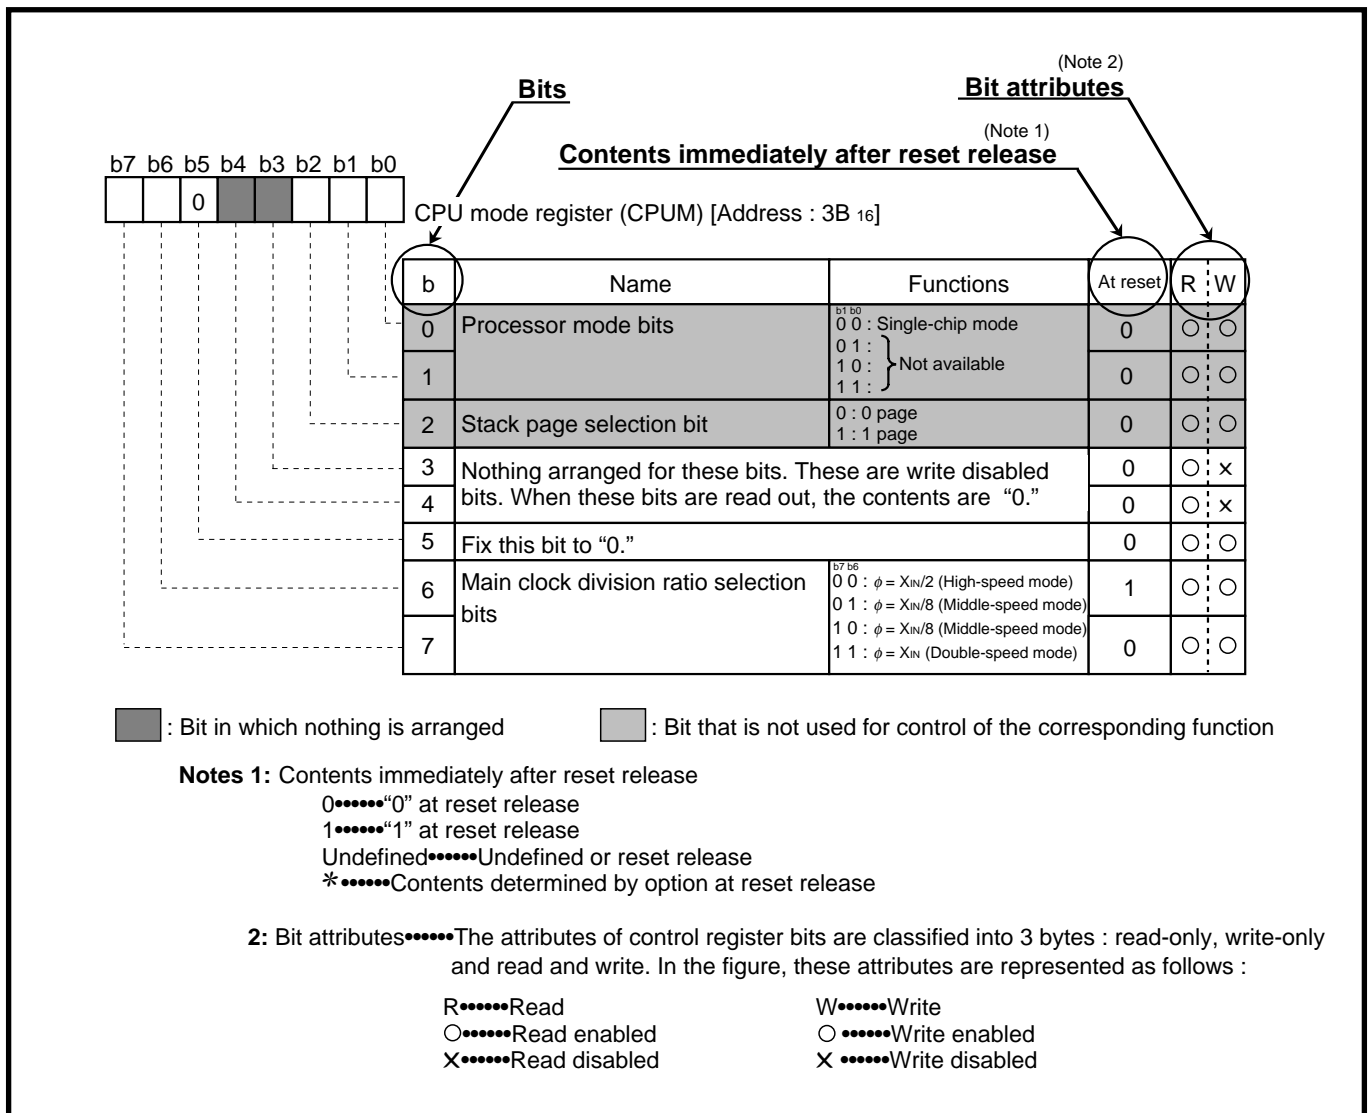

This chapter describes usage and application examples of peripheral functions, based mainly on setting examples of relevant registers.

### ● CHAPTER 3 APPENDIX

This chapter includes a list of registers, and necessary information for systems development using the microcomputer.

## 2. Structure of Register

The figure of each register structure describes its functions, contents at reset, and attributes as follows:

# Table of contents

## CHAPTER 1 HARDWARE

<b>DESCRIPTION</b> .....	<b>1-2</b>
<b>FEATURES</b> .....	<b>1-2</b>
<b>APPLICATION</b> .....	<b>1-2</b>
<b>PIN CONFIGURATION</b> .....	<b>1-3</b>
<b>FUNCTIONAL BLOCK</b> .....	<b>1-4</b>
<b>PIN DESCRIPTION</b> .....	<b>1-5</b>
<b>PART NUMBERING</b> .....	<b>1-7</b>
<b>GROUP EXPANSION</b> .....	<b>1-8</b>
Memory Type .....	1-8
Memory Size .....	1-8
Package .....	1-8
<b>FUNCTIONAL DESCRIPTION</b> .....	<b>1-9</b>
Central Processing Unit (CPU) .....	1-9
Memory .....	1-13
I/O Ports .....	1-15
Interrupts .....	1-21
Timers .....	1-24
Serial I/O .....	1-29
FLD Controller .....	1-44
A-D Converter .....	1-61
D-A Converter .....	1-62
PWM (Pulse Width Modulation) .....	1-63
Interrupt Interval Determination Function .....	1-66
Watchdog Timer .....	1-68
Buzzer Output Circuit .....	1-69
Reset Circuit .....	1-70
Clock Generating Circuit .....	1-72
Power Dissipation Calculating Method .....	1-75
Flash Memory Mode .....	1-78
<b>NOTES ON PROGRAMMING</b> .....	<b>1-99</b>
<b>NOTES ON USAGE</b> .....	<b>1-100</b>
<b>DATA REQUIRED FOR MASK ORDERS</b> .....	<b>1-100</b>

## CHAPTER 2 APPLICATION

<b>2.1 I/O port</b> .....	<b>2-2</b>
2.1.1 Memory assignment .....	2-2
2.1.2 Relevant registers .....	2-3
2.1.3 Terminate unused pins .....	2-8
2.1.4 Notes on I/O port .....	2-9
2.1.5 Termination of unused pins .....	2-10
<b>2.2 Timer</b> .....	<b>2-11</b>
2.2.1 Memory map .....	2-10
2.2.2 Relevant registers .....	2-12
2.2.3 Timer application examples .....	2-21

## Table of contents

---

<b>2.3 Serial I/O</b> .....	<b>2-37</b>
2.3.1 Memory map .....	2-37
2.3.2 Relevant registers .....	2-38
2.3.3 Serial I/O1 connection examples .....	2-50
2.3.4 Serial I/O1's modes .....	2-52
2.3.5 Serial I/O1 application examples .....	2-53
2.3.6 Serial I/O2 connection examples .....	2-59
2.3.7 Serial I/O2's modes .....	2-61
2.3.8 Serial I/O2 application examples .....	2-62
2.3.9 Serial I/O3 connection examples .....	2-81
2.3.10 Serial I/O3's modes .....	2-83
2.3.11 Serial I/O3 application examples .....	2-84
2.3.12 Notes on serial I/O1 .....	2-87
2.3.13 Notes on serial I/O2 .....	2-89
<b>2.4 FLD controller</b> .....	<b>2-92</b>
2.4.1 Memory assignment .....	2-92
2.4.2 Relevant registers .....	2-93
2.4.3 FLD controller application examples .....	2-101
2.4.4 Notes on FLD controller .....	2-132
<b>2.5 A-D converter</b> .....	<b>2-133</b>
2.5.1 Memory assignment .....	2-133
2.5.2 Relevant registers .....	2-134
2.5.3 A-D converter application examples .....	2-138
2.5.4 Notes on A-D converter .....	2-140
<b>2.6 D-A converter</b> .....	<b>2-141</b>
2.6.1 Memory assignment .....	2-141
2.6.2 Relevant registers .....	2-141
2.6.3 D-A converter application examples .....	2-143
2.6.4 Notes on D-A converter .....	2-144
<b>2.7 PWM</b> .....	<b>2-145</b>
2.7.1 Memory assignment .....	2-145
2.7.2 Relevant registers .....	2-145
2.7.3 PWM application example .....	2-147
2.7.4 Notes on PWM .....	2-148
<b>2.8 Interrupt interval determination function</b> .....	<b>2-149</b>
2.8.1 Memory assignment .....	2-149
2.8.2 Relevant registers .....	2-149
2.8.3 Interrupt interval determination function application examples .....	2-153
<b>2.9 Watchdog timer</b> .....	<b>2-157</b>
2.9.1 Memory assignment .....	2-157
2.9.2 Relevant register .....	2-157
2.9.3 Watchdog timer application examples .....	2-159
2.9.4 Notes on watchdog timer .....	2-160
<b>2.10 Buzzer output circuit</b> .....	<b>2-161</b>
2.10.1 Memory assignment .....	2-161
2.10.2 Relevant register .....	2-161
2.10.3 Buzzer output circuit application examples .....	2-162
<b>2.11 Reset circuit</b> .....	<b>2-163</b>
2.11.1 Connection example of reset IC .....	2-163
2.11.2 Notes on reset .....	2-164
2.11.3 Each port state during "L" state of RESET pin .....	2-164

<b>2.12 Clock generating circuit</b> .....	<b>2-165</b>
2.12.1 Relevant register .....	2-165
2.12.2 Clock generating circuit application examples .....	2-166
<b>2.13 Flash memory</b> .....	<b>2-174</b>
2.13.1 Overview .....	2-174
2.13.2 Memory map .....	2-174
2.13.3 Relevant registers .....	2-175
2.13.4 Parallel I/O mode .....	2-177
2.13.5 Serial I/O mode .....	2-177
2.13.6 CPU reprogramming mode .....	2-178
2.13.7 Flash memory mode application examples .....	2-179
2.13.8 Notes on CPU reprogramming mode .....	2-188
2.13.9 Notes on flash memory version .....	2-188

## CHAPTER 3 APPENDIX

<b>3.1 Electrical characteristics</b> .....	<b>3-2</b>
3.1.1 Absolute maximum ratings .....	3-2
3.1.2 Recommended operating conditions .....	3-2
3.1.3 Electrical characteristics .....	3-4
3.1.4 A-D converter characteristics .....	3-6
3.1.5 D-A converter characteristics .....	3-6
3.1.6 Timing requirements and switching characteristics .....	3-7
<b>3.2 Standard characteristics</b> .....	<b>3-10</b>
3.2.1 Power source current standard characteristics .....	3-10
3.2.2 Port standard characteristics .....	3-11
3.2.3 A-D conversion standard characteristics .....	3-14
<b>3.3 Notes on use</b> .....	<b>3-15</b>
3.3.1 Notes on interrupts .....	3-15
3.3.2 Notes on I/O port .....	3-16
3.3.3 Notes on serial I/O1 .....	3-17
3.3.4 Notes on serial I/O2 .....	3-19
3.3.5 Notes on FLD controller .....	3-21
3.3.6 Notes on A-D converter .....	3-22
3.3.7 Notes on D-A converter .....	3-22
3.3.8 Notes on PWM .....	3-22
3.3.9 Notes on watchdog timer .....	3-23
3.3.10 Notes on reset .....	3-23
3.3.11 Each pin state during “L” state of RESET pin .....	3-23
3.3.12 Notes on programming .....	3-24
3.3.13 Notes on CPU reprogramming mode .....	3-26
3.3.14 Notes on flash memory version .....	3-26
3.3.15 Termination of unused pins .....	3-27
<b>3.4 Countermeasures against noise</b> .....	<b>3-28</b>
3.4.1 Shortest wiring length .....	3-28
3.4.2 Connection of bypass capacitor across $V_{SS}$ line and $V_{CC}$ line .....	3-30
3.4.3 Wiring to analog input pins .....	3-31
3.4.4 Oscillator concerns .....	3-32
3.4.5 Setup for I/O ports .....	3-33
3.4.6 Providing of watchdog timer function by software .....	3-34

## Table of contents

## DESCRIPTION/FEATURES

### DESCRIPTION

The 38B7 group is the 8-bit microcomputer based on the 740 family core technology.

The 38B7 group has six 8-bit timers, one 16-bit timer, a fluorescent display automatic display circuit, 16-channel 10-bit A-D converter, a serial I/O with automatic transfer function, which are available for controlling musical instruments and household appliances.

### FEATURES

<Microcomputer mode>

- Basic machine-language instructions ..... 71
- The minimum instruction execution time ..... 0.48  $\mu$ s  
(at 4.2 MHz oscillation frequency)
- Memory size
  - ROM ..... 60K bytes
  - RAM ..... 2048 bytes
- Programmable input/output ports ..... 75
- High-breakdown-voltage output ports ..... 52
- Software pull-up resistors . (Ports P64 to P67, P7, P80 to P83, P9, PA, PB)
- Interrupts ..... 22 sources, 16 vectors
- Timers ..... 8-bit X 6, 16-bit X 1
- Serial I/O1 (Clock-synchronized) ..... 8-bit X 1  
(max. 256-byte automatic transfer function)
- Serial I/O2 (UART or Clock-synchronized) ..... 8-bit X 1
- Serial I/O3 (Clock-synchronized) ..... 8-bit X 1
- PWM ..... 14-bit X 1  
8-bit X 1 (also functions as timer 6)
- A-D converter ..... 10-bit X 16 channels
- D-A converter ..... 1 channel
- Fluorescent display function ..... Total 56 control pins
- Interrupt interval determination function ..... 1  
(Serviceable even in low-speed mode)
- Watchdog timer ..... 16-bit X 1
- Buzzer output ..... 1
- Two clock generating circuits
  - Main clock (XIN-XOUT) ..... Internal feedback resistor
  - Sub-clock (XCIN-XCOUT) ..... Without internal feedback resistor  
(connect to external ceramic resonator or quartz-crystal oscillator)
- Power source voltage
  - In high-speed mode ..... 4.0 to 5.5 V  
(at 4.2 MHz oscillation frequency and high-speed selected)
  - In middle-speed mode ..... 2.7 to 5.5 V (\*)  
(at 4.2 MHz oscillation frequency and middle-speed selected)
  - In low-speed mode ..... 2.7 to 5.5 V (\*)  
(at 32 kHz oscillation frequency)
  - (\*: 4.0 to 5.5 V for Flash memory version)
- Power dissipation
  - In high-speed mode ..... 35 mW  
(at 4.2 MHz oscillation frequency)
  - In low-speed mode ..... 60  $\mu$ W  
(at 32 kHz oscillation frequency, at 3 V power source voltage)
- Operating temperature range ..... -20 to 85 °C

<Flash memory mode>

- Supply voltage ..... VCC = 5 V  $\pm$  10 %
- Program/Erase voltage ..... VPP = 11.7 to 12.6 V
- Programming method ..... Programming in unit of byte
- Erasing method
  - Batch erasing ..... Parallel/Serial I/O mode
  - Block erasing ..... CPU reprogramming mode
- Program/Erase control by software command
- Number of times for programming/erasing ..... 100
- Operating temperature range (at programming/erasing)  
..... Normal temperature

### Notes

1. The flash memory version cannot be used for application embedded in the MCU card.
2. Power source voltage Vcc of the flash memory version is 4.0 to 5.5 V.

### APPLICATION

Musical instruments, VCR, household appliances, etc.

### PIN CONFIGURATION (TOP VIEW)

Package type: 100P6S-A

\*High-breakdown-voltage output port: Totaling 52

## GROUP EXPANSION

### GROUP EXPANSION

Mitsubishi plans to expand the 38B7 group as follows.

#### Memory Type

Support for Mask ROM and Flash memory versions.

#### Memory Size

Flash memory size ..... 60K bytes  
 Mask ROM size ..... 60K bytes  
 RAM size ..... 2048 bytes

#### Package

100P6S-A ..... 0.65 mm-pitch plastic molded QFP

**Note :** Products under development: the development schedule and specifications may be revised without notice.

**Fig. 4 Memory expansion plan**

Currently supported products are listed below.

**Table 3 List of supported products**

**As of Nov. 2001**

Product	ROM size (bytes) ROM size for User ( )	RAM size (bytes)	Package	Remarks
M38B79MFH-XXXXFP	61440	2048	100P6S-A	Mask ROM version
M38B79FFFP	(61310)			Flash memory version

### FUNCTIONAL DESCRIPTION Central Processing Unit (CPU)

The 38B7 group uses the standard 740 Family instruction set. Refer to the table of 740 Series addressing modes and machine instructions or the 740 Series Software Manual for details on the instruction set.

Machine-resident 740 Series instructions are as follows:

- The FST and SLW instructions cannot be used.
- The STP, WIT, MUL, and DIV instructions can be used.

#### [Accumulator (A)]

The accumulator is an 8-bit register. Data operations such as data transfer, etc., are executed mainly through the accumulator.

#### [Index Register X (X)]

The index register X is an 8-bit register. In the index addressing modes, the value of the OPERAND is added to the contents of register X and specifies the real address.

#### [Index Register Y (Y)]

The index register Y is an 8-bit register. In partial instruction, the value of the OPERAND is added to the contents of register Y and specifies the real address.

#### [Stack Pointer (S)]

The stack pointer is an 8-bit register used during subroutine calls and interrupts. This register indicates start address of stored area (stack) for storing registers during subroutine calls and interrupts. The low-order 8 bits of the stack address are determined by the contents of the stack pointer. The high-order 8 bits of the stack address are determined by the stack page selection bit. If the stack page selection bit is "0", the high-order 8 bits becomes "0016". If the stack page selection bit is "1", the high-order 8 bits becomes "0116".

The operations of pushing register contents onto the stack and popping them from the stack are shown in Figure 6.

Store registers other than those described in Figure 6 with program when the user needs them during interrupts or subroutine calls.

#### [Program Counter (PC)]

The program counter is a 16-bit counter consisting of two 8-bit registers PCH and PCL. It is used to indicate the address of the next instruction to be executed.

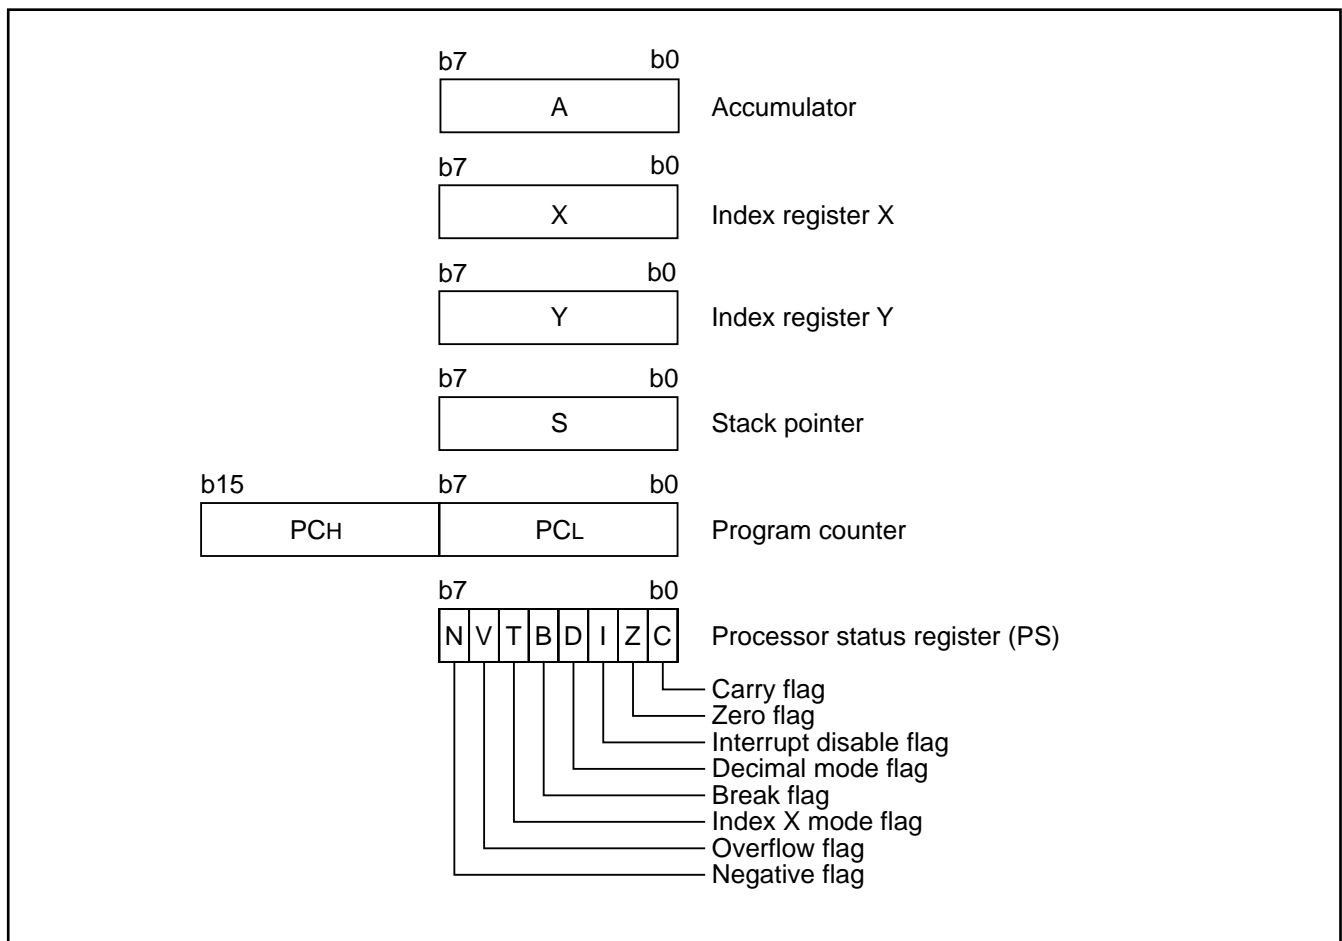

Fig. 5 740 Family CPU register structure

# HARDWARE

## FUNCTIONAL DESCRIPTION

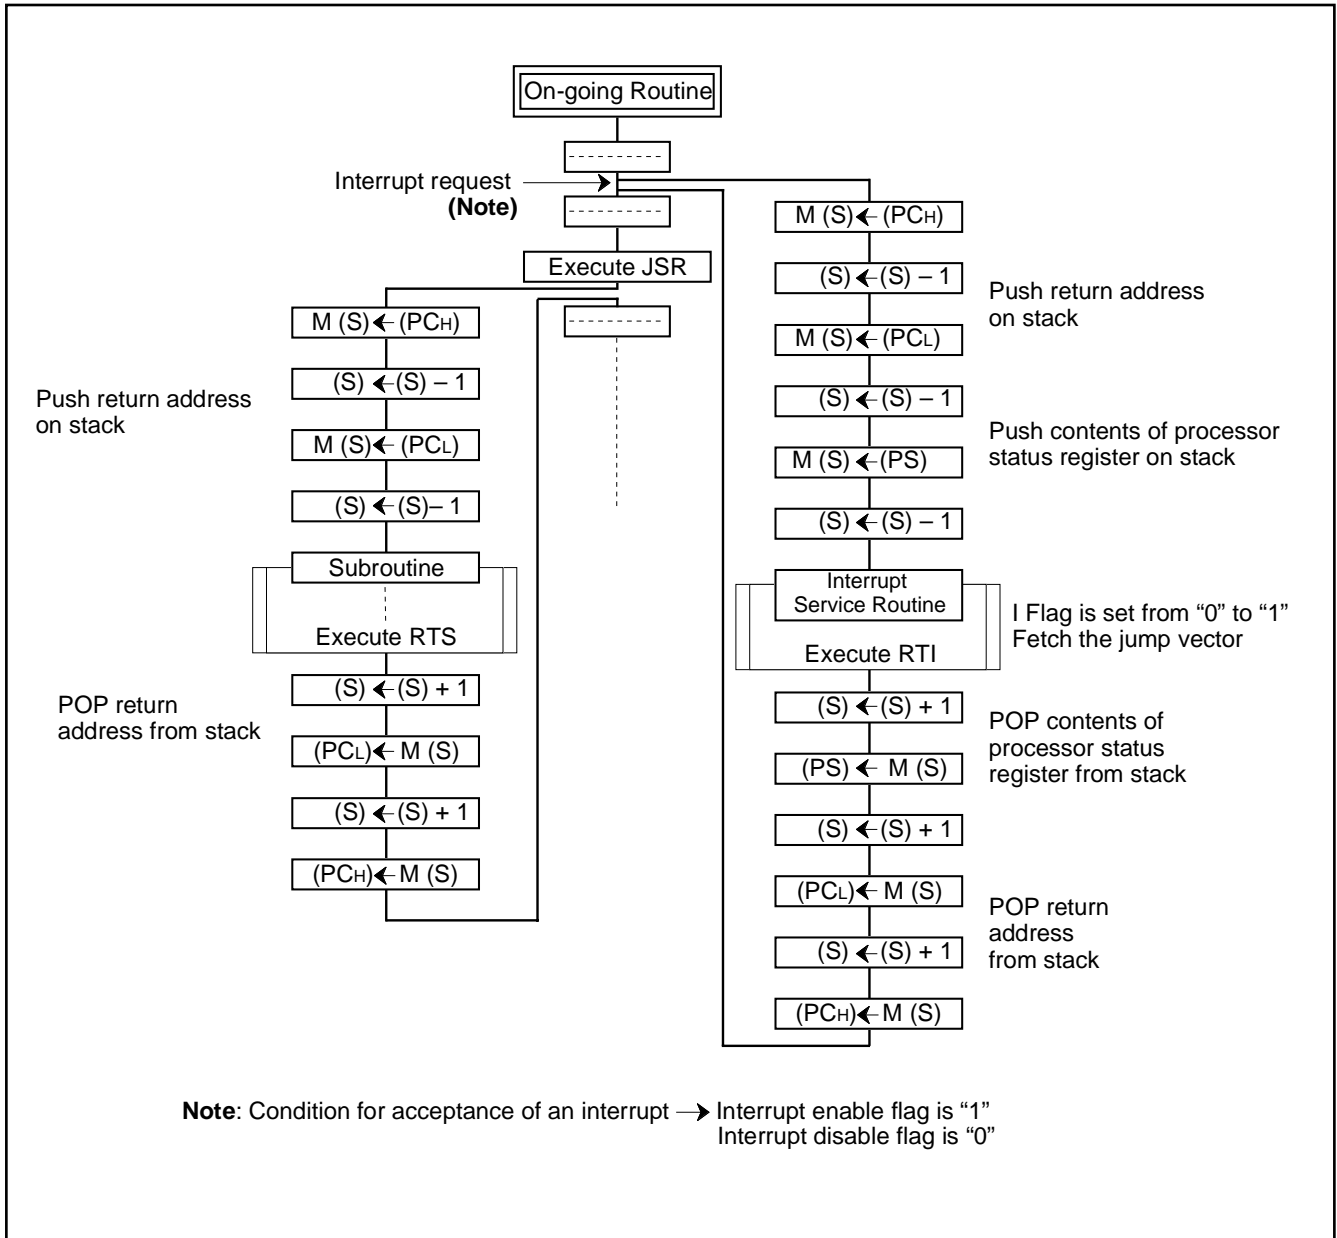

Fig. 6 Register push and pop at interrupt generation and subroutine call

Table 4 Push and pop instructions of accumulator or processor status register

	Push instruction to stack	Pop instruction from stack
Accumulator	PHA	PLA
Processor status register	PHP	PLP

### [Processor status register (PS)]

The processor status register is an 8-bit register consisting of 5 flags which indicate the status of the processor after an arithmetic operation and 3 flags which decide MCU operation. Branch operations can be performed by testing the Carry (C) flag, Zero (Z) flag, Overflow (V) flag, or the Negative (N) flag. In decimal mode, the Z, V, N flags are not valid.

•Bit 0: Carry flag (C)

The C flag contains a carry or borrow generated by the arithmetic logic unit (ALU) immediately after an arithmetic operation. It can also be changed by a shift or rotate instruction.

•Bit 1: Zero flag (Z)

The Z flag is set if the result of an immediate arithmetic operation or a data transfer is "0", and cleared if the result is anything other than "0".

•Bit 2: Interrupt disable flag (I)

The I flag disables all interrupts except for the interrupt generated by the BRK instruction.

Interrupts are disabled when the I flag is "1".

•Bit 3: Decimal mode flag (D)

The D flag determines whether additions and subtractions are executed in binary or decimal. Binary arithmetic is executed when this flag is "0"; decimal arithmetic is executed when it is "1".

Decimal correction is automatic in decimal mode. Only the ADC and SBC instructions can be used for decimal arithmetic.

•Bit 4: Break flag (B)

The B flag is used to indicate that the current interrupt was generated by the BRK instruction. The BRK flag in the processor status register is always "0". When the BRK instruction is used to generate an interrupt, the processor status register is pushed onto the stack with the break flag set to "1".

•Bit 5: Index X mode flag (T)

When the T flag is "0", arithmetic operations are performed between accumulator and memory. When the T flag is "1", direct arithmetic operations and direct data transfers are enabled between memory locations.

•Bit 6: Overflow flag (V)

The V flag is used during the addition or subtraction of one byte of signed data. It is set if the result exceeds +127 to -128. When the BIT instruction is executed, bit 6 of the memory location operated on by the BIT instruction is stored in the overflow flag.

•Bit 7: Negative flag (N)

The N flag is set if the result of an arithmetic operation or data transfer is negative. When the BIT instruction is executed, bit 7 of the memory location operated on by the BIT instruction is stored in the negative flag.

**Table 5 Set and clear instructions of each bit of processor status register**

	C flag	Z flag	I flag	D flag	B flag	T flag	V flag	N flag
Set instruction	SEC	–	SEI	SED	–	SET	–	–
Clear instruction	CLC	–	CLI	CLD	–	CLT	CLV	–

# HARDWARE

## FUNCTIONAL DESCRIPTION

### [CPU Mode Register (CPUM)] 003B16

The CPU mode register contains the stack page selection bit and the internal system clock selection bit etc.

The CPU mode register is allocated at address 003B16.

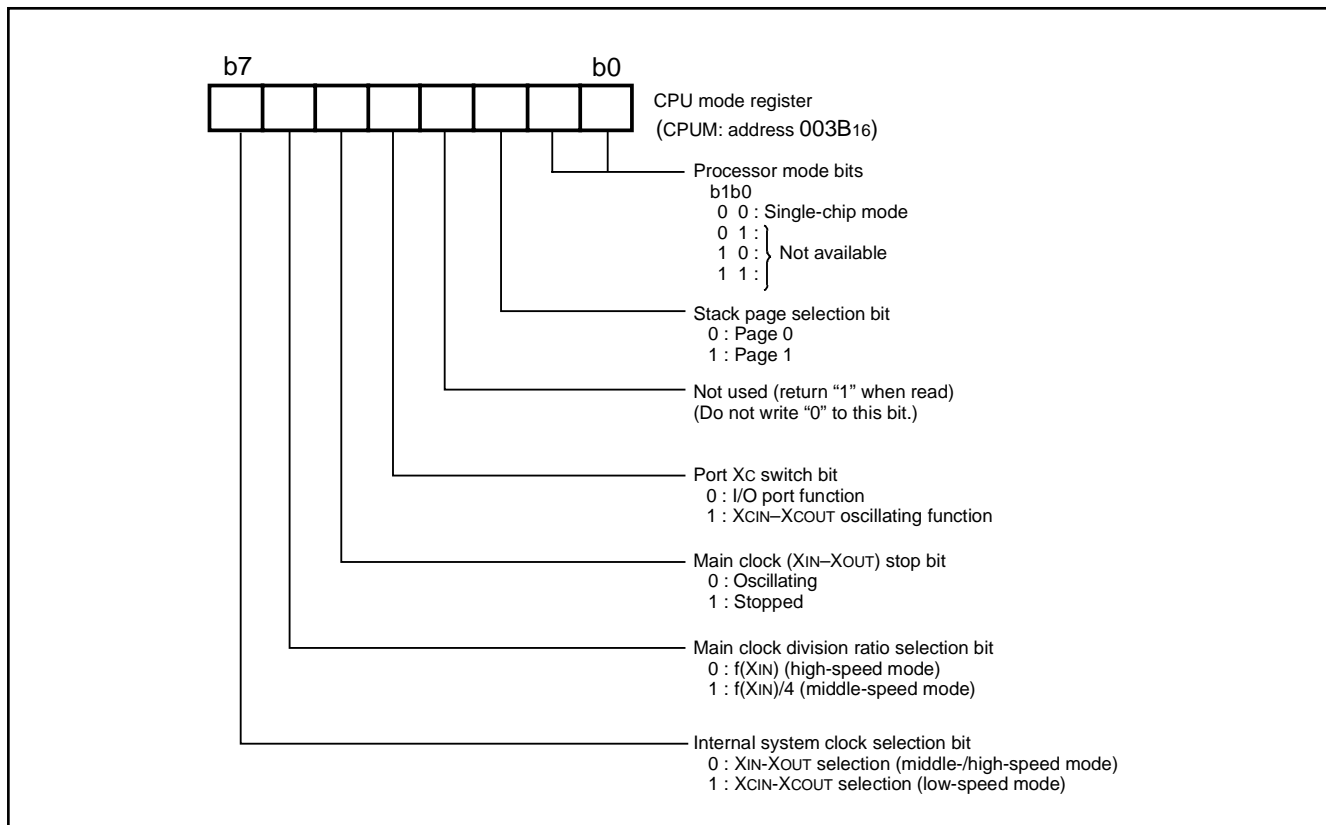

Fig. 7 Structure of CPU mode register

### MEMORY

#### Special Function Register (SFR) Area

The special function register (SFR) area contains control registers for I/O ports, timers and other functions.

#### RAM

RAM is used for data storage and for stack area of subroutine calls and interrupts.

#### ROM

The first 128 bytes and the last 2 bytes of ROM are reserved for device testing, and the other areas are user areas for storing programs.

#### Interrupt Vector Area

The interrupt vector area contains reset and interrupt vectors.

#### Zero Page

The zero page addressing mode can be used to specify memory and register addresses in the zero page area. Access to this area with only 2 bytes is possible in the zero page addressing mode.

#### Special Page

The special page addressing mode can be used to specify memory addresses in the special page area. Access to this area with only 2 bytes is possible in the special page addressing mode.

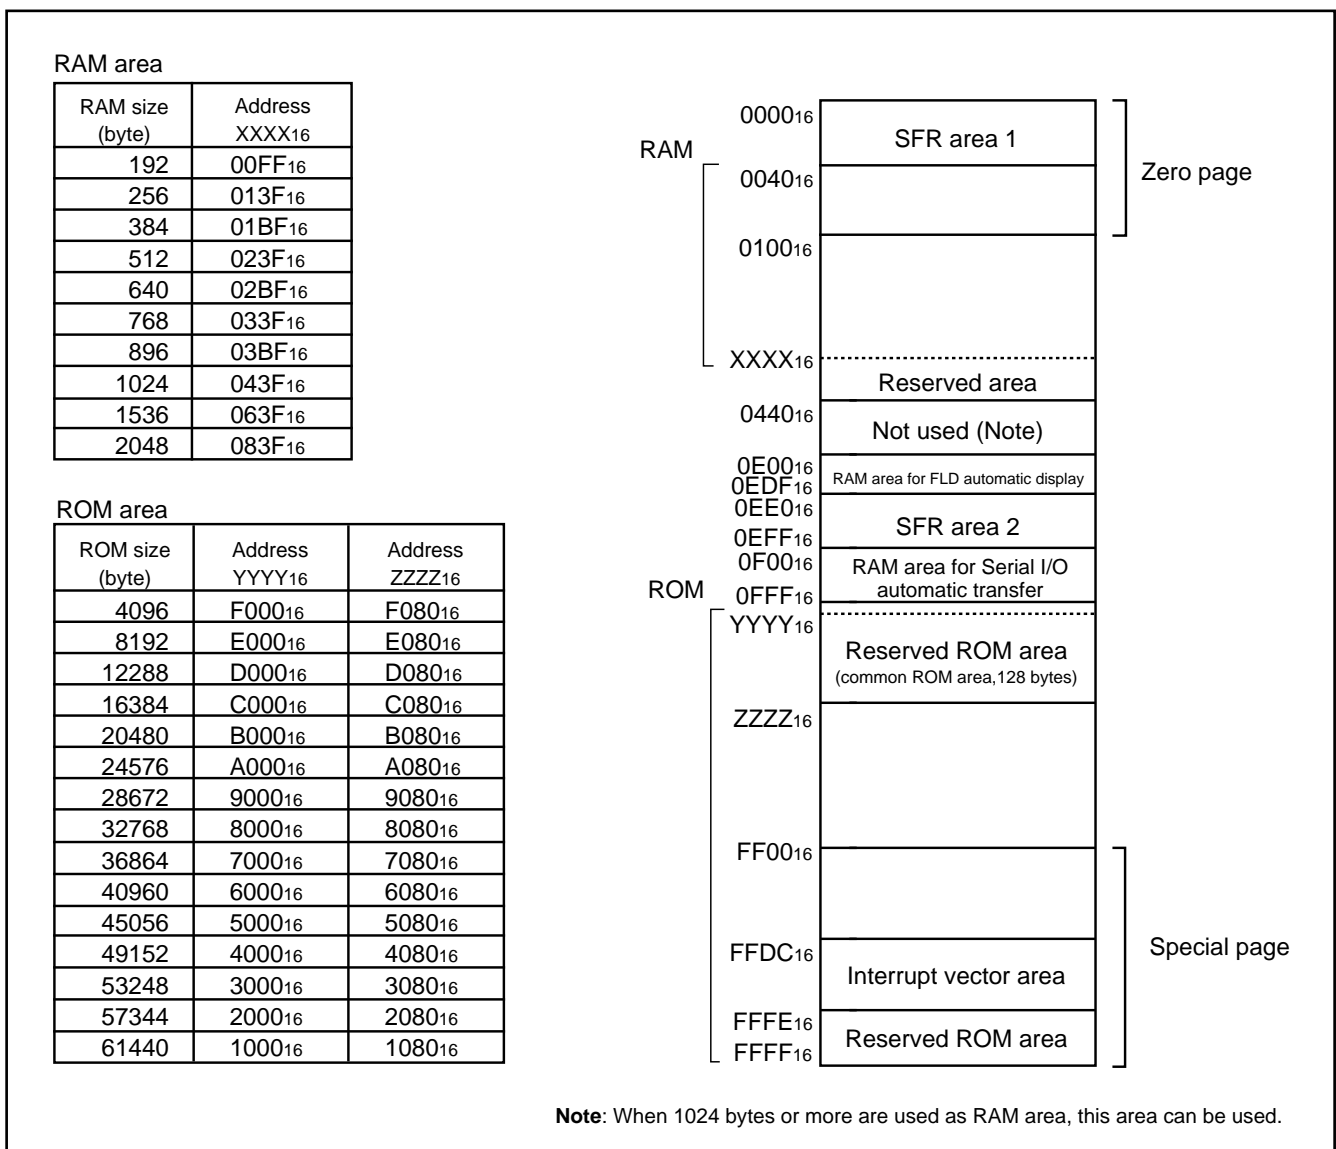

Fig. 8 Memory map diagram

Fig. 9 Memory map of special function register (SFR)

### I/O PORTS

#### [Direction Registers] PiD

The 38B7 group has 75 programmable I/O pins arranged in ten individual I/O ports (P1, P3, P4, P5, P6, P7, P8, P9, PA and PB). The I/O ports have direction registers which determine the input/output direction of each individual pin. Each bit in a direction register corresponds to one pin, and each pin can be set to be input port or output port. When “0” is written to the bit corresponding to a pin, that pin becomes an input pin. When “1” is written to that pin, that pin becomes an output pin. If data is read from a pin set to output, the value of the port output latch is read, not the value of the pin itself. Pins set to input (the bit corresponding to that pin must be set to “0”) are floating and the value of that pin can be read. If a pin set to input is written to, only the port output latch is written to and the pin remains floating.

#### [High-Breakdown-Voltage Output Ports]

The 38B7 group has seven ports with high-breakdown-voltage pins (ports P0 to P5 and P60–P63). The high-breakdown-voltage ports have P-channel open-drain output with  $V_{cc} - 45$  V of breakdown voltage. Each pin in ports P0 to P3 has an internal pull-down resistor connected to VEE. At reset, the P-channel output transistor of each port latch is turned off, so that it goes to VEE level (“L”) by the pull-down resistor.

Writing “1” (weak drivability) to bit 7 of the FLDC mode register (address 0EF416) shows the rising transition of the output transistors for reducing transient noise. At reset, bit 7 of the FLDC mode register is set to “0” (strong drivability).

#### [Pull-up Control Register] PULL

Ports P64–P67, P7, P80–P83, P9, PA and PB have built-in programmable pull-up resistors. The pull-up resistors are valid only in the case that the each control bit is set to “1” and the corresponding port direction registers are set to input mode.

## INTERRUPTS

Interrupts occur by twenty two sources: five external, sixteen internal, and one software.

### Interrupt Control

Each interrupt except the BRK instruction interrupt has both an interrupt request bit and an interrupt enable bit, and is controlled by the interrupt disable flag. An interrupt occurs if the corresponding interrupt request and enable bits are “1” and the interrupt disable flag is “0.” Interrupt enable bits can be set or cleared by software. Interrupt request bits can be cleared by software, but cannot be set by software. The BRK instruction interrupt and reset cannot be disabled with any flag or bit. The I flag disables all interrupts except the BRK instruction interrupt and reset. If several interrupts requests occur at the same time, the interrupt with highest priority is accepted first.

### Interrupt Operation

Upon acceptance of an interrupt the following operations are automatically performed:

1. The contents of the program counter and processor status register are automatically pushed onto the stack.
2. The interrupt disable flag is set and the corresponding interrupt request bit is cleared.
3. The interrupt jump destination address is read from the vector table into the program counter.

### Interrupt Source Selection

Any of the following interrupt sources can be selected by the interrupt source switch register (address 003916).

1. INT<sub>1</sub> or Serial I/O3
2. INT<sub>3</sub> or Serial I/O2 transmit
3. INT<sub>4</sub> or A-D conversion

### ■Note

When setting the followings, the interrupt request bit may be set to “1”.

- When switching external interrupt active edge  
Related register: Interrupt edge selection register (address 3A16)
- When switching interrupt sources of an interrupt vector address where two or more interrupt sources are allocated  
Related register: Interrupt source switch register (address 3916)

When not requiring the interrupt occurrence synchronized with these setting, take the following sequence.

- ① Set the corresponding interrupt enable bit to “0” (disabled).
- ② Set the interrupt edge select bit (active edge switch bit) or the interrupt (source) select/switch bit.
- ③ Set the corresponding interrupt request bit to “0” after 1 or more instructions have been executed.
- ④ Set the corresponding interrupt enable bit to “1” (enabled).

## FUNCTIONAL DESCRIPTION

### TIMERS

#### 8-Bit Timer

The 38B7 group has six built-in 8-bit timers : Timer 1, Timer 2, Timer 3, Timer 4, Timer 5, and Timer 6.

Each timer has the 8-bit timer latch. All timers are down-counters. When the timer reaches "00<sub>16</sub>", an underflow occurs with the next count pulse. Then the contents of the timer latch is reloaded into the timer and the timer continues down-counting. When a timer underflows, the interrupt request bit corresponding to that timer is set to "1".

The count can be stopped by setting the stop bit of each timer to "1". The internal system clock can be set to either the high-speed mode or low-speed mode with the CPU mode register. At the same time, the timer internal count source is switched to either f(X<sub>IN</sub>) or f(X<sub>CIN</sub>).

#### ●Timer 1, Timer 2

The count sources of timer 1 and timer 2 can be selected by setting the timer 12 mode register. A rectangular waveform of timer 1 underflow signal divided by 2 can be output from the P7<sub>5</sub>/T1<sub>OUT</sub> pin. The active edge of the external clock CNTR<sub>0</sub> can be switched with the bit 6 of the interrupt edge selection register.

At reset or when executing the STP instruction, all bits of the timer 12 mode register are cleared to "0", timer 1 is set to "FF<sub>16</sub>", and timer 2 is set to "01<sub>16</sub>".

#### ●Timer 3, Timer 4

The count sources of timer 3 and timer 4 can be selected by setting the timer 34 mode register. A rectangular waveform of timer 3 underflow signal divided by 2 can be output from the P7<sub>6</sub>/T3<sub>OUT</sub> pin. The active edge of the external clock CNTR<sub>1</sub> can be switched with the bit 7 of the interrupt edge selection register.

#### ●Timer 5, Timer 6

The count sources of timer 5 and timer 6 can be selected by setting the timer 56 mode register. A rectangular waveform of timer 6 underflow signal divided by 2 can be output from the P7<sub>4</sub>/PWM<sub>1</sub> pin.

#### ●Timer 6 PWM<sub>1</sub> Mode

Timer 6 can output a PWM rectangular waveform with "H" duty cycle  $n/(n+m)$  from the P7<sub>4</sub>/PWM<sub>1</sub> pin by setting the timer 56 mode register (refer to Figure 18). The n is the value set in timer 6 latch (address 0025<sub>16</sub>) and m is the value in the timer 6 PWM register (address 0027<sub>16</sub>). If n is "0," the PWM output is "L", if m is "0", the PWM output is "H" (n = 0 is prior than m = 0). In the PWM mode, interrupts occur at the rising edge of the PWM output.

Fig. 16 Structure of timer related registers

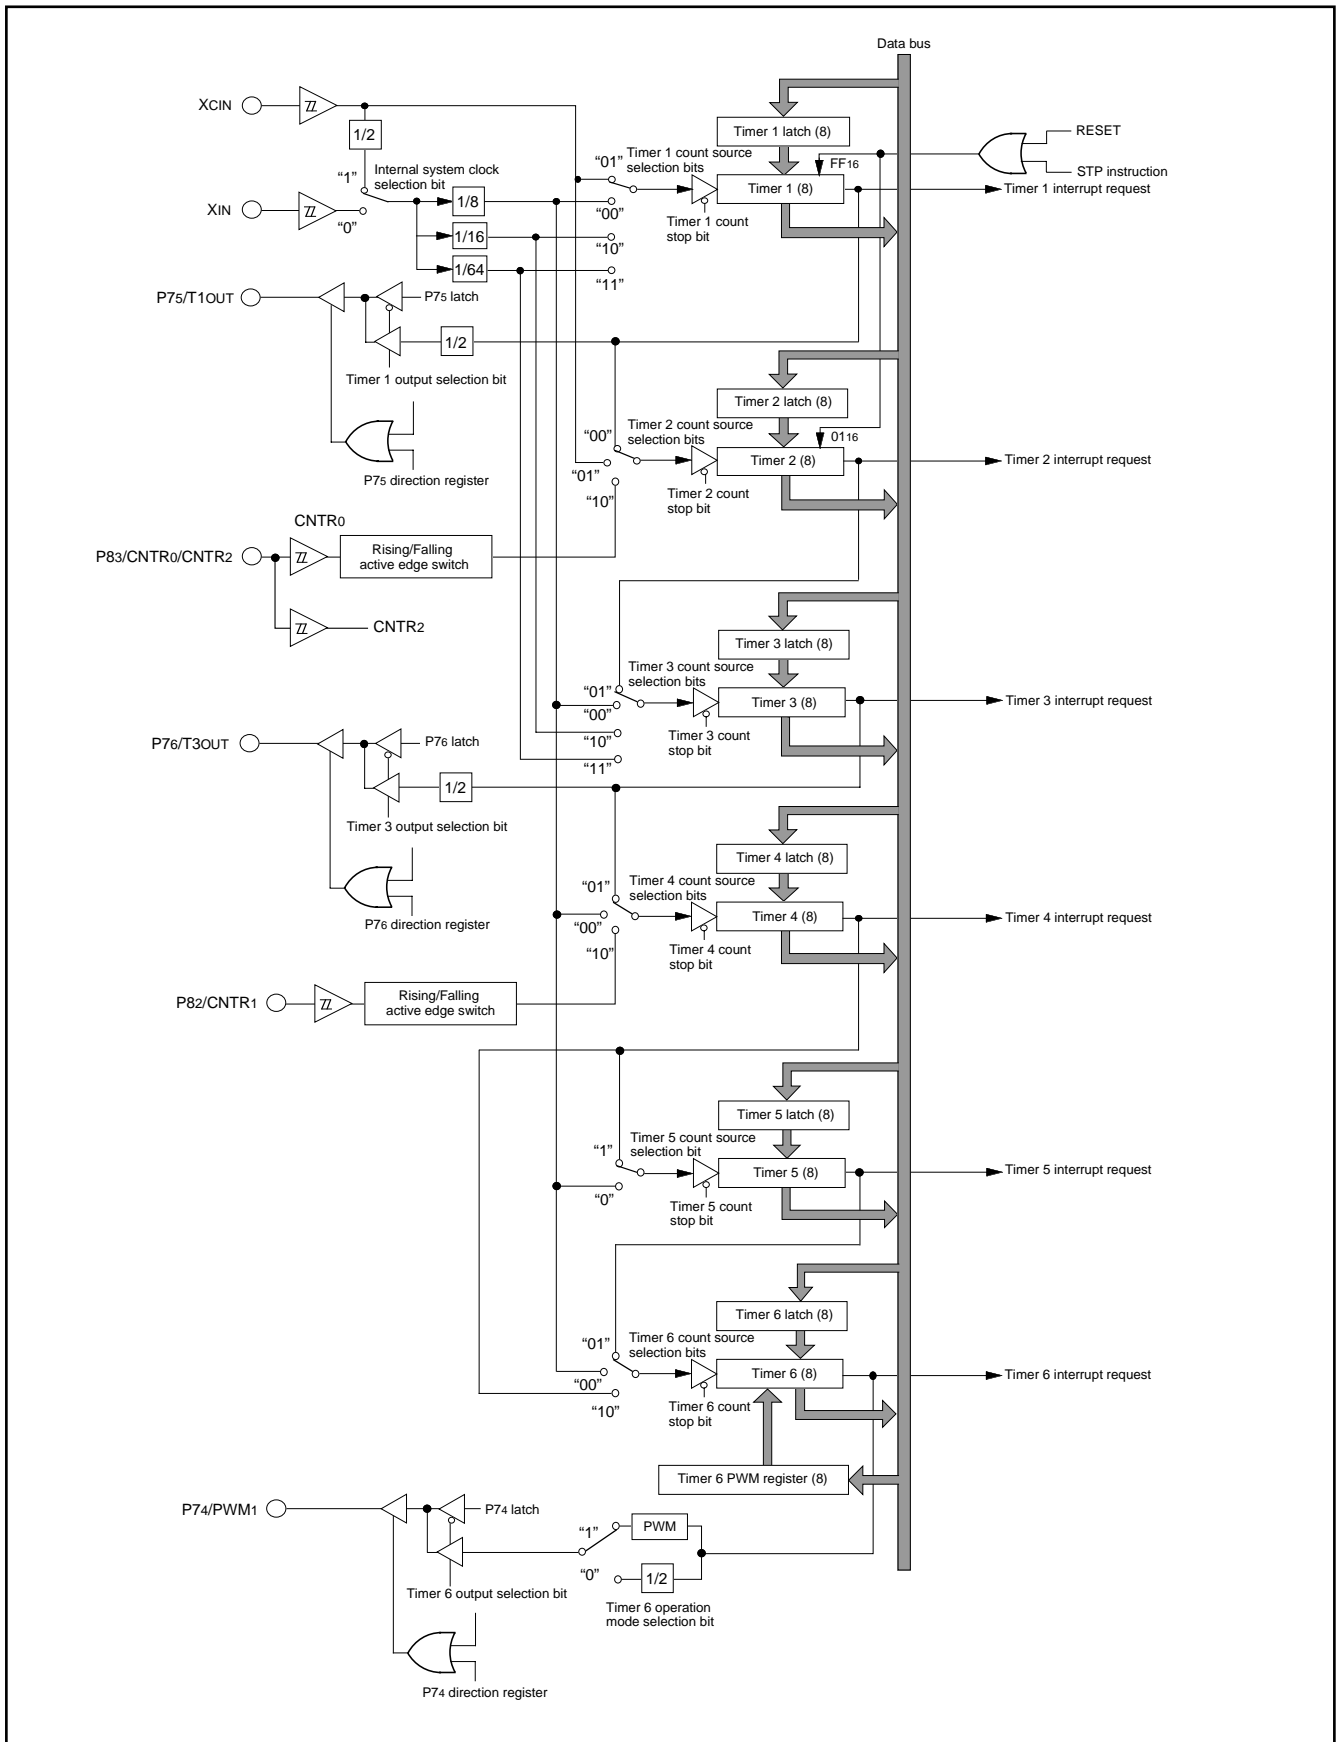

Fig. 17 Block diagram of timer

# HARDWARE

## FUNCTIONAL DESCRIPTION

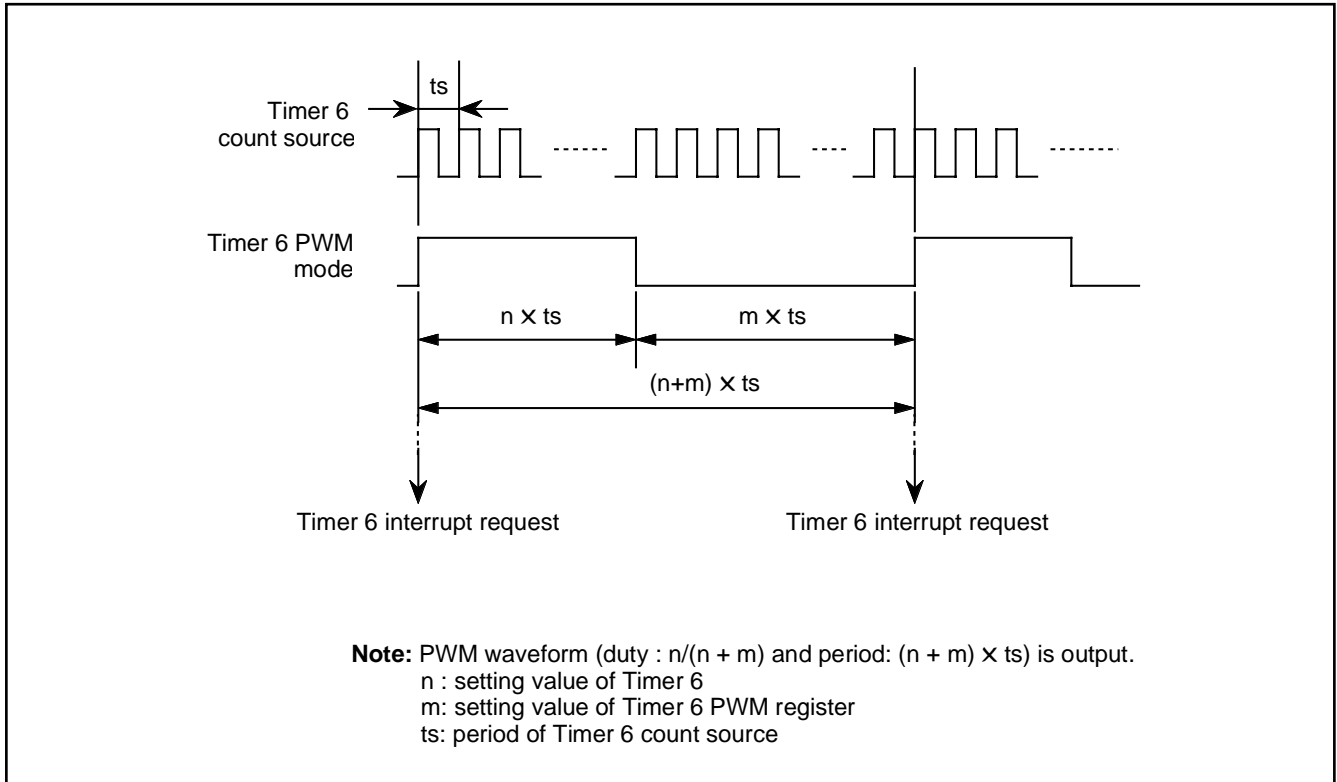

Fig. 18 Timing chart of timer 6 PWM1 mode

## 16-Bit Timer

Timer X is a 16-bit timer that can be selected in one of four modes by the Timer X mode registers 1, 2 and can be controlled for the timer X write and the real time port by setting the timer X mode registers.

Read and write operation on 16-bit timer must be performed for both high- and low-order bytes. When reading a 16-bit timer, read from the high-order byte first. When writing to 16-bit timer, write to the low-order byte first. The 16-bit timer cannot perform the correct operation when reading during write operation, or when writing during read operation.

### ●Timer X

Timer X is a down-counter. When the timer reaches "0000<sub>16</sub>", an underflow occurs with the next count pulse. Then the contents of the timer latch is reloaded into the timer and the timer continues down-counting. When a timer underflows, the interrupt request bit corresponding to that timer is set to "1".

#### (1) Timer mode

A count source can be selected by setting the Timer X count source selection bits (bits 1 and 2) of the Timer X mode register 1.

#### (2) Pulse output mode

Each time the timer underflows, a signal output from the CNTR<sub>2</sub> pin is inverted. Except for this, the operation in pulse output mode is the same as in timer mode. When using a timer in this mode, set the port shared with the CNTR<sub>2</sub> pin to output.

#### (3) Event counter mode

The timer counts signals input through the CNTR<sub>2</sub> pin. Except for this, the operation in event counter mode is the same as in timer mode. When using a timer in this mode, set the port shared with the CNTR<sub>2</sub> pin to input.

#### (4) Pulse width measurement mode

A count source can be selected by setting the Timer X count source selection bits (bits 1 and 2) of the Timer X mode register 1. When CNTR<sub>2</sub> active edge switch bit is "0", the timer counts while the input signal of the CNTR<sub>2</sub> pin is at "H". When it is "1", the timer counts while the input signal of the CNTR<sub>2</sub> pin is at "L". When using a timer in this mode, set the port shared with the CNTR<sub>2</sub> pin to input.

### ■ Note

#### •Timer X Write Control

If the timer X write control bit is "0", when the value is written in the address of timer X, the value is loaded in the timer X and the latch at the same time.

If the timer X write control bit is "1", when the value is written in the address of timer X, the value is loaded only in the latch. The value in the latch is loaded in timer X after timer X underflows.

When the value is written in latch only, unexpected value may be set in the high-order counter if the writing in high-order latch and the underflow of timer X are performed at the same timing.

#### •Real Time Port Control

While the real time port function is valid, data for the real time port are output from ports P9<sub>4</sub> and P9<sub>5</sub> each time the timer X underflows. (However, if the real time port control bit is changed from "0" to "1", data are output independent of the timer X.) When the data for the real time port is changed while the real time port function is valid, the changed data are output at the next underflow of timer X.

Before using this function, set the corresponding port direction registers to output mode.

### SERIAL I/O Serial I/O1

Serial I/O1 is used as the clock synchronous serial I/O and has an ordinary mode and an automatic transfer mode. In the automatic transfer mode, serial transfer is performed through the serial I/O automatic transfer RAM which has up to 256 bytes (addresses

0F00<sub>16</sub> to 0FFF<sub>16</sub>).

The PB1/SRDY1, PB2/SBUSY1, and PB3/SSTB1 pins each have a handshake I/O signal function and can select either "H" active or "L" active for active logic.

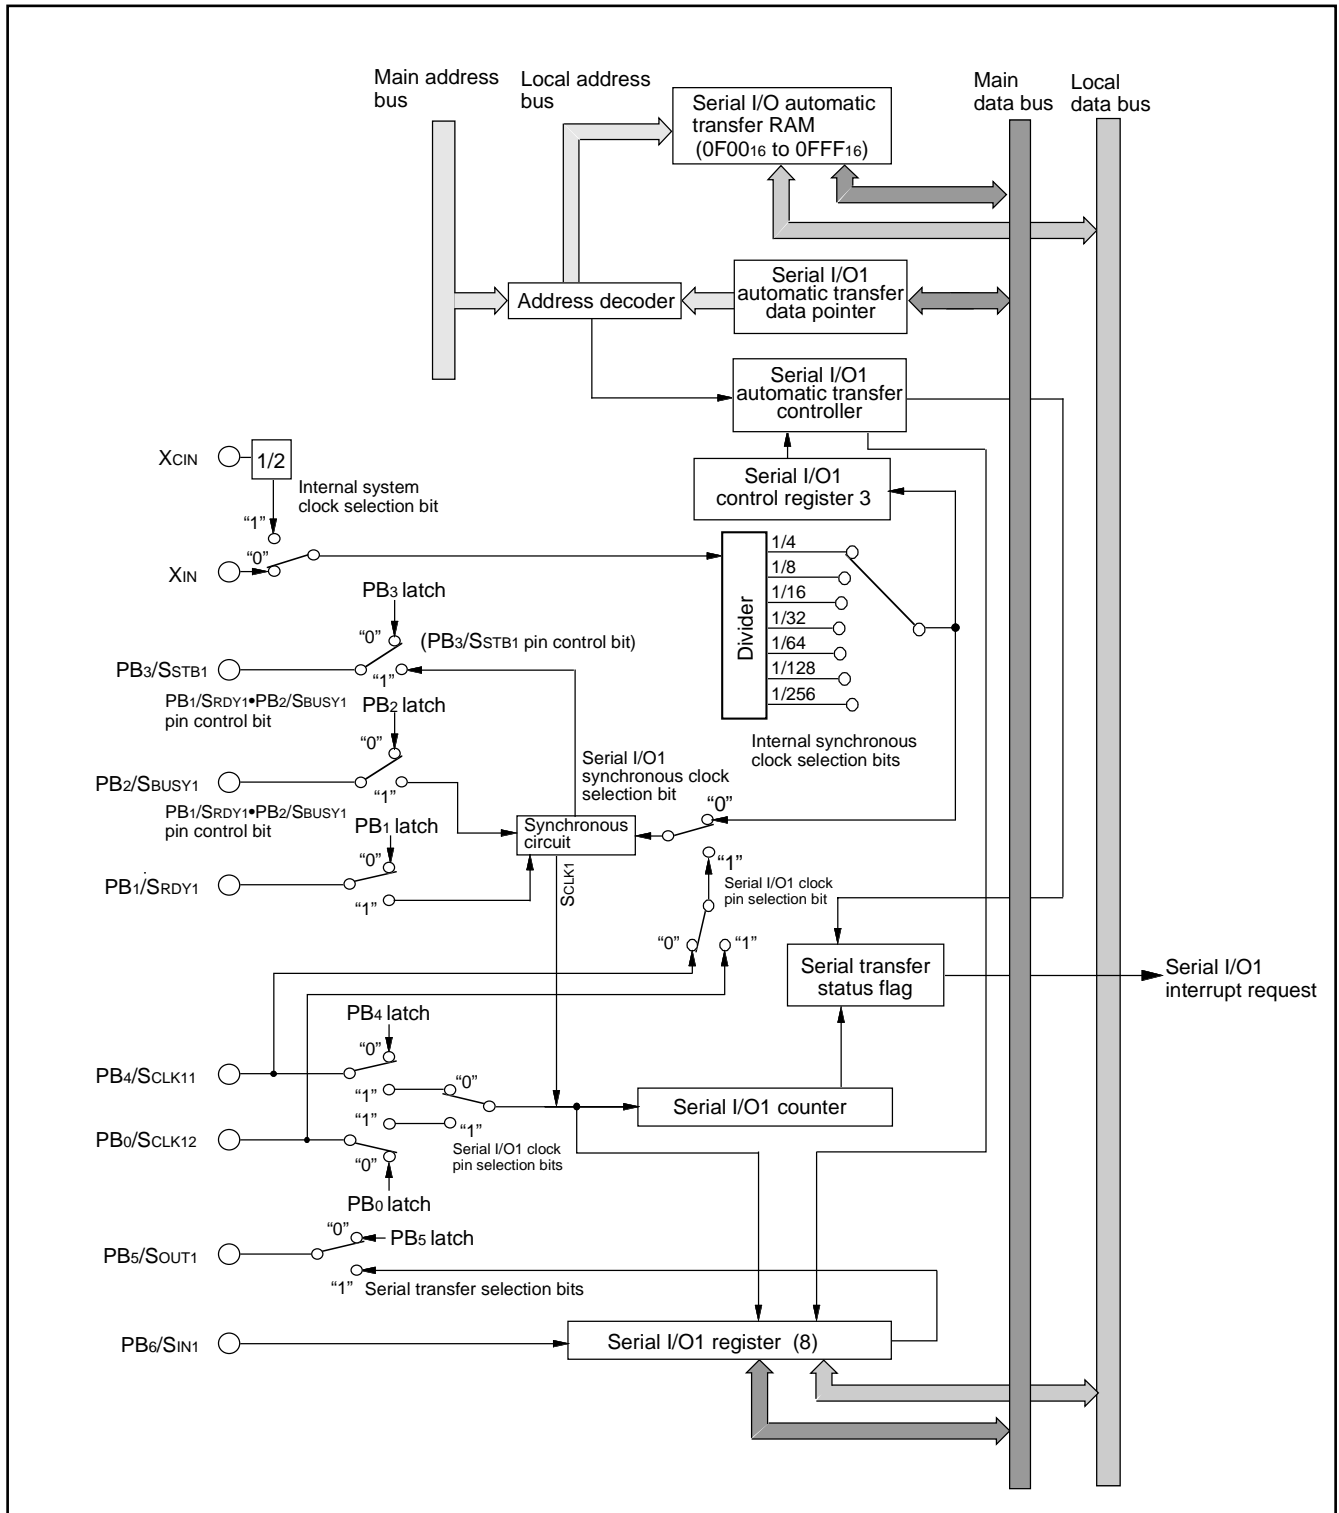

Fig. 21 Block diagram of serial I/O1

# HARDWARE

## FUNCTIONAL DESCRIPTION

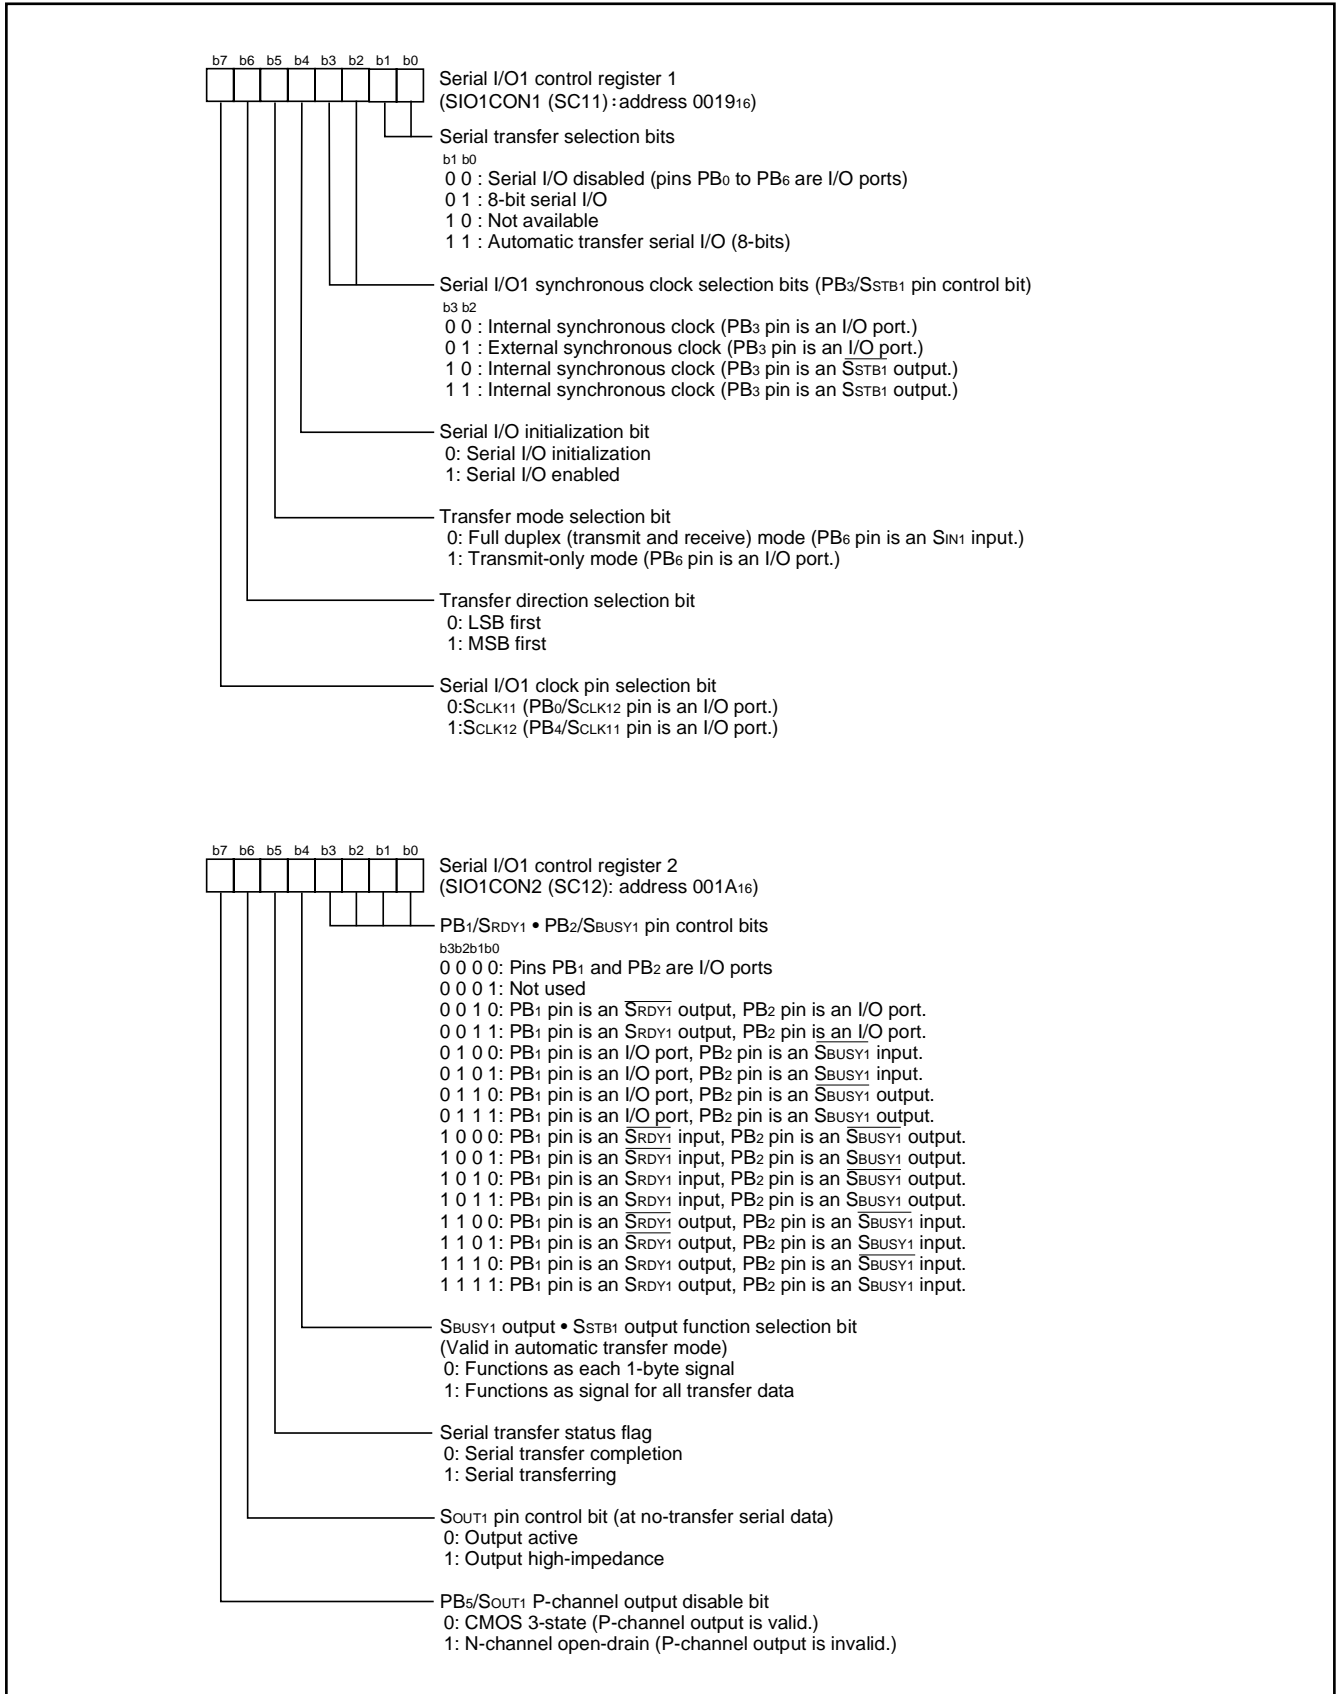

Fig. 22 Structure of serial I/O1 control registers 1, 2

### (1) Serial I/O1 operation

Either the internal synchronous clock or external synchronous clock can be selected by the serial I/O1 synchronous clock selection bits (b2 and b3 of address 001916) of serial I/O1 control register 1 as synchronous clock for serial transfer.

The internal synchronous clock has a built-in dedicated divider where 7 different clocks are selected by the internal synchronous clock selection bits (b5, b6 and b7 of address 001C16) of serial I/O1 control register 3.

The PB1/SRDY1, PB2/SBUSY1, and PB3/SSTB1 pins each select either I/O port or handshake I/O signal by the serial I/O1 synchronous clock selection bits (b2 and b3 of address 001916) of serial I/O1 control register 1 as well as the PB1/SRDY1 • PB2/SBUSY1 pin control bits (b0 to b3 of address 001A16) of serial I/O1 control register 2.

For the SOUT1 being used as an output pin, either CMOS output or N-channel open-drain output is selected by the PB5/SOUT1 P-channel output disable bit (b7 of address 001A16) of serial I/O1 control register 2.

Either output active or high-impedance can be selected as a SOUT1 pin state at serial non-transfer by the SOUT1 pin control bit (b6 of address 001A16) of serial I/O1 control register 2. However, when the external synchronous clock is selected, perform the following setup to put the SOUT1 pin into a high-impedance state:

When the SCLK1 input is "H" after completion of transfer, set the SOUT1 pin control bit to "1".

When the SCLK1 input goes to "L" after the start of the next serial transfer, the SOUT1 pin control bit is automatically reset to "0" and put into an output active state.

Regardless of whether the internal synchronous clock or external synchronous clock is selected, the full duplex mode and the transmit-only mode are available for serial transfer, one of which is selected by the transfer mode selection bit (b5 of address 001916) of serial I/O1 control register 1.

Either LSB first or MSB first is selected for the I/O sequence of the serial transfer bit strings by the transfer direction selection bit (b6 of address 001916) of serial I/O1 control register 1.

When using serial I/O1, first select either 8-bit serial I/O or automatic transfer serial I/O by the serial transfer selection bits (b0 and b1 of address 001916) of serial I/O1 control register 1, after completion of the above bit setup. Next, set the serial I/O initialization bit (b4 of address 001916) of serial I/O1 control register 1 to "1" (Serial I/O enable).

When stopping serial transfer while data is being transferred, regardless of whether the internal or external synchronous clock is selected, reset the serial I/O initialization bit (b4) to "0".

Fig. 23 Structure of serial I/O1 control register 3

# HARDWARE

## FUNCTIONAL DESCRIPTION

### (2) 8-bit serial I/O mode

Address 001B16 is assigned to the serial I/O1 register.

When the internal synchronous clock is selected, a serial transfer of the 8-bit serial I/O is started by a write signal to the serial I/O1 register (address 001B16).

The serial transfer status flag (b5 of address 001A16) of serial I/O1 control register 2 indicates the shift register status of serial I/O1, and is set to "1" by writing into the serial I/O1 register, which becomes a transfer start trigger and reset to "0" after completion of 8-bit transfer. At the same time, a serial I/O1 interrupt request occurs.

When the external synchronous clock is selected, the contents of the serial I/O1 register are continuously shifted while transfer clocks are input to SCLK1. Therefore, the clock needs to be controlled externally.

### (3) Automatic transfer serial I/O mode

The serial I/O1 automatic transfer controller controls the write and read operations of the serial I/O1 register, so that the function of address 001B16 is used as a transfer counter (1-byte unit).

When performing serial transfer through the serial I/O automatic transfer RAM (addresses 0F0016 to 0FFF16), it is necessary to set the serial I/O1 automatic transfer data pointer (address 001816) beforehand.

Input the low-order 8 bits of the first data store address to be serially transferred to the automatic transfer data pointer set bits.

When the internal synchronous clock is selected, the transfer interval for each 1-byte data can be set by the automatic transfer interval set bits (b0 to b4 of address 001C16) of serial I/O1 control register 3 in the following cases:

1. When using no handshake signal
2. When using the SRDY1 output, SBUSY1 output, and SSTB1 output of the handshake signal independently
3. When using a combination of SRDY1 output and SSTB1 output or a combination of SBUSY1 output and SSTB1 output of the handshake signal.

It is possible to select one of 32 different values, namely 2 to 33 cycles of the transfer clock, as a setting value.

When using the SBUSY1 output and selecting the SBUSY1 output • SSTB1 output function selection bit (b4 of address 001A16) of serial

I/O1 control register 2 as the signal for all transfer data, provided that the automatic transfer interval setting is valid, a transfer interval is placed before the start of transmission/reception of the first data and after the end of transmission/reception of the last data.

For SSTB1 output, regardless of the contents of the SBUSY1 output • SSTB1 output function selection bit (b4), the transfer interval for each 1-byte data is longer than the set value by 2 cycles.

Furthermore, when using a combination of SBUSY1 output and SSTB1 output as a signal for all transfer data, the transfer interval after the end of transmission/reception of the last data is longer than the set value by 2 cycles.

When the external synchronous clock is selected, automatic transfer interval setting is disabled.

After completion of the above bit setup, if the internal synchronous clock is selected, automatic serial transfer is started by writing the value of "number of transfer bytes – 1" into the transfer counter (address 001B16).

When the external synchronous clock is selected, write the value of "number of transfer bytes – 1" into the transfer counter and keep an internal system clock interval of 5 cycles or more. After that, input transfer clock to SCLK1.

As a transfer interval for each 1-byte data transfer, keep an internal system clock interval of 5 cycles or more from the clock rise time of the last bit.

Regardless of whether the internal or external synchronous clock is selected, the automatic transfer data pointer and the transfer counter are decremented after each 1-byte data is received and then written into the automatic transfer RAM. The serial transfer status flag (b5 of address 001A16) is set to "1" by writing data into the transfer counter. Writing data becomes a transfer start trigger, and the serial transfer status flag is reset to "0" after the last data is written into the automatic transfer RAM. At the same time, a serial I/O1 interrupt request occurs.

The values written in the automatic transfer data pointer set bits (b0 to b7 of address 001816) and the automatic transfer interval set bits (b0 to b4 of address 001C16) are held in the latch.

When data is written into the transfer counter, the values latched in the automatic transfer data pointer set bits (b0 to b7) and the automatic transfer interval set bits (b0 to b4) are transferred to the decrement counter.

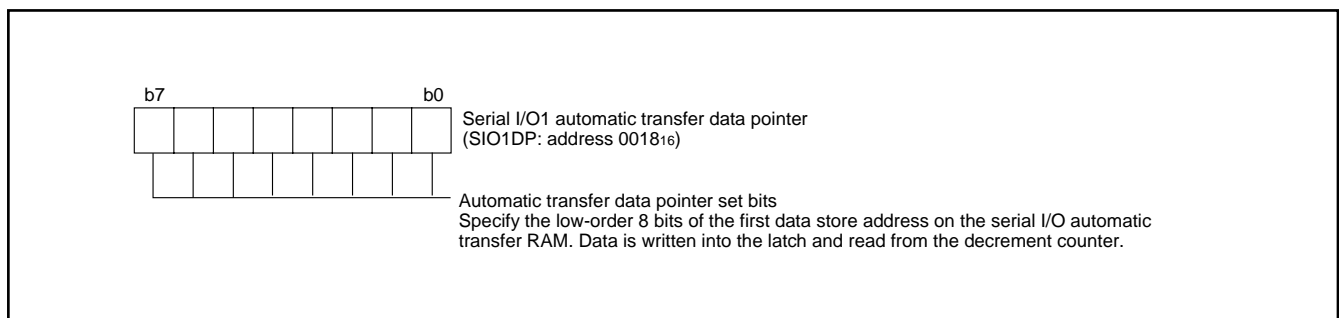

Fig. 24 Structure of serial I/O1 automatic transfer data pointer

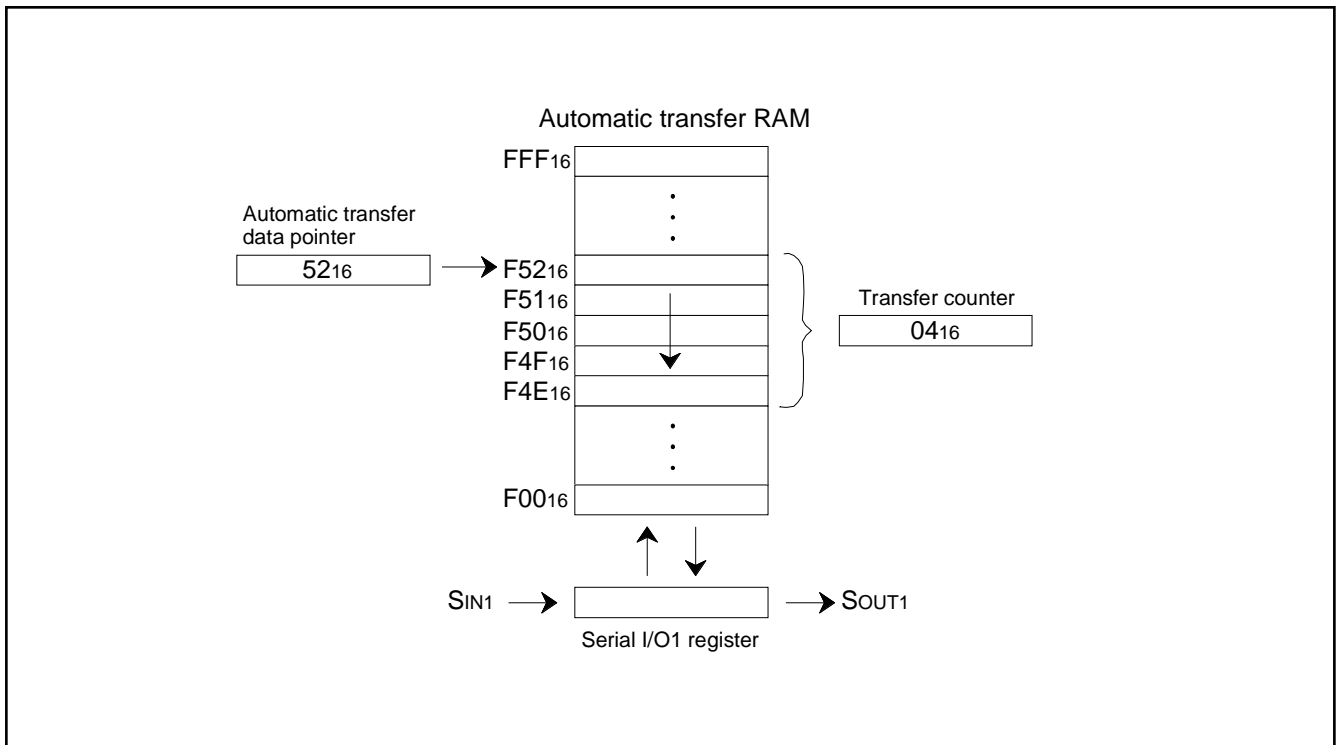

Fig. 25 Automatic transfer serial I/O operation

# HARDWARE

## FUNCTIONAL DESCRIPTION

### (4) Handshake signal

#### 1. S<sub>STB1</sub> output signal

The S<sub>STB1</sub> output is a signal to inform an end of transmission/reception to the serial transfer destination. The S<sub>STB1</sub> output signal can be used only when the internal synchronous clock is selected. In the initial status, namely, in the status in which the serial I/O initialization bit (b4) is reset to "0", the S<sub>STB1</sub> output goes to "L", or the  $\overline{S_{STB1}}$  output goes to "H".

At the end of transmit/receive operation, when the data of the serial I/O1 register is all output from S<sub>OUT1</sub>, pulses are output in the period of 1 cycle of the transfer clock so as to cause the S<sub>STB1</sub> output to go "H" or the  $\overline{S_{STB1}}$  output to go "L". After that, each pulse is returned to the initial status in which S<sub>STB1</sub> output goes to "L" or the  $\overline{S_{STB1}}$  output goes to "H".

Furthermore, after 1 cycle, the serial transfer status flag (b5) is reset to "0".

In the automatic transfer serial I/O mode, whether the S<sub>STB1</sub> output is to be active at an end of each 1-byte data or after completion of transfer of all data can be selected by the S<sub>BUSY1</sub> output • S<sub>STB1</sub> output function selection bit (b4 of address 001A16) of serial I/O1 control register 2.

#### 2. S<sub>BUSY1</sub> input signal

The S<sub>BUSY1</sub> input is a signal which receives a request for a stop of transmission/reception from the serial transfer destination.

When the internal synchronous clock is selected, input an "H" level signal into the S<sub>BUSY1</sub> input and an "L" level signal into the  $\overline{S_{BUSY1}}$  input in the initial status in which transfer is stopped.

When starting a transmit/receive operation, input an "L" level signal into the S<sub>BUSY1</sub> input and an "H" level signal into the  $\overline{S_{BUSY1}}$  input in the period of 1.5 cycles or more of the transfer clock. Then, transfer clocks are output from the S<sub>CLK1</sub> output.

When an "H" level signal is input into the S<sub>BUSY1</sub> input and an "L" level signal into the  $\overline{S_{BUSY1}}$  input after a transmit/receive operation is started, this transmit/receive operation are not stopped immediately and the transfer clocks from the S<sub>CLK1</sub> output is not stopped until the specified number of bits are transmitted and received.

The handshake unit of the 8-bit serial I/O is 8 bits and that of the automatic transfer serial I/O is 8 bits.

When the external synchronous clock is selected, input an "H" level signal into the S<sub>BUSY1</sub> input and an "L" level signal into the  $\overline{S_{BUSY1}}$  input in the initial status in which transfer is stopped. At this time, the transfer clocks to be input in S<sub>CLK1</sub> become invalid.

During serial transfer, the transfer clocks to be input in S<sub>CLK1</sub> become valid, enabling a transmit/receive operation, while an "L" level signal is input into the S<sub>BUSY1</sub> input and an "H" level signal is input into the  $\overline{S_{BUSY1}}$  input.

When changing the input values in the S<sub>BUSY1</sub> input and the  $\overline{S_{BUSY1}}$  input at these operations, change them when the S<sub>CLK1</sub> input is in a high state.

When the high impedance of the S<sub>OUT1</sub> output is selected by the S<sub>OUT1</sub> pin control bit (b6), the S<sub>OUT1</sub> output becomes active, enabling serial transfer by inputting a transfer clock to S<sub>CLK1</sub>, while an "L" level signal is input into the S<sub>BUSY1</sub> input and an "H" level signal is input into the  $\overline{S_{BUSY1}}$  input.

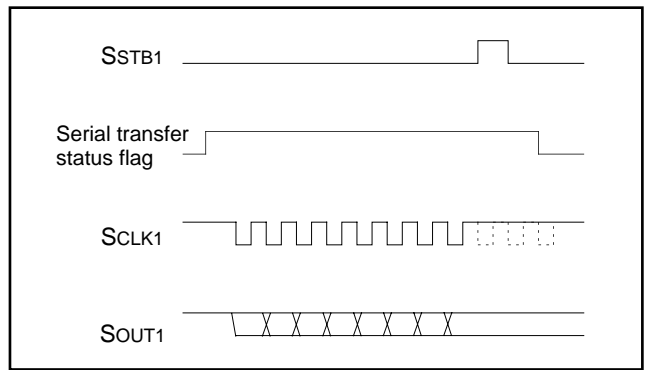

Fig. 26 S<sub>STB1</sub> output operation

Fig. 27 S<sub>BUSY1</sub> input operation (internal synchronous clock)

Fig. 28 S<sub>BUSY1</sub> input operation (external synchronous clock)

#### 3. S<sub>BUSY1</sub> output signal

The S<sub>BUSY1</sub> output is a signal which requests a stop of transmission/reception to the serial transfer destination. In the automatic transfer serial I/O mode, regardless of the internal or external synchronous clock, whether the S<sub>BUSY1</sub> output is to be active at transfer of each 1-byte data or during transfer of all data can be selected by the S<sub>BUSY1</sub> output • S<sub>STB1</sub> output function selection bit (b4).

In the initial status, the status in which the serial I/O initialization bit (b4) is reset to "0", the S<sub>BUSY1</sub> output goes to "H" and the  $\overline{S_{BUSY1}}$  output goes to "L".

When the internal synchronous clock is selected, in the 8-bit serial I/O mode and the automatic transfer serial I/O mode (SBUSY1 output function outputs in 1-byte units), the SBUSY1 output goes to "L" and the  $\overline{\text{SBUSY1}}$  output goes to "H" before 0.5 cycle (transfer clock) of the timing at which the transfer clock from the SCLK1 output goes to "L" at a start of transmit/receive operation.

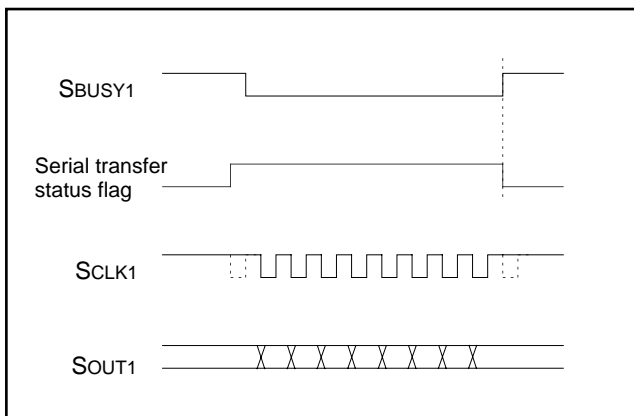

In the automatic transfer serial I/O mode (the SBUSY1 output function outputs all transfer data), the SBUSY1 output goes to "L" and the  $\overline{\text{SBUSY1}}$  output goes to "H" when the first transmit data is written into the serial I/O1 register (address 001B16).

When the external synchronous clock is selected, the SBUSY1 output goes to "L" and the  $\overline{\text{SBUSY1}}$  output goes to "H" when transmit

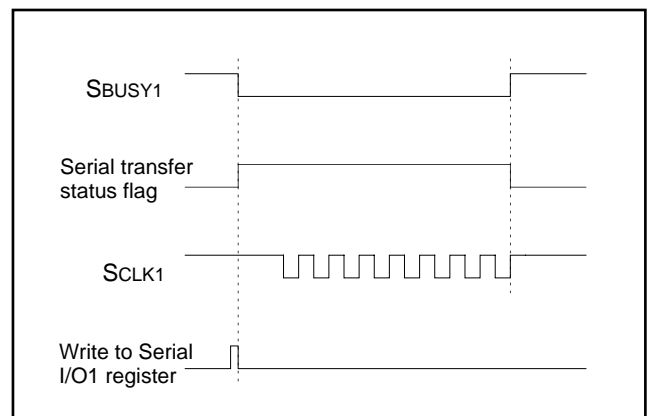

data is written into the serial I/O1 register to start a transmit operation, regardless of the serial I/O transfer mode.

At termination of transmit/receive operation, the SBUSY1 output returns to "H" and the  $\overline{\text{SBUSY1}}$  output returns to "L", the initial status, when the serial transfer status flag is set to "0", regardless of whether the internal or external synchronous clock is selected.

Furthermore, in the automatic transfer serial I/O mode (SBUSY1 output function outputs in 1-byte units), the SBUSY1 output goes to "H" and the  $\overline{\text{SBUSY1}}$  output goes to "L" each time 1-byte of receive data is written into the automatic transfer RAM.

# HARDWARE

## FUNCTIONAL DESCRIPTION

### 4. SRDY1 output signal

The SRDY1 output is a transmit/receive enable signal which informs the serial transfer destination that transmit/receive is ready. In the initial status, when the serial I/O initialization bit (b4) is reset to "0", the SRDY1 output goes to "L" and the  $\overline{\text{SRDY1}}$  output goes to "H". After transmitted data is stored in the serial I/O1 register (address 001B16) and a transmit/receive operation becomes ready, the SRDY1 output goes to "H" and the  $\overline{\text{SRDY1}}$  output goes to "L". When a transmit/receive operation is started and the transfer clock goes to "L", the SRDY1 output goes to "L" and the  $\overline{\text{SRDY1}}$  output goes to "H".

### 5. SRDY1 input signal

The SRDY1 input signal becomes valid only when the SRDY1 input and the SBUSY1 output are used. The SRDY1 input is a signal for receiving a transmit/receive ready completion signal from the serial transfer destination.

When the internal synchronous clock is selected, input a low level signal into the SRDY1 input and a high level signal into the  $\overline{\text{SRDY1}}$  input in the initial status in which the transfer is stopped.

When an "H" level signal is input into the SRDY1 input and an "L" level signal is input into the  $\overline{\text{SRDY1}}$  input for a period of 1.5 cycles or more of transfer clock, transfer clocks are output from the SCLK1 output and a transmit/receive operation is started.

After the transmit/receive operation is started and an "L" level signal is input into the SRDY1 input and an "H" level signal into the  $\overline{\text{SRDY1}}$  input, this operation cannot be immediately stopped.

After the specified number of bits are transmitted and received, the transfer clocks from the SCLK1 output is stopped. The handshake unit of the 8-bit serial I/O and that of the automatic transfer serial I/O are of 8 bits.

When the external synchronous clock is selected, the SRDY1 input becomes one of the triggers to output the SBUSY1 signal.

To start a transmit/receive operation (SBUSY1 output: "L", SBUSY1 output: "H"), input an "H" level signal into the SRDY1 input and an "L" level signal into the  $\overline{\text{SRDY1}}$  input, and also write transmit data into the serial I/O1 register.

Fig. 32 SRDY1 output operation

Fig. 33 SRDY1 input operation (internal synchronous clock)

Fig. 34 Handshake operation at serial I/O1 mutual connecting (1)

Fig. 35 Handshake operation at serial I/O1 mutual connecting (2)

### (2) Asynchronous serial I/O (UART) mode

The asynchronous serial I/O (UART) mode can be selected by clearing the serial I/O2 mode selection bit (b6) of the serial I/O2 control register (address 001D<sub>16</sub>) to "0". Eight serial data transfer formats can be selected and the transfer formats used by the transmitter and receiver must be identical.

The transmit and receive shift registers each have a buffer (the two buffers have the same address in memory). Since the shift register cannot be written to or read from directly, transmit data is written to the transmit buffer, and receive data is read from the receive buffer. The transmit buffer can also hold the next data to be transmitted, and the receive buffer can receive 2-byte data continuously.

Fig. 38 Block diagram of UART serial I/O2

Fig. 39 Operation of UART serial I/O2 function

# HARDWARE

## FUNCTIONAL DESCRIPTION

---

### **[Serial I/O2 Control Register] SIO2CON (001D16)**

The serial I/O2 control register contains eight control bits for serial I/O2 functions.

### **[UART Control Register] UARTCON (003816)**

This is a 7 bit register containing four control bits, of which four bits are valid when UART is selected, and of which three bits are always valid.

Data format of serial data receive/transfer and the output structure of the P65/TxD pin and others are set by this register.

### **[Serial I/O2 Status Register] SIO2STS (001E16)**

The read-only serial I/O2 status register consists of seven flags (b0 to b6) which indicate the operating status of the serial I/O2 function and various errors. Three of the flags (b4 to b6) are only valid in the UART mode. The receive buffer full flag (b1) is cleared to "0" when the receive buffer is read.

The error detection is performed at the same time data is transferred from the receive shift register to the receive buffer register, and the receive buffer full flag is set. A writing to the serial I/O2 status register clears error flags OE, PE, FE, and SE (b3 to b6, respectively). Writing "0" to the serial I/O2 enable bit (SIOE : b7 of the serial I/O2 control register) also clears all the status flags, including the error flags.

All bits of the serial I/O2 status register are initialized to "0" at reset, but if the transmit enable bit (b4) of the serial I/O2 control register has been set to "1", the transmit shift register shift completion flag (b2) and the transmit buffer empty flag (b0) become "1".

### **[Serial I/O2 Transmit Buffer Register/Receive Buffer Register] TB/RB (001F16)**

The transmit buffer and the receive buffer are located in the same address. The transmit buffer is write-only and the receive buffer is read-only. If a character bit length is 7 bits, the MSB of data stored in the receive buffer is "0".

### **[Baud Rate Generator] BRG (003716)**

The baud rate generator determines the baud rate for serial transfer. With the 8-bit counter having a reload register, the baud rate generator divides the frequency of the count source by  $1/(n+1)$ , where n is the value written to the baud rate generator.

Fig. 40 Structure of serial I/O2 related register

### Notes

When setting the transmit enable bit to "1", the serial I/O2 transmit interrupt request bit is automatically set to "1". When not requiring the interrupt occurrence synchronized with the transmission enabled, take the following sequence.

- ① Set the serial I/O1 transmit interrupt enable bit to "0" (disabled).
- ② Set the transmit enable bit to "1".
- ③ Set the serial I/O1 transmit interrupt request bit to "0" after 1 or more instructions have been executed.
- ④ Set the serial I/O1 transmit interrupt enable bit to "1" (enabled).

# HARDWARE

## FUNCTIONAL DESCRIPTION

### Serial I/O3

The serial I/O3 function can be used only for 8-bit clock synchronous serial I/O.

All serial I/O pins are shared with port P9, which can be set with the serial I/O3 control register (address 0EEC16).

### [Serial I/O3 Control Register (SIO3CON)] 0EEC16

The serial I/O3 control register contains eight bits which control various serial I/O functions.

#### ● Serial I/O3 Operation

Either the internal clock or external clock can be selected as synchronous clock for serial I/O3 transfer.

The internal clock can use a built-in dedicated divider where 6 different clocks are selected. In the case of the internal clock used, transfer is started by a write signal to the serial I/O3 register (address 0EED16). When 8-bit data has been transferred, the SOUT3 pin goes to high impedance state.

In the case of the external clock used, the clock must be externally controlled. It is because the contents of serial I/O3 register is kept shifted while the clock is being input. Additionally, the function to put the SOUT3 pin high impedance state at completion of data transfer is not available.

The serial I/O3 interrupt request bit is set at completion of 8-bit data transfer, regardless of use of the internal clock or external clock.

## FUNCTIONAL DESCRIPTION

### FLD Automatic Display Pins

P0 to P6 are the pins capable of automatic display output for the FLD. The FLD starts operating by setting the automatic display control bit (bit 0 at address 0EF416) to "1". There is the FLD output function that outputs the RAM contents from the port every timing or the digit output function that drives the port high with a digit tim-

ing. The FLD can be displayed using the FLD output for the segments and the digit or FLD output for the digits. When using the FLD output for the digits, be sure to write digit display patterns to the RAM in advance. The remaining segment and digit lines can be used as general-purpose ports. Settings of each port are shown below.

**Table 10 Pins in FLD automatic display mode**

Port	Automatic display pin	Setting method
P0, P2	FLD0 to FLD15	The individual bits of the digit output set switch registers (addresses 0EF216, 0EF316) can set each pin to either an FLD port ("0") or a digit port ("1"). When the pins are set for the digit port, the digit pulse output function is enabled, so that the digit pulses can always be output regardless the value of FLD automatic display RAM.
P1, P3	FLD16 to FLD31	Setting the automatic display control bit (bit 0 of address 0EF416) to "1" can set these ports to the FLD exclusive use port.
P4, P5, P60 to P63	FLD32 to FLD51	The individual bits of the FLD/Port switch register (addresses 0EF916 to 0EFB16) can set each pin to either an FLD port ("1") or a general-purpose port ("0").
P64 to P67	FLD52 to FLD55	The individual bits of the port P6 FLD/Port switch register (address 0EFB16) can set each pin to either FLD port ("1") or general-purpose port ("0"). A variety of output pulses can be available by setting of the FLD output control register (address 0EFC16). The port output structure is the CMOS output. When using the port as a display pin, a driver IC must be installed externally.

**Fig. 49 Segment/Digit setting example**

### FLD Automatic Display RAM

The FLD automatic display RAM uses the 224 bytes of addresses 0E00<sub>16</sub> to 0EDF<sub>16</sub>. For FLD, the 3 modes of 16-timing•ordinary mode, 16-timing•gradation display mode and 32-timing mode are available depending on the number of timings and the use/not use of gradation display.

The automatic display RAM in each mode is as follows:

#### (1) 16-timing•ordinary mode

This mode is used when the display timing is 16 or less. The 112 bytes of addresses 0E70<sub>16</sub> to 0EDF<sub>16</sub> are used as a FLD display data store area. Because addresses 0E00<sub>16</sub> to 0E6F<sub>16</sub> are not used as the automatic display RAM, they can be the ordinary RAM.

#### (2) 16-timing•gradation display mode

This mode is used when the display timing is 16 or less, in which mode each segment can be set for dark or bright display. The 224 bytes of addresses 0E00<sub>16</sub> to 0EDF<sub>16</sub> are used. The 112 bytes of addresses 0E70<sub>16</sub> to 0EDF<sub>16</sub> are used as an FLD display data store area, while the 112 bytes of addresses 0E00<sub>16</sub> to 0E6F<sub>16</sub> are used as a gradation display control data store area.

#### (3) 32-timing mode

This mode is used when the display timing is 16 or greater. This mode can be used for up to 32-timing.

The 224 bytes of addresses 0E00<sub>16</sub> to 0EDF<sub>16</sub> are used as an FLD display data store area.

The FLD data pointer (address 0EF8<sub>16</sub>) is a register to count display timings. This pointer has a reload register. When the pointer underflow occurs, it starts counting over again after being reloaded with the initial value in the reload register. Make sure that (the timing counts – 1) is set to the FLD data pointer. When writing data to this address, the data is written to the FLD data pointer reload register; when reading data from this address, the value in the FLD data pointer is read.

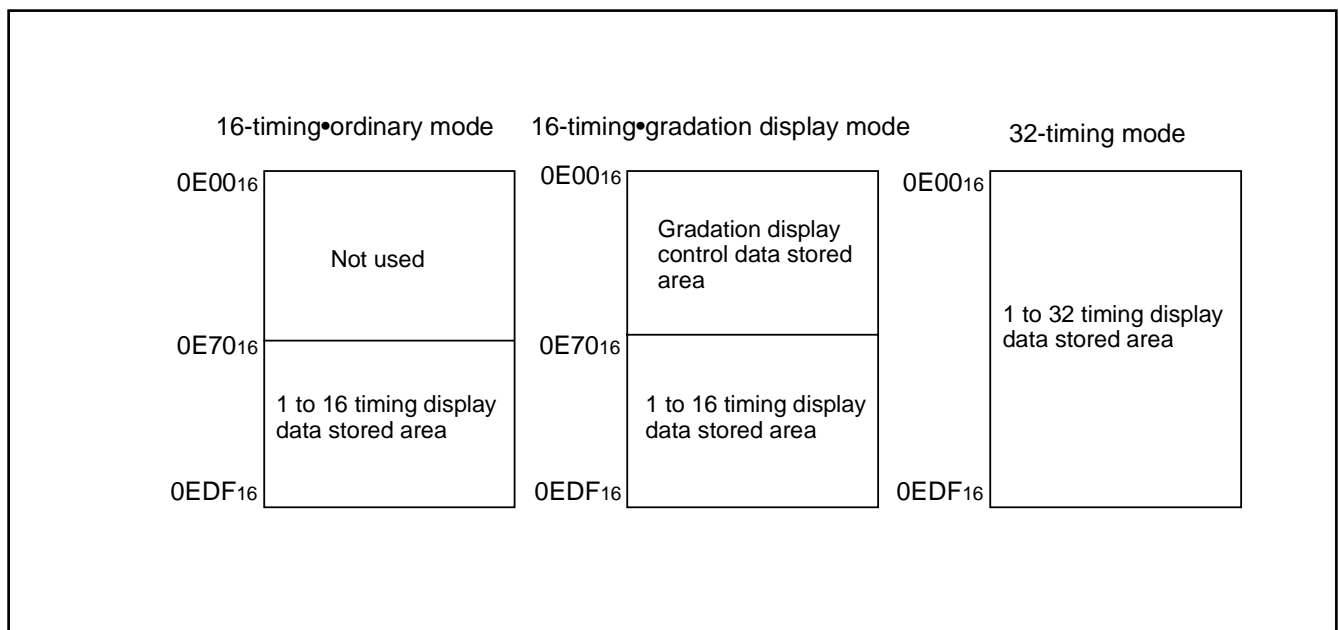

Fig. 50 FLD automatic display RAM assignment

# HARDWARE

## FUNCTIONAL DESCRIPTION

### Data Setup

#### (1) 16-timing•ordinary mode

The area of addresses 0E70<sub>16</sub> to 0EDF<sub>16</sub> are used as a FLD automatic display RAM.

When data is stored in the FLD automatic display RAM, the last data of FLD port P6 is stored at address 0E70<sub>16</sub>, the last data of FLD port P5 is stored at address 0E80<sub>16</sub>, the last data of FLD port P4 is stored at address 0E90<sub>16</sub>, the last data of FLD port P3 is stored at address 0EA0<sub>16</sub>, the last data of FLD port P1 is stored at address 0EB0<sub>16</sub>, the last data of FLD port P0 is stored at address 0EC0<sub>16</sub>, and the last data of FLD port P2 is stored at address 0ED0<sub>16</sub>, to assign in sequence from the last data respectively.

The first data of the FLD port P6, P5, P4, P3, P1, P0, and P2 is stored at an address which adds the value of (the timing number – 1) to the corresponding addresses 0E70<sub>16</sub>, 0E80<sub>16</sub>, 0E90<sub>16</sub>, 0EA0<sub>16</sub>, 0EB0<sub>16</sub>, 0EC0<sub>16</sub> and 0ED0<sub>16</sub>.

Set the FLD data pointer reload register to the value given by (the timing number – 1).

#### (2) 16-timing•gradation display mode

Display data setting is performed in the same way as that of the 16-timing•ordinary mode. Gradation display control data is arranged at an address resulting from subtracting 0070<sub>16</sub> from the display data store address of each timing and pin. Bright display is performed by setting “0”, and dark display is performed by setting “1”.

#### (3) 32-timing Mode

The area of addresses 0E00<sub>16</sub> to 0EDF<sub>16</sub> is used as a FLD automatic display RAM.

When data is stored in the FLD automatic display RAM, the last data of FLD port P6 is stored at address 0E00<sub>16</sub>, the last data of FLD port P5 is stored at address 0E20<sub>16</sub>, the last data of FLD port P4 is stored at address 0E40<sub>16</sub>, the last data of FLD port P3 is stored at address 0E60<sub>16</sub>, the last data of FLD port P1 is stored at address 0E80<sub>16</sub>, the last data of FLD port P0 is stored at address 0EA0<sub>16</sub>, and the last data of FLD port P2 is stored at address 0EC0<sub>16</sub>, to assign in sequence from the last data respectively.

The first data of the FLD port P6, P5, P4, P3, P1, P0, and P2 is stored at an address which adds the value of (the timing number – 1) to the corresponding addresses 0E00<sub>16</sub>, 0E20<sub>16</sub>, 0E40<sub>16</sub>, 0E60<sub>16</sub>, 0E80<sub>16</sub>, 0EA0<sub>16</sub> and 0EC0<sub>16</sub>.

Set the FLD data pointer reload register to the value given by (the timing number – 1).

Fig. 51 Example of using FLD automatic display RAM in 16-timing•ordinary mode

Fig. 52 Example of using FLD automatic display RAM in 16-timing\*gradation display mode

## FUNCTIONAL DESCRIPTION

Fig. 53 Example of using FLD automatic display RAM in 32-timing mode

### Timing Setting

Each timing is set by the FLDC mode register, Tdisp time set register, Toff1 time set register, and Toff2 time set register.

#### (1) Tdisp time setting

The Tdisp time means the length of display timing. In non-gradation display mode, it consists of the FLD display output term and the Toff1 time. In gradation display mode, it consists of the display output term and the Toff1 time plus a low signal output term for dark display. Set the Tdisp time by the Tdisp counter count source selection bit of the FLDC mode register and the Tdisp time set register. Supposing that the value of the Tdisp time set register is  $n$ , the Tdisp time is represented as  $T_{disp} = (n+1) \times t$  ( $t$ : count source). When the Tdisp counter count source selection bit of the FLDC mode register is "0" and the value of the Tdisp time set register is 200 (C8<sub>16</sub>), the Tdisp time is:  $T_{disp} = (200 + 1) \times 4.0 \mu\text{s}$  (at  $X_{IN} = 4 \text{ MHz}$ ) = 804  $\mu\text{s}$ . When reading the Tdisp time set register, the counting value is read out.

#### (2) Toff1 time setting

The Toff1 time means a non-output (low signal output) time to prevent blurring of FLD and for dimmer display. Use the Toff1 time set register to set this Toff1 time. Make sure the value set to Toff1 is smaller than Tdisp and Toff2. Supposing that the value of the Toff1 time set register is  $n_1$ , the Toff1 time is represented as  $T_{off1} = n_1 \times t$ . When the Tdisp counter count source selection bit of the FLDC mode register is "0" and the value of the Toff1 time set register is 30 (1E<sub>16</sub>),  $T_{off1} = 30 \times 4.0 \mu\text{s}$  (at  $X_{IN} = 4 \text{ MHz}$ ) = 120  $\mu\text{s}$ . Be sure to set the value of 03<sub>16</sub> or more to the Toff1 time set register (address 0EF6<sub>16</sub>).

#### (3) Toff2 time setting

The Toff2 time is time for dark display. For bright display, the FLD display output remains effective until the counter that is counting Tdisp underflows. For dark display, however, "L" (or "off") signal is output when the counter that is counting Toff2 underflows. This Toff2 time setting is valid only for FLD ports which are in the gradation display mode and whose gradation display control RAM value is "1".

Set the Toff2 time by the Toff2 time set register. Make sure the value set to Toff2 is smaller than Tdisp but larger than Toff1. Supposing that the value of the Toff2 time set register is  $n_2$ , the Toff2 time is represented as  $T_{off2} = n_2 \times t$ . When the Tdisp counter count source selection bit of the FLDC mode register is "0" and the value of the Toff2 time set register is 180 (B4<sub>16</sub>),  $T_{off2} = 180 \times 4.0 \mu\text{s}$  (at  $X_{IN} = 4 \text{ MHz}$ ) = 720  $\mu\text{s}$ .

When bit 7 of the FLD output control register (address 0EFC<sub>16</sub>) is set to "1", be sure to set the value of 03<sub>16</sub> or more to the Toff2 time set register (address 0EF7<sub>16</sub>).

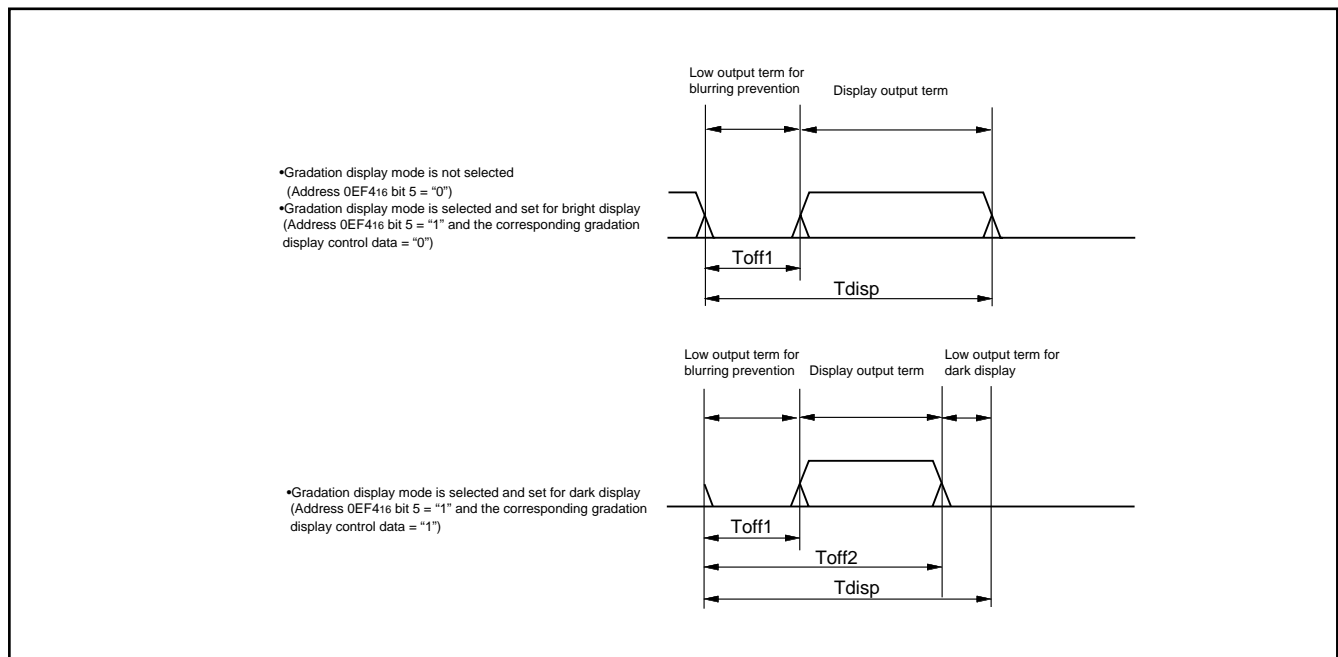

Fig. 54 FLD and digit output timing

# HARDWARE

## FUNCTIONAL DESCRIPTION

### FLD Automatic Display Start

Automatic display starts by setting both the automatic display control bit (bit 0 of address 0EF416) and the display start bit (bit 1 of address 0EF416) to "1". The RAM contents at a location apart from the start address of the automatic display RAM for each port by (FLD data pointer (address 0EF816) - 1) are output to each port. The FLD data pointer (address 0EF816) counts down in the Tdisp interval. When the count results in "FF16", the pointer is reloaded and starts counting over again. Before setting the display start bit (bit 1 of address 0EF416) to "1", be sure to set the FLD/port switch registers, digit output set switch registers, FLDC mode register, Tdisp time set register, Toff1 time set register, Toff2 time set register, and FLD data pointer.

During FLD automatic display, the display start bit always keeps "1", and FLD automatic display can be interrupted by writing "0" to this bit.

### Key-scan and Interrupt

Either the FLD digit interrupt or FLD blanking interrupt can be selected using the Tscan control bits (bits 2, 3 of address 0EF416).

The FLD digit interrupt is generated when the Toff1 time in each timing expires (at rising edge of digit output). Key scanning that makes use of FLD digits can be achieved using each FLD digit interrupt. To use FLD digit interrupts for key scanning, follow the procedure described below:

- (1) Read the port value each time the interrupt occurs.
- (2) The key is fixed on the last digit interrupt.

The output digit positions can be determined by reading the FLD data pointer (address 0EF816).

Fig. 55 Timing using digit interrupt

The FLD blanking interrupt is generated when the FLD data pointer (address 0EF816) reaches "FF16". The FLD automatic display output is turned off for a duration of  $1 \times T_{disp}$ ,  $2 \times T_{disp}$ , or  $3 \times T_{disp}$  depending on post-interrupt settings. During this time, key scanning that makes use of FLD segments can be achieved. When the key scanning is performed with the segment during key-scan blanking time  $T_{scan}$ , follow the procedure described below:

- (1) Write "0" to the automatic display control bit (bit 0 of address 0EF416).
- (2) Set the port corresponding to the segment for key scanning to the output port.
- (3) Perform key scanning.
- (4) Write "1" to the automatic display control bit.

### ■ Note

When performing a key-scan according to the above steps 1 to 4, take the following points into consideration.

1. Do not set the display start bit (bit 1 of address 0EF416) to "0".
2. Do not set "1" in the ports corresponding to digits.

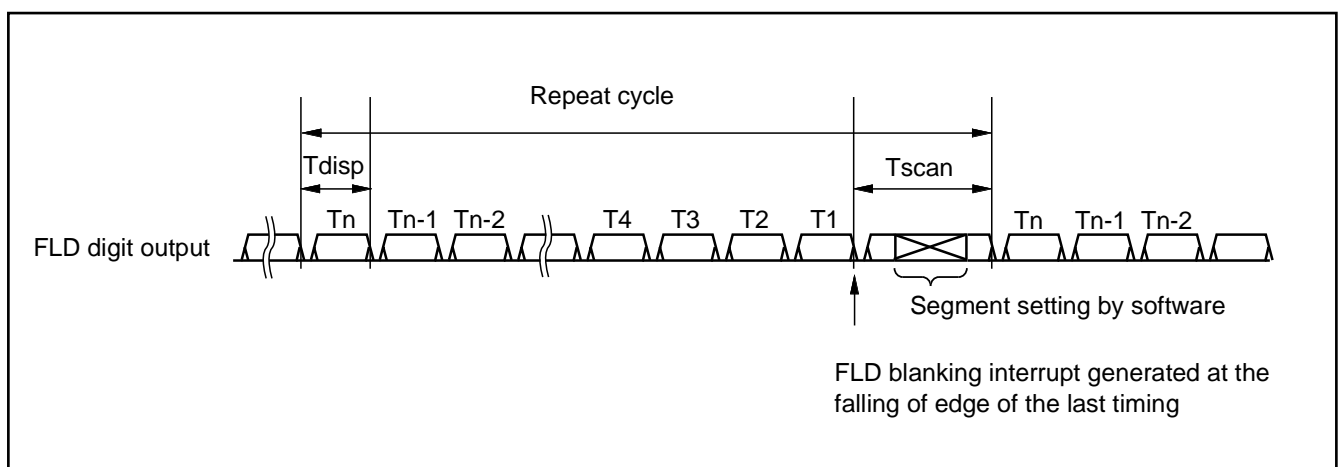

Fig. 56 Timing using FLD blanking interrupt

# HARDWARE

## FUNCTIONAL DESCRIPTION

### P64 to P67 Expansion Function

Ports P64 to P67 are CMOS output structure. FLD digit outputs can be increased as many as 16 lines by connecting a decoder converting 4-bit to 16-bit data to these ports. P64 to P67 have the function to allow for connection to a decoder converting 4-bit to 16-bit data.

### (1) P64 to P67 Toff invalid function

This function disables the Toff1 time and Toff2 time and outputs display data for the duration of Tdisp. (See Figure 57.) This can be achieved by setting the P64 to P67 Toff invalid bit (bit 2 of address 0EFC16) to "1".

### (2) Dimmer signal output function

This function allows a dimmer signal creation signal to be output from DIMOUT (P73). The dimmer function can be achieved by controlling the decoder with this signal. (See Figure 57.) This function can be set by setting P73 dimmer output control bit (bit 4 of address 0EFC16) to "1".

Unlike the Toff section generating/nothing function, this function disables all display data.

### (3) P64 to P67 FLD output reverse function

P64 to P67 have the function to reverse the polarity of the FLD output. This function is useful in adjusting the polarity when using an externally installed driver.

The output polarity can be reversed by setting the P64 to P67 output reverse bit of the FLD output control register (bit 0 of address 0EFC16) to "1".

### ■ Note

In the case of gradation display mode and dark display, P64 to P67 Toff invalid function is disabled.

Fig. 57 P64 to P67 FLD output pulses

### Toff Section Generate/Nothing Function

The function is for reduction of useless noises which generated as every switching of ports, because of the combined capacity of among FLD ports. When the continuous data is output to each FLD port, the Toff1 section of the continuous parts is not generated. (See Figure 58)

If it needs Toff1 section on FLD pulses, set the generating /not of CMOS port Toff section selection bit (bit 5 of address 0EFC16) to "1" and set the generating /not of high-breakdown-voltage port Toff section selection bit to "1".

High-breakdown-voltage ports (P2, P0, P1, P3, P4, P5, P63 to P60, total 52 pins) generate Toff1 section by setting the generating /not of high-breakdown-voltage port Toff section selection bit to "1".

The CMOS ports (P64 to P67, total 4 pins ) generate Toff1 section by setting the generating /not of CMOS port Toff section selection bit to "1".

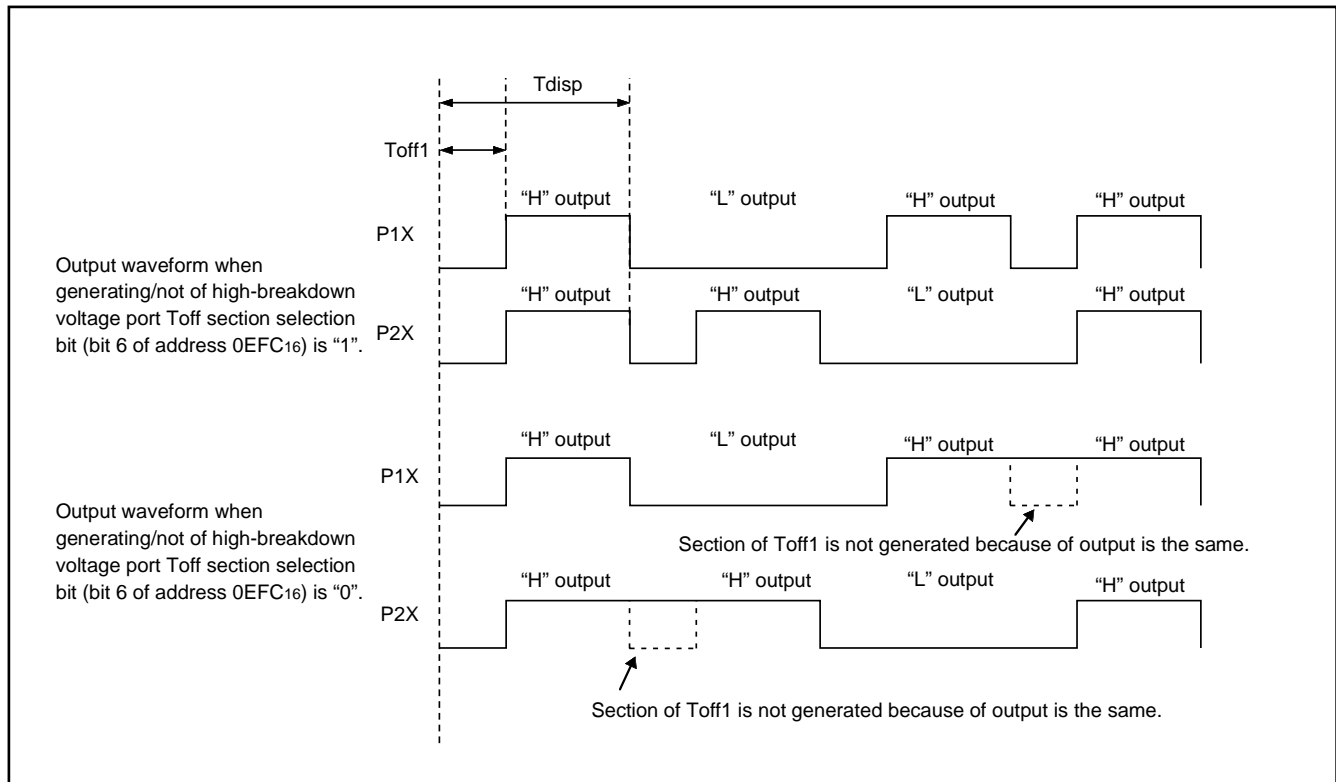

Fig. 58 Toff section generating/nothing function

### Toff2 SET/RESET Switch Function

In gradation display mode, the values set by the Toff2 time set register (TOFF2) are effective. When the Toff2 SET/RESET switch bit of FLD output control register (bit 7 of address 0EFC16) is "0", RAM data is output to the FLD output ports (SET) at the time that is set by TOFF1 and it is turned to "0" (RESET) at the time that is set by TOFF2.

When Toff2 SET/RESET switch bit is "1", RAM data is output (SET) at the time that is set by TOFF2 and it is turned to "0" (RESET) when the Tdisp time expires.

#### ■ Note

In the case of gradation display mode and dark display, the Toff section generate/nothing function is disabled.

# HARDWARE

## FUNCTIONAL DESCRIPTION

### Digit Pulses Output Function

P00 to P07 and P20 to P27 can output digit pulses by using the digit output set switch registers. Set the digit output set switch registers by setting as many consecutive 1s as the timing count from P20. The contents of FLD automatic display RAM for the ports that have been selected for digit output are disabled, and the pulse shown in Figure 59 is output automatically.

The output timing consists of Tdisp time and Toff1 time, and Toff2 time does not exist.

Because the contents of FLD automatic display RAM are disabled, the segment data can be changed easily even when segment data and digit data coexist at the same address in the FLD automatic display RAM.

This function is effective in 16-timing ordinary mode and 16-timing gradation display mode. If a value is set exceeding the timing count (FLD data pointer reload register's set value + 1) for any port, the output of such port is "L".

Fig. 59 Digit pulses output function

### A-D CONVERTER

The 38B7 group has a 10-bit A-D converter. The A-D converter performs successive approximation conversion.

#### [A-D Conversion Register] ADH, ADL

One of these registers is a high-order register, and the other is a low-order register. The high-order 8 bits of a conversion result is stored in the A-D conversion register (high-order) (address 003416), and the low-order 2 bits of the same result are stored in bit 7 and bit 6 of the A-D conversion register (low-order) (address 003316).

During A-D conversion, do not read these registers.

#### [AD/DA Control Register] ADCON

This register controls A-D converter. Bits 3 to 0 are analog input pin selection bits. Bit 4 is an AD conversion completion bit and "0" during A-D conversion. This bit is set to "1" upon completion of A-D conversion.

A-D conversion is started by writing "0" in this bit.

#### [Comparison Voltage Generator]

The comparison voltage generator divides the voltage between AVss and VREF by 1024, and outputs the divided voltages.

#### [Channel Selector]

The channel selector selects one of the input ports PA7/AN7-PA0/AN0, and P97/BUZ02/AN15 to P90/SIN3/AN8 and inputs it to the comparator.

#### [Comparator and Control Circuit]

The comparator and control circuit compares an analog input voltage with the comparison voltage and stores the result in the A-D conversion register. When an A-D conversion is completed, the control circuit sets the AD conversion completion bit and the AD conversion interrupt request bit to "1".

Note that the comparator is constructed linked to a capacitor, so that set  $f(XIN)$  to at least 250 kHz during A-D conversion. Additionally, bit 7 of the CPU mode register (address 003B16) must be set to "0".

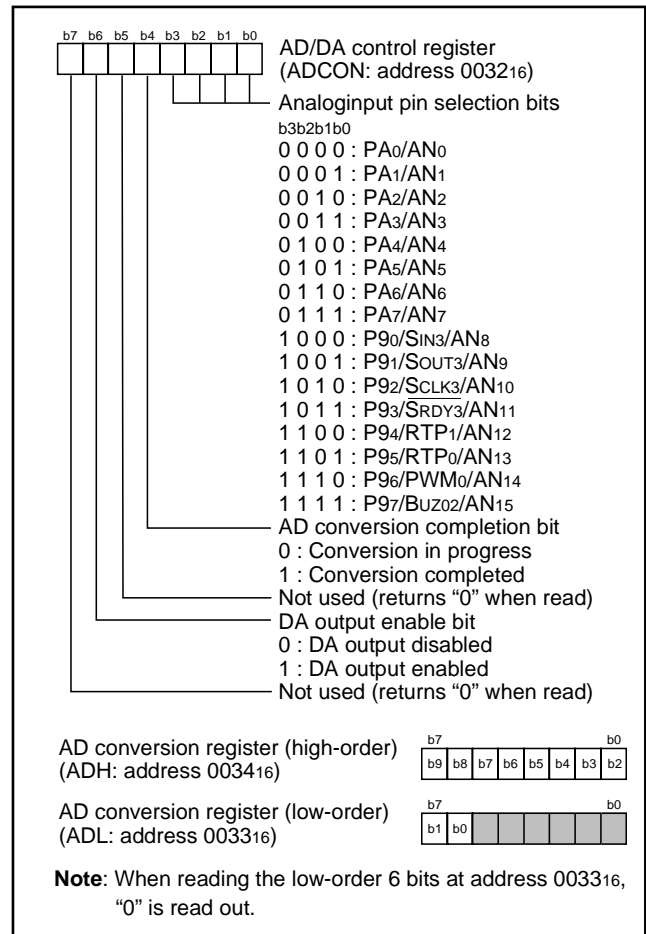

Fig. 60 Structure of AD/DA control register

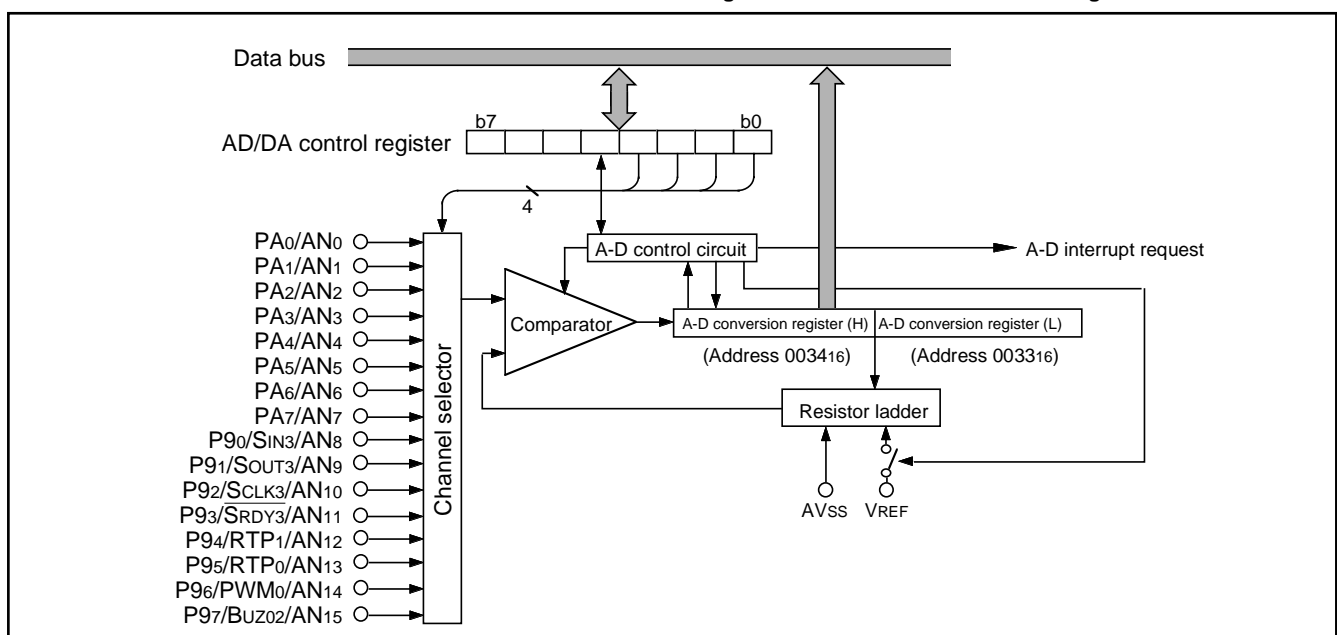

Fig. 61 Block diagram of A-D converter

# HARDWARE

## FUNCTIONAL DESCRIPTION

### D-A CONVERTER

The 38B7 group has one internal D-A converter with 8-bit resolution.

The D-A conversion is performed by setting the value in the D-A conversion register. The result of D-A conversion is output from the DA pin by setting the DA output enable bit to "1".

When using the D-A converter, the PB0/DA port direction register bit must be set to "0" (input status).

The output analog voltage  $V$  is determined by the value  $n$  (decimal notation) in the D-A conversion register as follows:

$$V = V_{REF} \times n / 256 \quad (n = 0 \text{ to } 255)$$

Where  $V_{REF}$  is the reference voltage.

At reset, the D-A conversion register is cleared to "0016", and the DA output enable bit is cleared to "0", and PB0/DA pin becomes high impedance.

The DA output does not have buffers. Accordingly, connect an external buffer when driving a low-impedance load.

Set  $V_{CC}$  to 3.0 V or more when using the D-A converter.

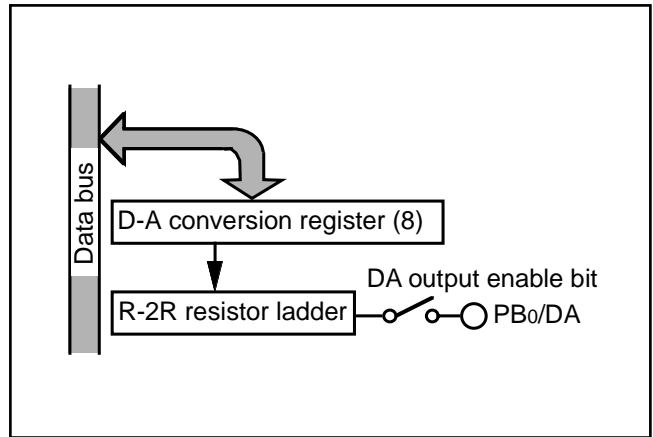

Fig. 62 Block diagram of D-A converter

Fig. 63 Equivalent connection circuit of D-A converter

### PWM (Pulse Width Modulation)

The 38B7 group has a PWM function with a 14-bit resolution. When the oscillation frequency  $X_{IN}$  is 4 MHz, the minimum resolution bit width is 250 ns and the cycle period is 4096  $\mu$ s. The PWM timing generator supplies a PWM control signal based on a signal that is the frequency of the  $X_{IN}$  clock.

The explanation in the rest assumes  $X_{IN} = 4$  MHz.

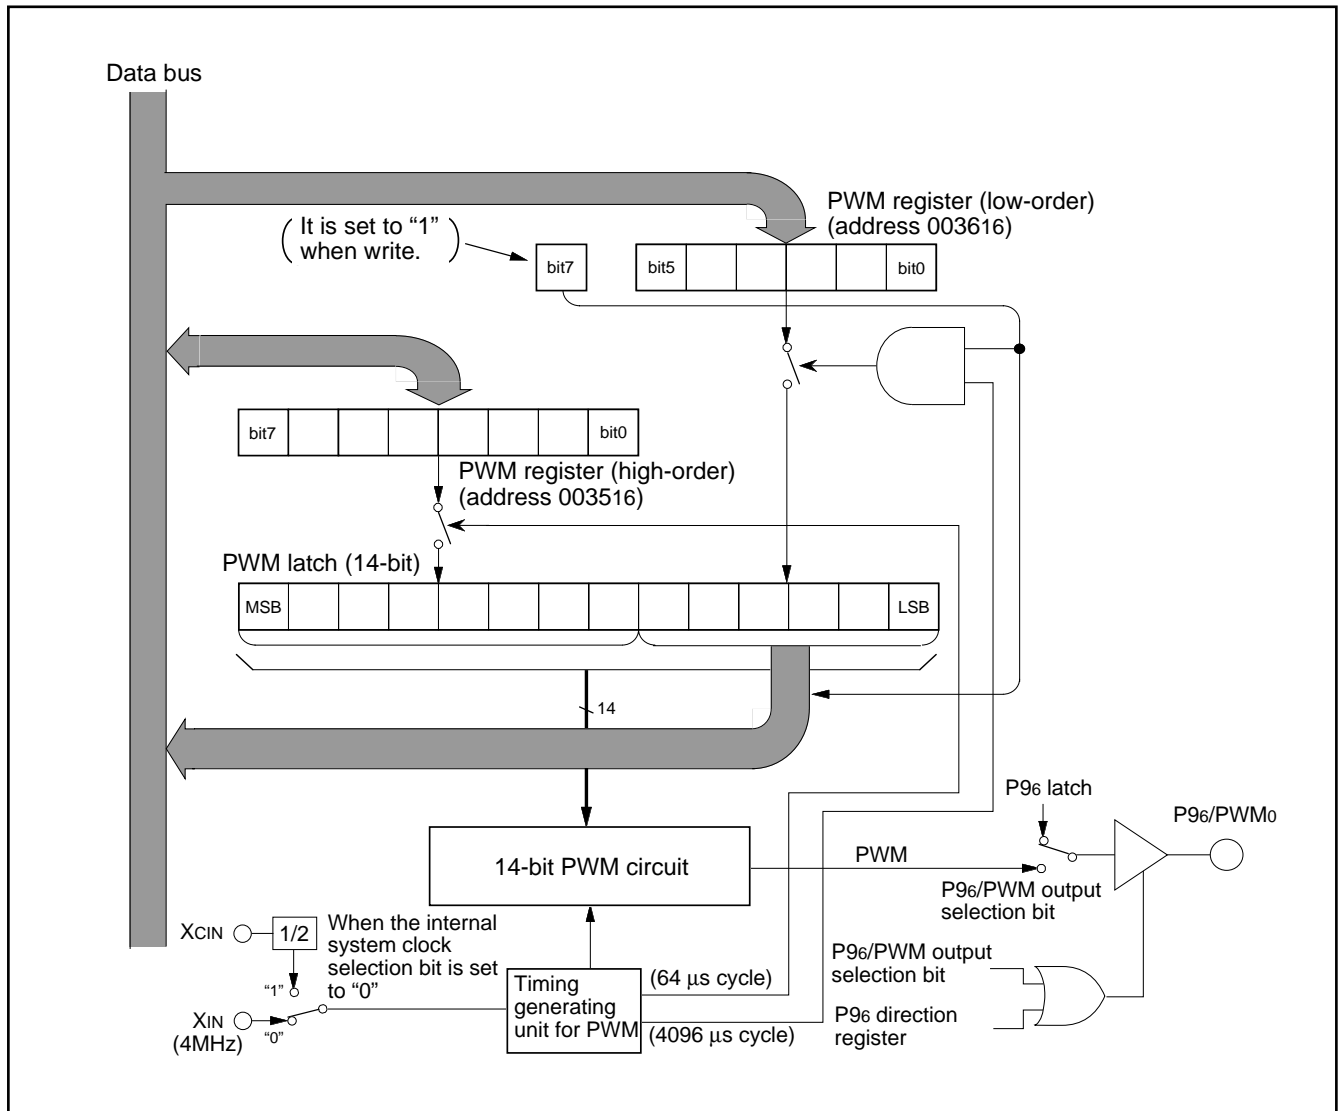

Fig. 64 PWM block diagram

# HARDWARE

## FUNCTIONAL DESCRIPTION

### Data Setup

The PWM output pin also function as port P96. Set port P96 to be the PWM output pin by setting bit 0 of the PWM control register (address 002616) to "1". The high-order 8 bits of output data are set in the high-order PWM register PWMH (address 003516) and the low-order 6 bits are set in the low-order PWM register PWML (address 003616).

### PWM Operation

The timing of the 14-bit PWM function is shown in Figure 65. The 14-bit PWM data is divided into the low-order 6 bits and the high-order 8 bits in the PWM latch.

The high-order 8 bits of data determine how long an "H" level signal is output during each sub-period. There are 64 sub-periods in each period, and each sub-period  $t$  is  $256 \times \tau$  ( $= 64 \mu\text{s}$ ) long. The signal's "H" has a length equal to  $N$  times  $\tau$ , and its minimum resolution = 250 ns.

The last bit of the sub-period becomes the ADD bit which is specified either "H" or "L," by the contents of PWML. As shown in Table 11, the ADD bit is decided either "H" or "L."

That is, only in the sub-period  $t_m$  shown in Table 11 in the PWM cycle period  $T = 64 t$ , the "H" duration is lengthened during the minimum resolution width  $\tau$  period in comparison with the other period.

For example, if the high-order eight bits of the 14-bit data are "0316" and the low-order six bits are "0516," the length of the "H" level output in sub-periods  $t_8, t_{24}, t_{32}, t_{40}$  and  $t_{56}$  is  $4 \tau$ , and its length  $3 \tau$  in all other sub-periods.

Time at the "H" level of each sub-period almost becomes equal because the time becomes length set in the high-order 8 bits or becomes the value plus  $t$ , and this sub-period  $t$  ( $= 64 \mu\text{s}$ , approximate 15.6 kHz) becomes cycle period approximately.

### Transfer From Register to Latch

Data written to the PWML register is transferred to the PWM latch once in each PWM period (every 4096  $\mu\text{s}$ ), and data written to the PWMH register is transferred to the PWM latch once in each sub-period (every 64  $\mu\text{s}$ ). Pulses output from the PWM output pin correspond to this latch contents.

When the PWML register is read, the contents of the latch are read. However, bit 7 of the PWML register indicates whether the transfer to the PWM latch is completed: the transfer is completed when bit 7 is "0", it is not done when bit 7 is "1".

**Table 11 Relationship between low-order 6-bit data and setting period of ADD bit**

Low-order 6-bit data	Sub-periods $t_m$ lengthened ( $m = 0$ to 63)
0 0 0 0 0 0	None
0 0 0 0 0 1	$m = 32$
0 0 0 0 1 0	$m = 16, 48$
0 0 0 1 0 0	$m = 8, 24, 40, 56$
0 0 1 0 0 0	$m = 4, 12, 20, 28, 36, 44, 52, 60$
0 1 0 0 0 0	$m = 2, 6, 10, 14, 18, 22, 26, 30, 34, 38, 42, 46, 50, 54, 58, 62$

## FUNCTIONAL DESCRIPTION

### INTERRUPT INTERVAL DETERMINATION FUNCTION

The 38B7 group has an interrupt interval determination circuit. This interrupt interval determination circuit has an 8-bit binary up counter. Using this counter, it determines a duration of time from the rising edge (falling edge) of an input signal pulse on the P72/INT2 pin to the rising edge (falling edge) of the signal pulse that is input next.

How to determine the interrupt interval is described below.

1. Enable the INT2 interrupt by setting bit 2 of the interrupt control register 1 (address 003E16). Select the rising interval or falling interval by setting bit 2 of the interrupt edge selection register (address 003A16).
2. Set bit 0 of the interrupt interval determination control register (address 003116) to "1" (interrupt interval determination operating).
3. Select the sampling clock of 8-bit binary up counter by setting bit 1 of the interrupt interval determination control register.
4. When the signal of polarity which is set on the INT2 pin (rising or falling edge) is input, the 8-bit binary up counter starts counting up of the selected counter sampling clock.
5. When the signal of polarity selected above is input again, the value of the 8-bit binary up counter is transferred to the interrupt interval determination register (address 003016), and the remote control interrupt request occurs. Immediately after that, the 8-bit binary up counter continues to count up again from "0016".
6. When count value reaches "FF16", the 8-bit binary up counter stops counting up. Then, simultaneously when the next counter sampling clock is input, the counter sets value "FF16" to the interrupt interval determination register to generate the counter overflow interrupt request.

### Noise Filter

The P72/INT2 pin builds in the noise filter.

The noise filter operation is described below.

1. Select the sampling clock of the input signal with bits 2 and 3 of the interrupt interval determination control register. When not using the noise filter, set "0016".
2. The P72/INT2 input signal is sampled in synchronization with the selected clock. When sampling the same level signal in a series of three sampling, the signal is recognized as the interrupt signal, and the interrupt request occurs.

When setting bit 4 of interrupt interval determination control register to "1", the interrupt request can occur at both rising and falling edges.

When using the noise filter, set the minimum pulse width of the INT2 input signal to 3 cycles or more of the sample clock.

### BUZZER OUTPUT CIRCUIT

The 38B7 group has a buzzer output circuit. One of 1 kHz, 2 kHz and 4 kHz (at  $X_{IN} = 4.19$  MHz) frequencies can be selected by the buzzer output control register (address 0EFD16). Either P77/BUZ01 or P97/BUZ02/AN15 can be selected as a buzzer output port by the output port selection bits (b2 and b3 of address 0EFD16).

The buzzer output is controlled by the buzzer output ON/OFF bit (b4).

**Note:** In the low-speed mode, a buzzer output is made OFF.

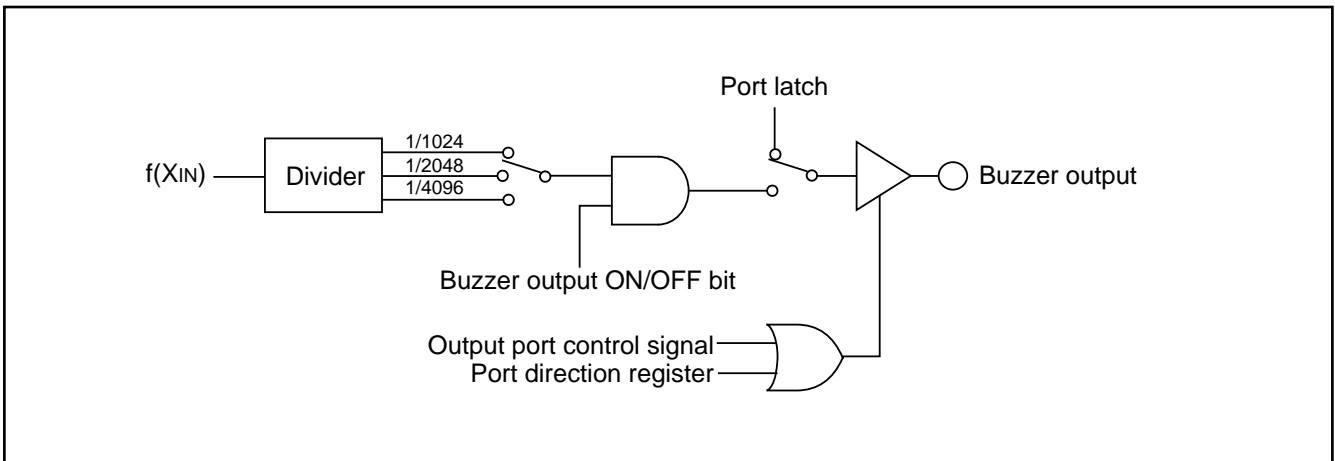

Fig. 74 Block diagram of buzzer output circuit

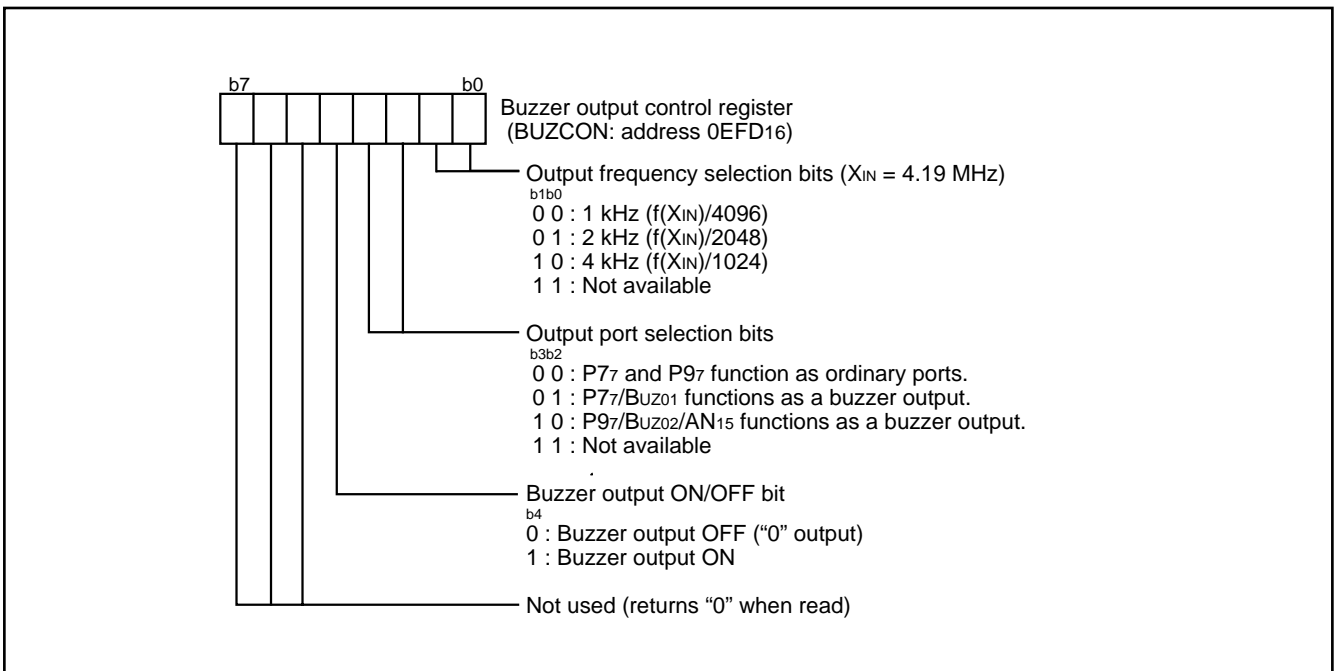

Fig. 75 Structure of buzzer output control register

## FUNCTIONAL DESCRIPTION

### RESET CIRCUIT

To reset the microcomputer,  $\overline{\text{RESET}}$  pin should be held at an "L" level for 2  $\mu\text{s}$  or more. Then the  $\overline{\text{RESET}}$  pin is returned to an "H" level (the power source voltage should be between 2.7 V and 5.5 V, and the oscillation should be stable), reset is released. After the reset is completed, the program starts from the address contained in address FFFD<sub>16</sub> (high-order byte) and address FFFC<sub>16</sub> (low-order byte). Make sure that the reset input voltage is less than 0.54 V for Vcc of 2.7 V (switching to the high-speed mode, a power source voltage must be between 4.0 V and 5.5 V).

# HARDWARE

## FUNCTIONAL DESCRIPTION

### CLOCK GENERATING CIRCUIT

The 38B7 group has two built-in oscillation circuits. An oscillation circuit can be formed by connecting a resonator between XIN and XOUT or XCIN and XCOUT. Use the circuit constants in accordance with the resonator manufacturer's recommended values. No external resistor is needed between XIN and XOUT since a feedback resistor exists on-chip. However, an external feedback resistor is needed between XCIN and XCOUT.

Immediately after power on, only the XIN oscillation circuit starts oscillating, and XCIN and XCOUT pins function as I/O ports.

### Frequency Control

#### (1) Middle-speed mode

The internal system clock is the frequency of XIN divided by 4. After reset, this mode is selected.

#### (2) High-speed mode

The internal system clock is the frequency of XIN.

#### (3) Low-speed mode

The internal system clock is the frequency of XCIN divided by 2.

#### ■ Note

If you switch the mode between middle/high-speed and low-speed, stabilize both XIN and XCIN oscillations. The sufficient time is required for the sub clock to stabilize, especially immediately after power on and at returning from stop mode. When switching the mode between middle/high-speed and low-speed, set the frequency on condition that  $f(XIN) > 3 \cdot f(XCIN)$ .

#### (4) Low power consumption mode

The low power consumption operation can be realized by stopping the main clock XIN in low-speed mode. To stop the main clock, set the main clock stop bit (bit 5) of the CPU mode register to "1". When the main clock XIN is restarted (by setting the main clock stop bit to "0"), set enough time for oscillation to stabilize.

### Oscillation Control

#### (1) Stop mode

If the STP instruction is executed, the internal system clock stops at an "H" level, and XIN and XCIN oscillators stop. Timer 1 is set to "FF16" and timer 2 is set to "0116".

Either XIN divided by 8 or XCIN divided by 16 is input to timer 1 as count source, and the output of timer 1 is connected to timer 2. The bits of the timer 12 mode register are cleared to "0". Set the interrupt enable bits of the timer 1 and timer 2 to disabled ("0") before executing the STP instruction. Oscillator restarts when an external interrupt is received, but the internal system clock is not supplied to the CPU until timer 2 underflows. This allows time for the clock circuit oscillation to stabilize.

#### (2) Wait mode

If the WIT instruction is executed, the internal system clock stops at an "H" level. The states of XIN and XCIN are the same as the state before executing the WIT instruction. The internal system clock restarts at reset or when an interrupt is received. Since the oscillator does not stop, normal operation can be started immediately after the clock is restarted.

### Power Dissipation Calculating Method

(Fixed number depending on microcomputer's standard)

- $V_{OH}$  output fall voltage of high-breakdown port  
2 V (max.); | Current value | = at 18 mA
- Resistor value = 48 k $\Omega$  (min.)
- Power dissipation of internal circuit (CPU, ROM, RAM etc.)  
= 5 V  $\times$  15 mA = 75 mW

(Fixed number depending on use condition)

- Apply voltage to VEE pin:  $V_{cc} - 45$  V
- Timing number a; digit number b; segment number c
- Ratio of Toff time corresponding Tdisp time: 1/16
- Turn ON segment number during repeat cycle: d
- All segment number during repeat cycle: e (= a  $\times$  c)
- Total number of built-in resistor: for digit, f; for segment, g
- Digit pin current value h (mA)
- Segment pin current value i (mA)

- (1) Digit pin power dissipation  
{h  $\times$  b  $\times$  (1 - Toff / Tdisp)  $\times$  voltage} / a
- (2) Segment pin power dissipation  
{i  $\times$  d  $\times$  (1 - Toff / Tdisp)  $\times$  voltage} / a
- (3) Pull-down resistor power dissipation (digit)  
{power dissipation per 1 digit  $\times$  (b  $\times$  f / b)  $\times$  (1 - Toff / Tdisp)} / a
- (4) Pull-down resistor power dissipation (segment)  
{power dissipation per 1 segment  $\times$  (d  $\times$  g / c)  $\times$  (1 - Toff / Tdisp)} / a
- (5) Internal circuit power dissipation (CPU, ROM, RAM etc.)  
= 190 mW

## FUNCTIONAL DESCRIPTION

### FLASH MEMORY MODE

The M38B79FF has the flash memory mode in addition to the normal operation mode (microcomputer mode). The user can use this mode to perform read, program, and erase operations for the internal flash memory.

The M38B79FF has three modes the user can choose: the parallel input/output and serial input/output mode, where the flash memory is handled by using the external programmer, and the CPU reprogramming mode, where the flash memory is handled by the central processing unit (CPU). The following explains these modes.

#### (1) Flash memory mode 1 (parallel I/O mode)

The parallel I/O mode can be selected by connecting wires as shown in Figures 85 and supplying power to the VCC and VPP pins. In this mode, the M38B79FF operates as an equivalent of MITSUBISHI's CMOS flash memory M5M28F101. However, because the M38B79FF's internal memory has a capacity of 60 Kbytes, programming is available for addresses 01000<sub>16</sub> to 0FFFF<sub>16</sub>, and make sure that the data in addresses 00000<sub>16</sub> to 00FFF<sub>16</sub> and addresses 10000<sub>16</sub> to 1FFFF<sub>16</sub> are FF<sub>16</sub>. Note also that the M38B79FF does not contain a facility to read out a device identification code by applying a high voltage to address input (A<sub>9</sub>). Be careful not to erratically set program conditions when using a general-purpose PROM programmer.

Table 12 shows the pin assignments when operating in the parallel input/output mode.

**Table 12 Pin assignments of M38B79FF when operating in the parallel input/output mode**

	M38B79FF	M5M28F101
Vcc	Vcc	Vcc
VPP	CNVss	VPP
Vss	Vss	Vss
Address input	Ports P0, P1, P31	A0–A16
Data I/O	Port P2	D0–D7
$\overline{\text{CE}}$	P36	$\overline{\text{CE}}$
$\overline{\text{OE}}$	P37	$\overline{\text{OE}}$
$\overline{\text{WE}}$	P33	$\overline{\text{WE}}$

**Table 13 Assignment states of control input and each state**

Mode	State	Pin	$\overline{\text{CE}}$	$\overline{\text{OE}}$	$\overline{\text{WE}}$	VPP	Data I/O
Read-only	Read		VIL	VIL	VIH	VPLL	Output
	Output disable		VIL	VIH	VIH	VPLL	Floating
	Standby		VIH	×	×	VPLL	Floating
Read/Write	Read		VIL	VIL	VIH	VPPH	Output
	Output disable		VIL	VIH	VIH	VPPH	Floating
	Standby		VIH	×	×	VPPH	Floating
	Write		VIL	VIH	VIL	VPPH	Input

Note: × can be VIL or VIH.

### Functional Outline (parallel input/output mode)

In the parallel input/output mode, the M38B79FF allow the user to choose an operation mode between the read-only mode and the read/write mode (software command control mode) depending on the voltage applied to the VPP pin. When VPP = VPLL, the read-only mode is selected, and the user can choose one of three states (e.g., read, output disable, or standby) depending on inputs to the CE, OE, and WE pins. When VPP = VPPH, the read/write mode is selected, and the user can choose one of four states (e.g., read, output disable, standby, or write) depending on inputs to the CE, OE, and WE pins. Table 13 shows assignment states of control input and each state.

#### ● Read

The microcomputer enters the read state by driving the  $\overline{\text{CE}}$ , and  $\overline{\text{OE}}$  pins low and the  $\overline{\text{WE}}$  pin high; and the contents of memory corresponding to the address to be input to address input pins (A<sub>0</sub>–A<sub>16</sub>) are output to the data input/output pins (D<sub>0</sub>–D<sub>7</sub>).

#### ● Output disable

The microcomputer enters the output disable state by driving the  $\overline{\text{CE}}$  pin low and the  $\overline{\text{WE}}$  and  $\overline{\text{OE}}$  pins high; and the data input/output pins enter the floating state.

#### ● Standby

The microcomputer enters the standby state by driving the  $\overline{\text{CE}}$  pin high. The M38B79FF is placed in a power-down state consuming only a minimal supply current. At this time, the data input/output pins enter the floating state.

#### ● Write

The microcomputer enters the write state by driving the VPP pin high (VPP = VPPH) and then the  $\overline{\text{WE}}$  pin low when the  $\overline{\text{CE}}$  pin is low and the  $\overline{\text{OE}}$  pin is high. In this state, software commands can be input from the data input/output pins, and the user can choose program or erase operation depending on the contents of this software command.

**Table 14 Pin description (flash memory parallel I/O mode)**

Pin	Name	Input /Output	Functions
VCC, VSS	Power supply	—	Supply 5 V $\pm$ 10 % to VCC and 0 V to VSS.
CNVSS	VPP input	Input	Connect to 5 V $\pm$ 10 % in read-only mode, connect to 11.7 V to 12.6 V in read/write mode.
RESET	Reset input	Input	Connect to VSS.
XIN	Clock input	Input	Connect a ceramic resonator between XIN and XOUT.
XOUT	Clock output	Output	
AVSS	Analog supply input	—	Connect to VSS.
VREF	Reference voltage input	Input	Connect to VSS.
P00–P07	Address input (A0–A7)	Input	Port P0 functions as 8-bit address input (A0–A7).
P10–P17	Address input (A8–A15)	Input	Port P1 functions as 8-bit address input (A8–A15).
P20–P27	Data I/O (D0–D7)	I/O	Function as 8-bit data's I/O pins (D0–D7). Connect them to VSS through each resistor of 6.8 k $\Omega$ .
P30–P37	Control signal input	Input	P37, P36 and P33 function as the $\overline{OE}$ , $\overline{CE}$ and $\overline{WE}$ input pins respectively. P31 functions as the A16 input pin. Connect P30 and P32 to VSS. Input "H" or "L" to P34, P35, or keep them open.
P40–P47	Input port P4	Input	Input "H" or "L", or keep them open.
P50–P57	Input port P5	Input	Input "H" or "L", or keep them open.
P60–P67	Input port P6	Input	Connect P64 and P66 to VSS. Input "H" or "L" to P60–P63, P65, P67, or keep them open.
P70–P77	Input port P7	Input	Input "H" or "L", or keep them open.
P80–P83	Input port P8	Input	Input "H" or "L", or keep them open.
P90–P97	Input port P9	Input	Input "H" or "L", or keep them open.
PA0–PA7	Input port PA	Input	Input "H" or "L", or keep them open.
PB0–PB6	Input port PB	Input	Input "H" or "L", or keep them open.
VEE	Pull-down power supply		Keep this open.

## FUNCTIONAL DESCRIPTION

Fig. 85 Pin connection of M38B79FF when operating in parallel input/output mode

### Read-only Mode

The microcomputer enters the read-only mode by applying  $V_{PPL}$  to the VPP pin. In this mode, the user can input the address of a memory location to be read and the control signals at the timing

shown in Figure 86, and the M38B79FF will output the contents of the user's specified address from data I/O pin to the external. In this mode, the user cannot perform any operation other than read.

Fig. 86 Read timing

### Read/Write Mode

The microcomputer enters the read/write mode by applying  $V_{PPH}$  to the VPP pin. In this mode, the user must first input a software command to choose the operation (e. g., read, program, or erase) to be performed on the flash memory (this is called the first cycle), and then input the information necessary for execution of the command (e.g. address and data) and control signals (this is called the second cycle). When this is done, the M38B79FF executes the specified operation.

Table 15 shows the software commands and the input/output information in the first and the second cycles. The input address is latched internally at the falling edge of the  $\overline{WE}$  input; software commands and other input data are latched internally at the rising edge of the  $\overline{WE}$  input.

The following explains each software command. Refer to Figures 87 to 89 for details about the signal input/output timings.

Table 15 Software command (parallel input/output mode)

Symbol	First cycle		Second cycle	
	Address input	Data input	Address input	Data I/O
Read	×	00 <sub>16</sub>	Read address	Read data (Output)
Program	×	40 <sub>16</sub>	Program address	Program data (Input)
Program verify	×	C0 <sub>16</sub>	×	Verify data (Output)
Erase	×	20 <sub>16</sub>	×	20 <sub>16</sub> (Input)
Erase verify	Verify address	A0 <sub>16</sub>	×	Verify data (Output)
Reset	×	FF <sub>16</sub>	×	FF <sub>16</sub> (Input)
Device identification	×	90 <sub>16</sub>	ADI	DDI (Output)

**Note:** ADI = Device identification address : manufacturer's code 00000<sub>16</sub>, device code 00001<sub>16</sub>

DDI = Device identification data : manufacturer's code 1C<sub>16</sub>, device code D0<sub>16</sub>

× can be VIL or VIH.

# HARDWARE

## FUNCTIONAL DESCRIPTION

### ● Read command

The microcomputer enters the read mode by inputting command code "0016" in the first cycle. The command code is latched into the internal command latch at the rising edge of the  $\overline{WE}$  input. When the address of a memory location to be read is input in the second cycle, with control signals input at the timing shown in Figure 87, the M38B79FF outputs the contents of the specified address from the data I/O pins to the external.

The read mode is retained until any other command is latched into the command latch. Consequently, once the M38B79FF enters the read mode, the user can read out the successive memory contents simply by changing the input address and executing the second cycle only. Any command other than the read command must be input beginning from its command code over again each time the user execute it. The contents of the command latch immediately after power-on is 0016.

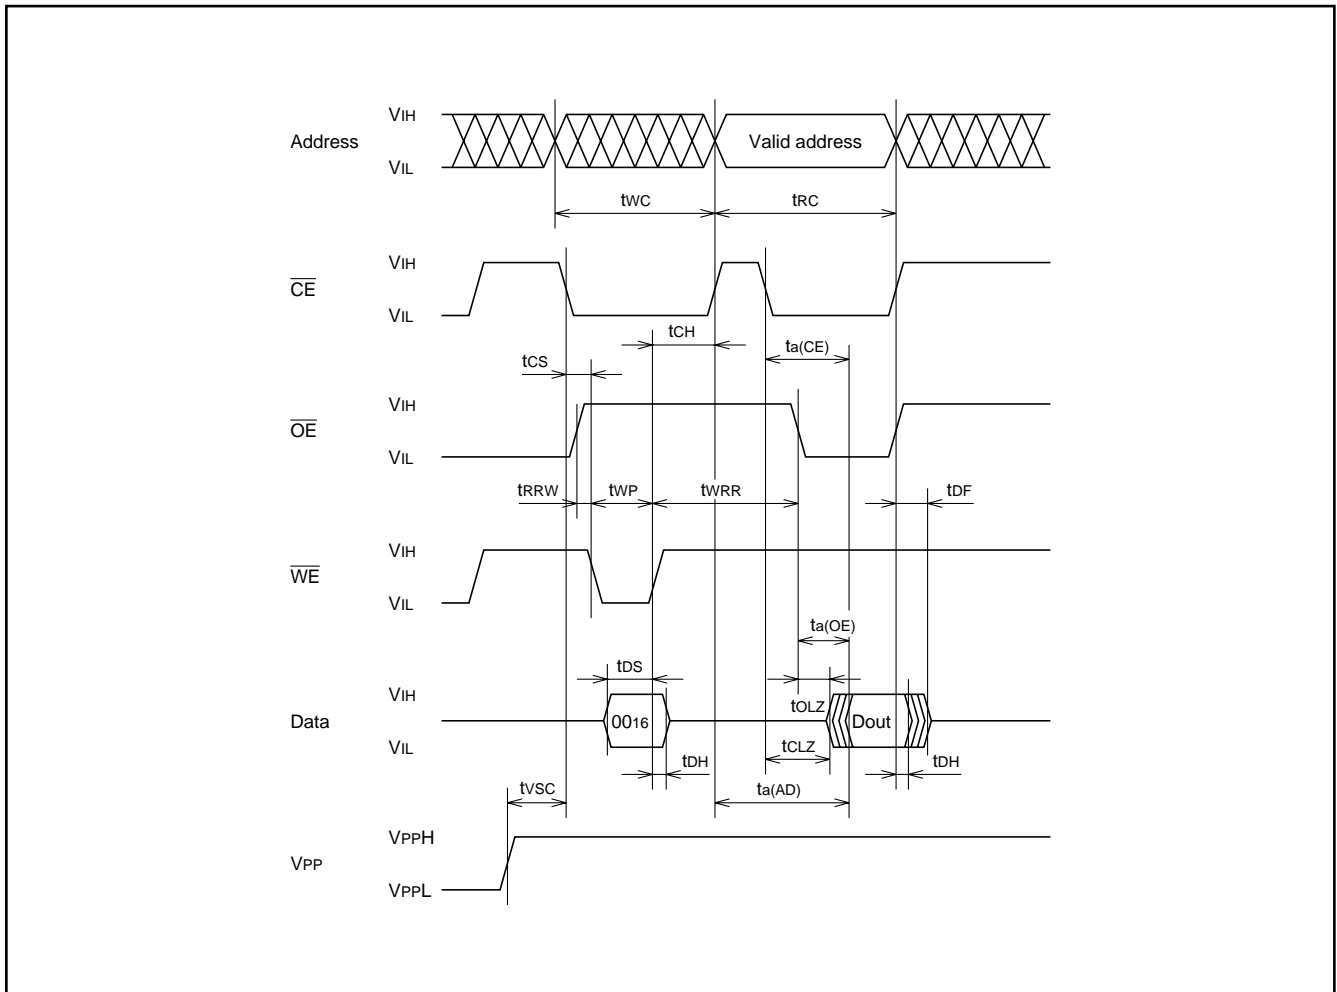

Fig. 87 Timings during reading

### ● Program command

The microcomputer enters the program mode by inputting command code "4016" in the first cycle. The command code is latched into the internal command latch at the rising edge of the  $\overline{WE}$  input. When the address which indicates a program location and data is input in the second cycle, the M38B79FF internally latches the address at the falling edge of the  $\overline{WE}$  input and the data at the rising edge of the  $\overline{WE}$  input. The M38B79FF starts programming at the rising edge of the  $\overline{WE}$  input in the second cycle and finishes programming within 10  $\mu\text{s}$  as measured by its internal timer. Programming is performed in units of bytes.

**Note:** A programming operation is not completed by executing the program command once. Always be sure to execute a program verify command after executing the program command. When the failure is found in this verification, the user must repeatedly execute the program command until the pass. Refer to Figure 90 for the programming flowchart.

### ● Program verify command

The microcomputer enters the program verify mode by inputting command code "C016" in the first cycle. This command is used to verify the programmed data after executing the program command. The command code is latched into the internal command latch at the rising edge of the  $\overline{WE}$  input. When control signals are input in the second cycle at the timing shown in Figure 88, the M38B79FF outputs the programmed address's contents to the external. Since the address is internally latched when the program command is executed, there is no need to input it in the second cycle.

Fig. 88 Input/output timings during programming (Verify data is output at the same timing as for read.)

# HARDWARE

## FUNCTIONAL DESCRIPTION

### ● Erase command

The erase command is executed by inputting command code 20<sub>16</sub> in the first cycle and command code 20<sub>16</sub> again in the second cycle. The command code is latched into the internal command latch at the rising edges of the  $\overline{WE}$  input in the first cycle and in the second cycle, respectively. The erase operation is initiated at the rising edge of the  $\overline{WE}$  input in the second cycle, and the memory contents are collectively erased within 9.5 ms as measured by the internal timer. Note that data 00<sub>16</sub> must be written to all memory locations before executing the erase command.

**Note:** An erase operation is not completed by executing the erase command once. Always be sure to execute an erase verify command after executing the erase command. When the failure is found in this verification, the user must repeatedly execute the erase command until the pass. Refer to Figure 90 for the erase flowchart.

### ● Erase verify command

The user must verify the contents of all addresses after completing the erase command. The microcomputer enters the erase verify mode by inputting the verify address and command code A0<sub>16</sub> in the first cycle. The address is internally latched at the falling edge of the  $\overline{WE}$  input, and the command code is internally latched at the rising edge of the  $\overline{WE}$  input. When control signals are input in the second cycle at the timing shown in Figure 89, the M38B79FF outputs the contents of the specified address to the external.

**Note:** If any memory location where the contents have not been erased is found in the erase verify operation, execute the operation of “erase → erase verify” over again. In this case, however, the user does not need to write data 00<sub>16</sub> to memory locations before erasing.

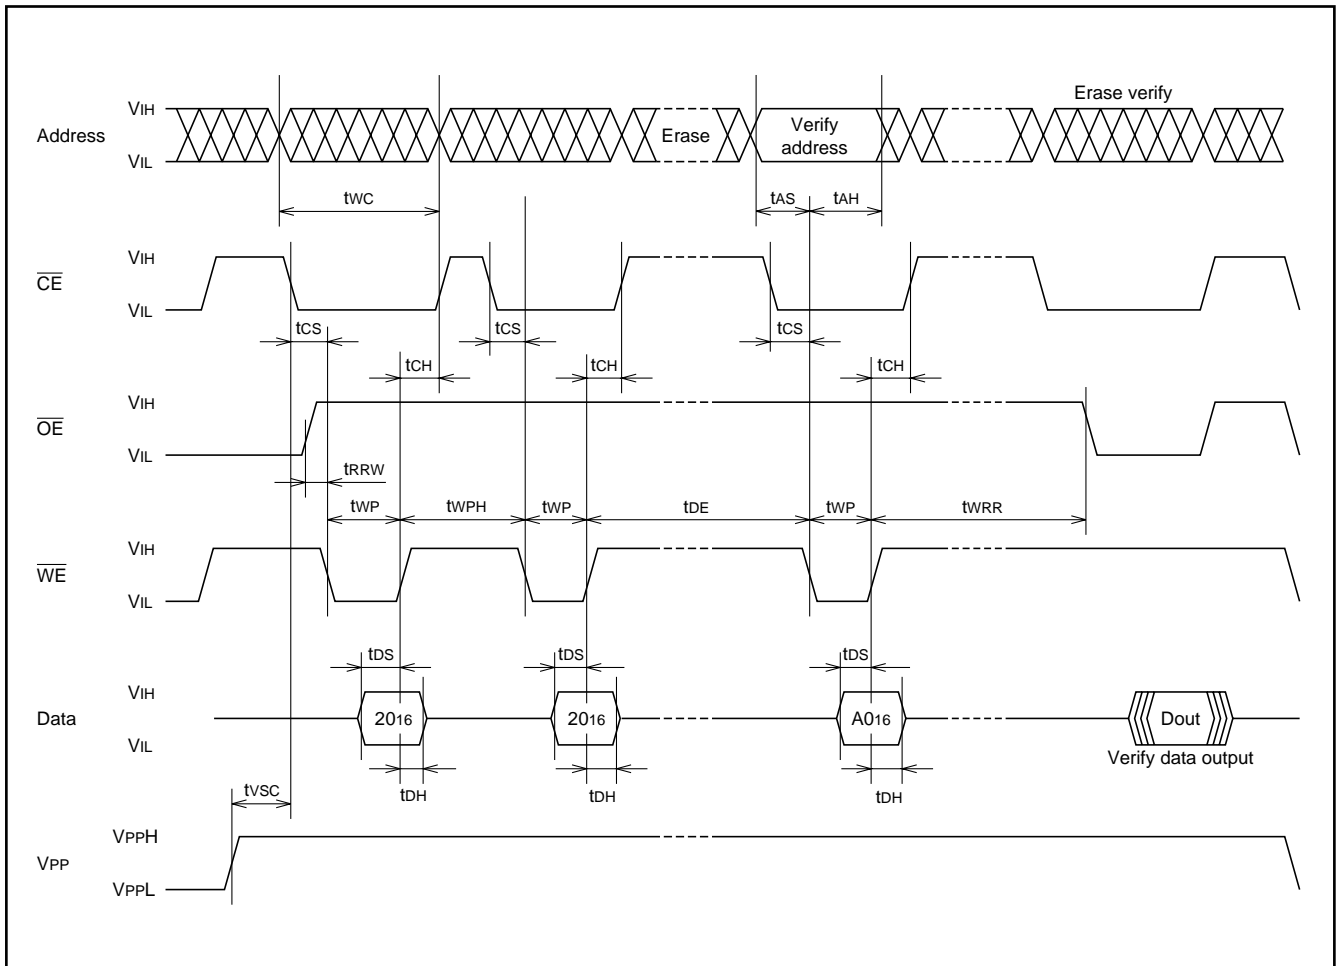

Fig. 89 Input/output timings during erasing (verify data is output at the same timing as for read.)

### ● Reset command

The reset command provides a means of stopping execution of the erase or program command safely. If the user inputs command code FF<sub>16</sub> in the second cycle after inputting the erase or program command in the first cycle and again input command code FF<sub>16</sub> in the third cycle, the erase or program command is disabled (i.e., reset), and the M38B79FF is placed in the read mode. If the reset command is executed, the contents of the memory does not change.

### ● Device identification code command

By inputting command code 90<sub>16</sub> in the first cycle, the user can read out the device identification code. The command code is latched into the internal command latch at the rising edge of the  $\overline{WE}$  input. At this time, the user can read out manufacture's code 1C<sub>16</sub> (i.e., MITSUBISHI) by inputting 0000<sub>16</sub> to the address input pins in the second cycle; the user can read out device code D0<sub>16</sub> (i. e., 1M-bit flash memory) by inputting 0001<sub>16</sub>.

These command and data codes are input/output at the same timing as for read.

# HARDWARE

## FUNCTIONAL DESCRIPTION

### (2) Flash memory mode 2 (serial I/O mode)

The M38B79FF has a function to serially input/output the software commands, addresses, and data required for operation on the internal flash memory (e. g., read, program, and erase) using only a few pins. This is called the serial I/O (input/output) mode. This mode can be selected by driving the SDA (serial data input/output), SCLK (serial clock input), and  $\overline{OE}$  pins high after connecting

wires as shown in Figures 91 and powering on the VCC pin and then applying VPPH to the VPP pin.

In the serial I/O mode, the user can use six types of software commands: read, program, program verify, erase, erase verify and error check.

Serial input/output is accomplished synchronously with the clock, beginning from the LSB (LSB first).

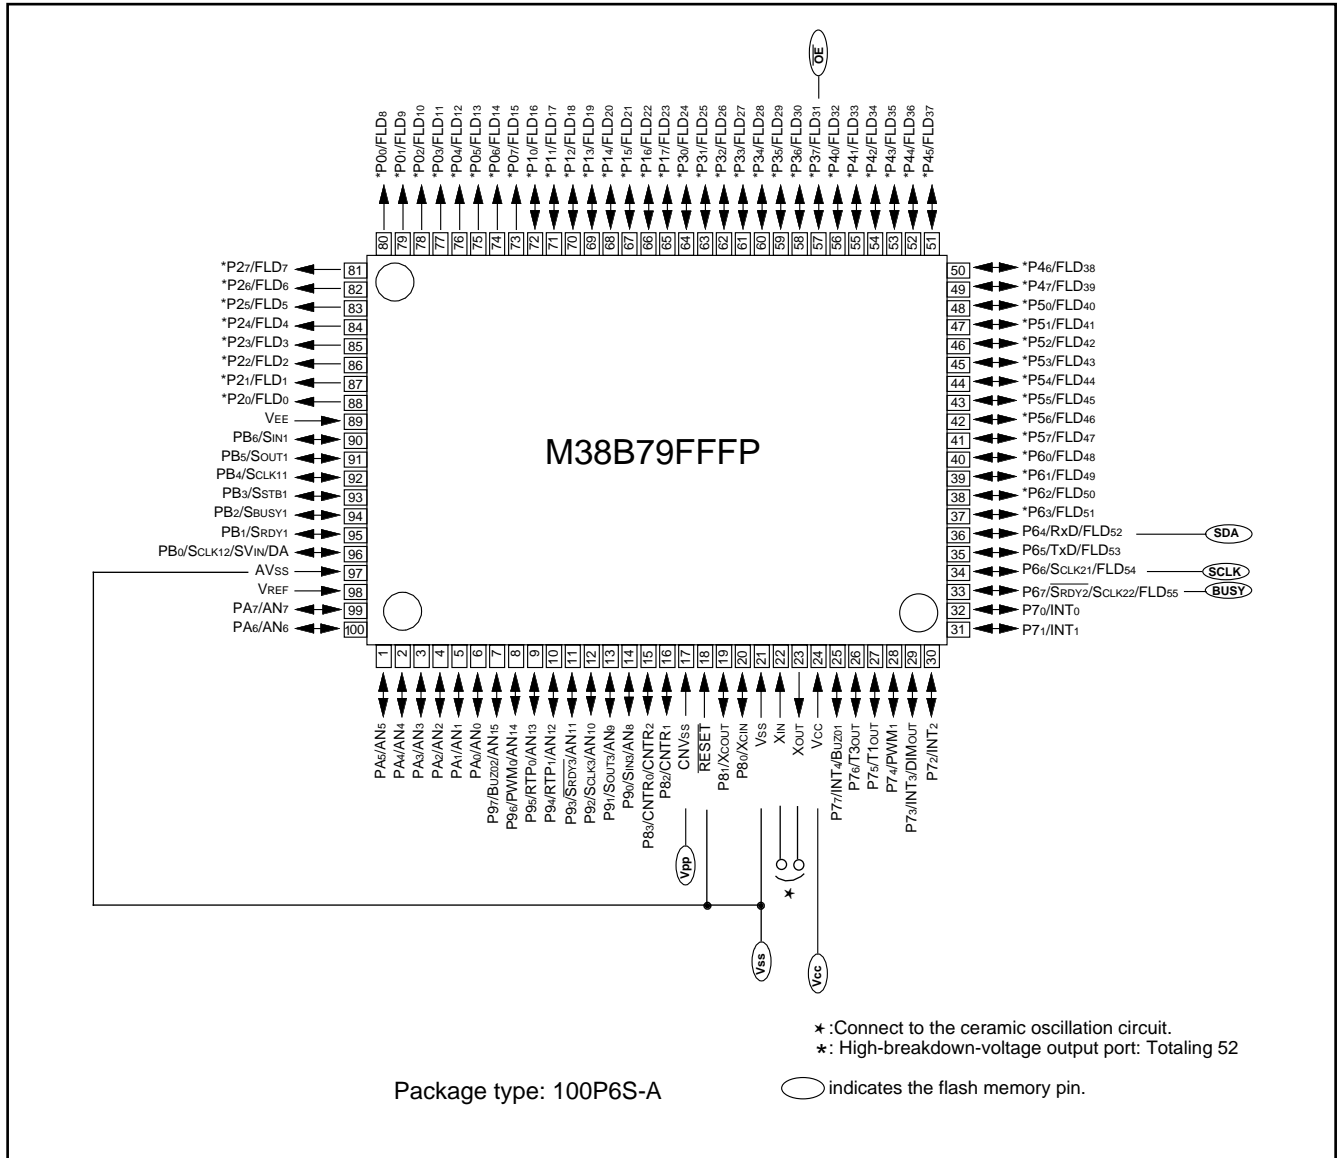

Fig. 91 Pin connection of M38B79FF when operating in serial I/O mode

VEE	Pull-down power supply		Keep this open.

# HARDWARE

## FUNCTIONAL DESCRIPTION

### Functional Outline (serial I/O mode)

In the serial I/O mode, data is transferred synchronously with the clock using serial input/output. The input data is read from the SDA pin into the internal circuit synchronously with the rising edge of the serial clock pulse; the output data is output from the SDA pin synchronously with the falling edge of the serial clock pulse.

Data is transferred in units of eight bits.

In the first transfer, the user inputs the command code. This is followed by address input and data input/output according to the contents of the command. Table 20 shows the software commands used in the serial I/O mode. The following explains each software command.

**Table 20 Software command (serial I/O mode)**

Command	Number of transfers	First command code input	Second	Third	Fourth
Read		00 <sub>16</sub>	Read address L (Input)	Read address H (Input)	Read data (Output)
Program		40 <sub>16</sub>	Program address L (Input)	Program address H (Input)	Program data (Input)
Program verify		C0 <sub>16</sub>	Verify data (Output)	_____	_____
Erase		20 <sub>16</sub>	20 <sub>16</sub> (Input)	_____	_____
Erase verify		A0 <sub>16</sub>	Verify address L (Input)	Verify address H (Input)	Verify data (Output)
Error check		80 <sub>16</sub>	Error code (Output)	_____	_____

### ● Read command

Input command code 00<sub>16</sub> in the first transfer. Proceed and input the low-order 8 bits and the high-order 8 bits of the address and pull the  $\overline{OE}$  pin low. When this is done, the M38B79FF reads out the contents of the specified address, and then latches it into the in-

ternal data latch. When the  $\overline{OE}$  pin is released back high and serial clock is input to the SCLK pin, the read data that has been latched into the data latch is serially output from the SDA pin.

**Fig. 92 Timings during reading**

### ● Program command

Input command code 40<sub>16</sub> in the first transfer. Proceed and input the low-order 8 bits and the high-order 8 bits of the address and then program data. Programming is initiated at the last rising edge of the serial clock during program data transfer. The BUSY pin is driven high during program operation. Programming is completed within 10  $\mu$ s as measured by the internal timer, and the BUSY pin is pulled low.

**Note :** A programming operation is not completed by executing the program command once. Always be sure to execute a program verify command after executing the program command. When the failure is found in the verification, the user must repeatedly execute the program command until the pass in the verification. Refer to Figure 90 for the programming flowchart.

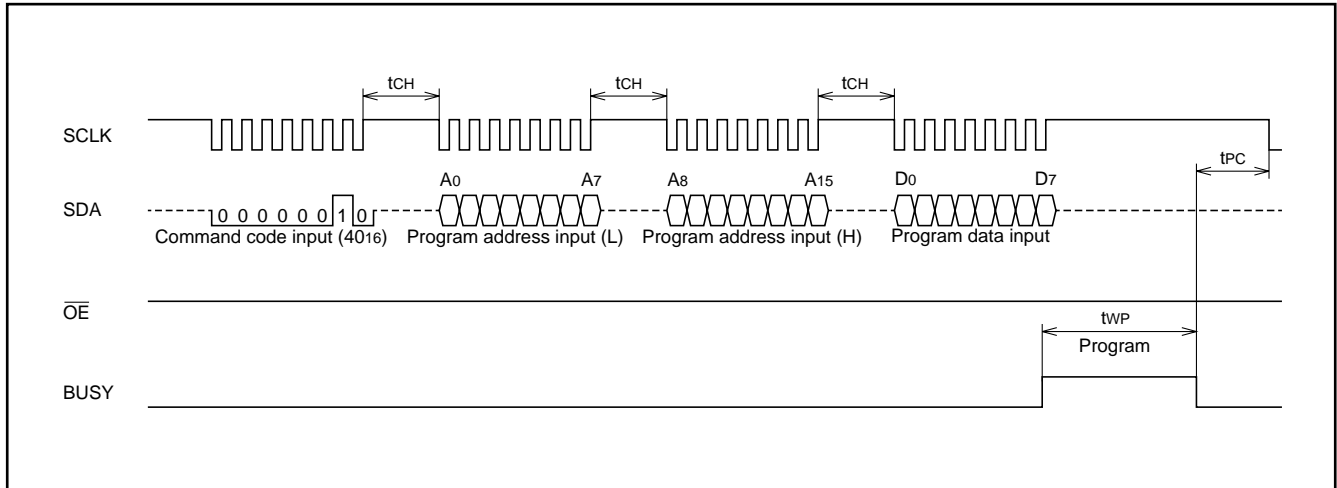

Fig. 93 Timings during programming

### ● Program verify command

Input command code C0<sub>16</sub> in the first transfer. Proceed and drive the OE pin low. When this is done, The M38B79FF verify-reads the programmed address's contents, and then latches it into the in-

ternal data latch. When the OE pin is released back high and serial clock is input to the SCLK pin, the verify data that has been latched into the data latch is serially output from the SDA pin.

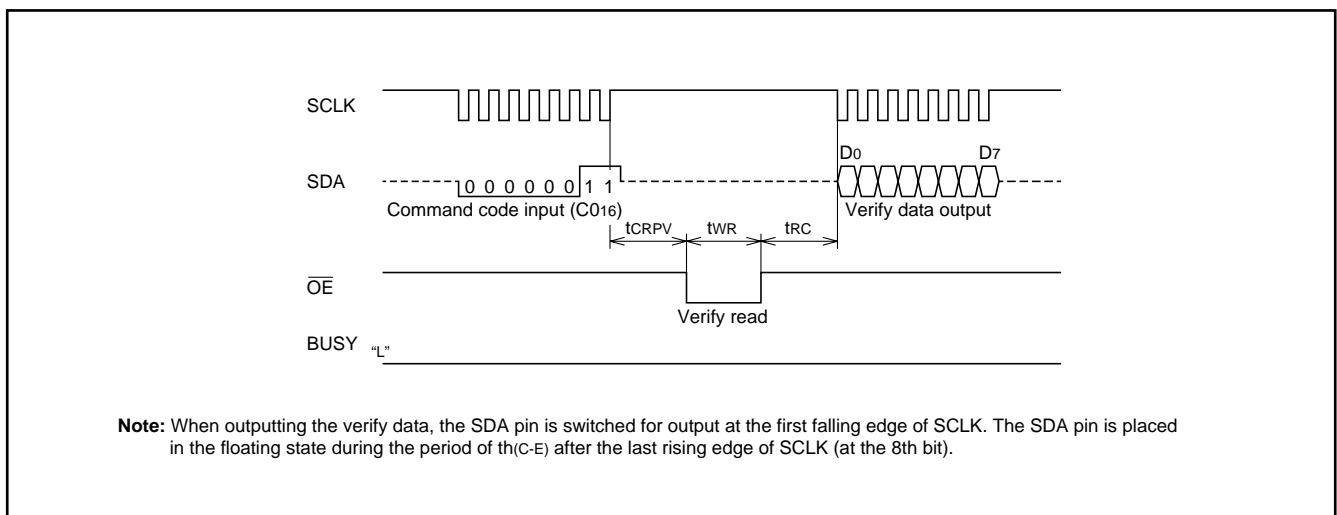

Fig. 94 Timings during program verify

# HARDWARE

## FUNCTIONAL DESCRIPTION

### ● Erase command

Input command code 20<sub>16</sub> in the first transfer and command code 20<sub>16</sub> again in the second transfer. When this is done, the M38B79FF executes an erase command. Erase is initiated at the last rising edge of the serial clock. The BUSY pin is driven high during the erase operation. Erase is completed within 9.5 ms as measured by the internal timer, and the BUSY pin is pulled low. Note that data 00<sub>16</sub> must be written to all memory locations before

executing the erase command.

**Note:** A erase operation is not completed by executing the erase command once. Always be sure to execute a erase verify command after executing the erase command. When the failure is found in the verification, the user must repeatedly execute the erase command until the pass in the verification. Refer to Figure 90 for the erase flowchart.

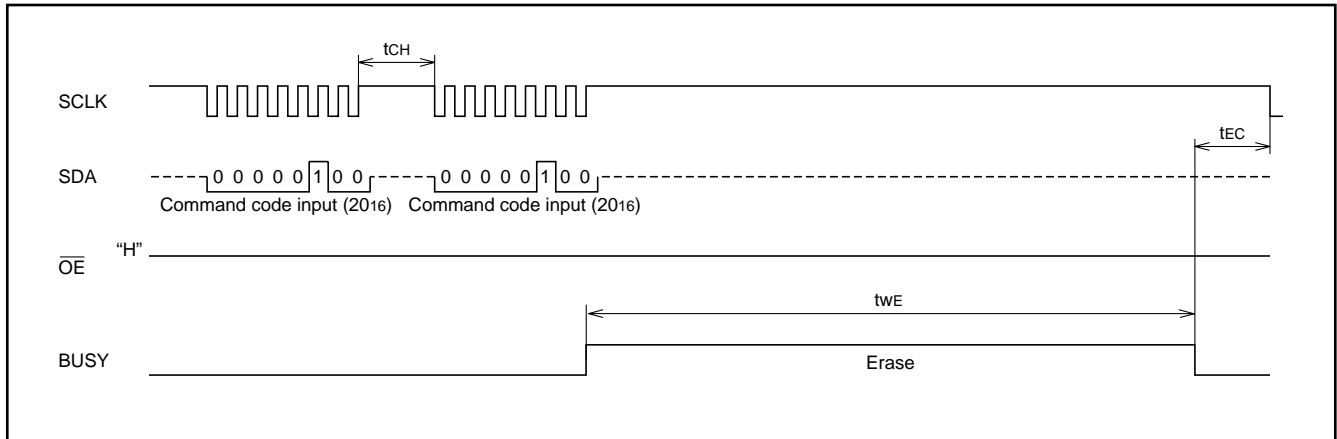

Fig. 95 Timings at erasing

### ● Erase verify command

The user must verify the contents of all addresses after completing the erase command. Input command code A0<sub>16</sub> in the first transfer. Proceed and input the low-order 8 bits and the high-order 8 bits of the address and pull the OE pin low. When this is done, the M38B79FF reads out the contents of the specified address, and then latches it into the internal data latch. When the OE pin is released back high and serial clock is input to the SCLK pin, the

verify data that has been latched into the data latch is serially output from the SDA pin.

**Note:** If any memory location where the contents have not been erased is found in the erase verify operation, execute the operation of “erase → erase verify” over again. In this case, however, the user does not need to write data 00<sub>16</sub> to memory locations before erasing.

**Note :** When outputting the verify data, the SDA pin is switched for output at the first falling edge of SCLK. The SDA pin is placed in the floating state during the period of th(C-E) after the last rising edge of SCLK (at the 8th bit).

Fig. 96 Timings during erase verify

### ● Error check command

Input command code 80<sub>16</sub> in the first transfer, and the M38B79FF outputs error information from the SDA pin, beginning at the next falling edge of the serial clock. If the LSB bit of the 8-bit error information is 1, it indicates that a command error has occurred. A command error means that some invalid commands other than commands shown in Table 20 has been input.

When a command error occurs, the serial communication circuit sets the corresponding flag and stops functioning to avoid an erroneous programming or erase. When being placed in this state, the serial communication circuit does not accept the subsequent serial clock and data (even including an error check command). Therefore, if the user wants to execute an error check command,

temporarily drop the VPP pin input to the VPPL level to terminate the serial input/output mode. Then, place the M38B79FF into the serial I/O mode back again. The serial communication circuit is reset by this operation and is ready to accept commands. The error flag alone is not cleared by this operation, so the user can examine the serial communication circuit's error conditions before reset. This examination is done by the first execution of an error check command after the reset. The error flag is cleared when the user has executed the error check command. Because the error flag is undefined immediately after power-on, always be sure to execute the error check command.

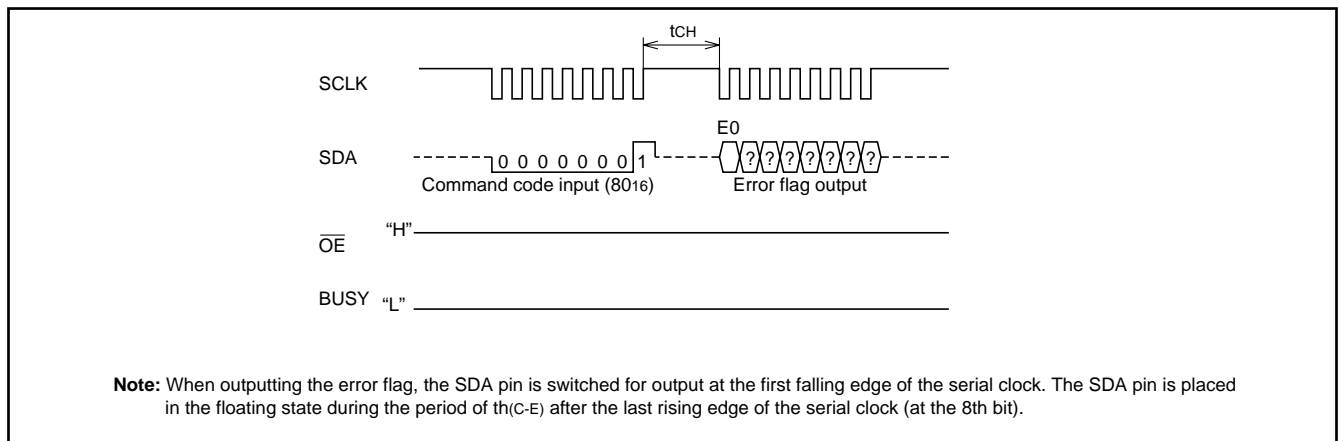

Fig. 97 Timings at error checking

# HARDWARE

## FUNCTIONAL DESCRIPTION

### DC ELECTRICAL CHARACTERISTICS (Ta = 25 °C, Vcc = 5 V ± 10 %, Vpp = 11.7 to 12.6 V, unless otherwise noted)

ICC, IPP-relevant standards during read, program, and erase are the same as in the parallel input/output mode. VIH, VIL, VOH, VOL, IIH, and IIL for the SCLK, SDA, BUSY, OE pins conform to the microcomputer modes.

**Table 21 AC Electrical characteristics**

(Ta = 25 °C, Vcc = 5 V ± 10 %, Vpp = 11.7 to 12.6 V, f(XIN) = 4 MHz, unless otherwise noted)

Symbol	Parameter	Limits		Unit
		Min.	Max.	
tCH	Serial transmission interval	625 <sup>(Note 1)</sup>		ns
tCR	Read waiting time after transmission	625 <sup>(Note 1)</sup>		ns
tWR	Read pulse width	500 <sup>(Note 2)</sup>		ns
tRC	Transfer waiting time after read	625 <sup>(Note 1)</sup>		ns
tCRPV	Waiting time before program verify	6		µs
tWP	Programming time		10	µs
tPC	Transfer waiting time after programming	625 <sup>(Note 1)</sup>		ns
tCREV	Waiting time before erase verify	6		µs
tWE	Erase time		9.5	ms
tEC	Transfer waiting time after erase	625 <sup>(Note 1)</sup>		ns
tc(CK)	SCLK input cycle time	250		ns
tw(CKH)	SCLK high-level pulse width	100		ns
tw(CKL)	SCLK low-level pulse width	100		ns
tr(CK)	SCLK rise time	20		ns

th(C-D)	SDA input hold time	90		ns

**Notes 1:** When f(XIN) = 4 MHz or less, calculate the minimum value according to formula 1.

$$\text{Formula 1 : } \frac{2500}{f(XIN)} \times 10^6$$

**2:** When f(XIN) = 4 MHz or less, calculate the minimum value according to formula 2.

$$\text{Formula 2 : } \frac{2000}{f(XIN)} \times 10^6$$

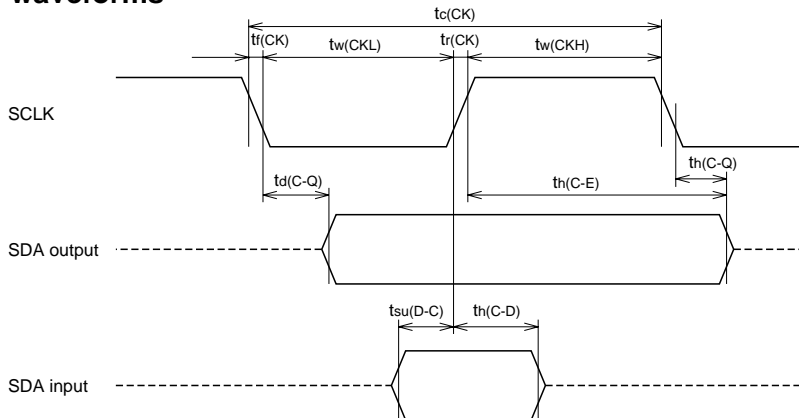

**3:** When f(XIN) = 4 MHz or less, calculate the minimum value according to formula 3.

$$\text{Formula 3 : } \frac{750}{f(XIN)} \times 10^6$$

**4:** When f(XIN) = 4 MHz or less, calculate the minimum value according to formula 4

$$\text{Formula 4 : } \frac{1250}{f(XIN)} \times 10^6$$

### AC waveforms

Test conditions for AC characteristics

- Output timing voltage : VOL = 0.8 V, VOH = 2.0 V
- Input timing voltage : VIL = 0.2 Vcc, VIH = 0.8 Vcc

### (3) Flash memory mode 3 (CPU reprogramming mode)

The M38B79FF has the CPU reprogramming mode where a built-in flash memory is handled by the central processing unit (CPU). In CPU reprogramming mode, the flash memory is handled by writing and reading to/from the flash memory control register (see Figure 98) and the flash command register (see Figure 99). The CNVSS pin is used as the VPP power supply pin in CPU reprogramming mode. It is necessary to apply the power-supply voltage of VPPH from the external to this pin.

#### Functional Outline (CPU reprogramming mode)

Figure 98 shows the flash memory control register bit configuration. Figure 99 shows the flash command register bit configuration.

Bit 0 of the flash memory control register is the CPU reprogramming mode select bit. When this bit is set to "1" and VPPH is applied to the CNVSS/VPP pin, the CPU reprogramming mode is selected. Whether the CPU reprogramming mode is realized or not is judged by reading the CPU reprogramming mode monitor flag (bit 2 of the flash memory control register).

Bit 1 is a busy flag which becomes "1" during erase and program execution.

Whether these operations have been completed or not is judged

by checking this flag after each command of erase and the program is executed.

Bits 4, 5 of the flash memory control register are the erase/program area select bits. These bits specify an area where erase and program is operated. When the erase command is executed after an area is specified by these bits, only the specified area is erased. Only for the specified area, programming is enabled; for the other areas, programming is disabled.

Figure 100 shows the CPU mode register bit configuration in the CPU reprogramming mode.

Fig. 98 Flash memory control register bit configuration

# HARDWARE

## FUNCTIONAL DESCRIPTION

### ● CPU reprogramming mode operation procedure

The operation procedure in CPU reprogramming mode is described below.

< Beginning procedure >

- ① Apply 0 V to the CNVss/VPP pin for reset release.
- ② Set the CPU mode register. (see Figure 100)
- ③ After CPU reprogramming mode control program is transferred to internal RAM, jump to this control program on RAM. (The following operations are controlled by this control program).
- ④ Set "1" to the CPU reprogramming mode select bit.
- ⑤ Apply VPPH to the CNVSS/VPP pin.
- ⑥ Wait till CNVSS/VPP pin becomes 12 V.
- ⑦ Read the CPU reprogramming mode monitor flag to confirm whether the CPU reprogramming mode is valid.
- ⑧ The operation of the flash memory is executed by software-command-writing to the flash command register .

**Note:** The following are necessary other than this:

- Control for data which is input from the external (serial I/O etc.) and to be programmed to the flash memory
- Initial setting for ports etc.
- Writing to the watchdog timer

< Release procedure >

- ① Apply 0V to the CNVss/VPP pin.
- ② Wait till CNVss/VPP pin becomes 0V.
- ③ Set the CPU reprogramming mode select bit to "0".

Each software command is explained as follows.

### ● Read command

When "0016" is written to the flash command register, the M38B79FF enters the read mode. The contents of the corresponding address can be read by reading the flash memory (For instance, with the LDA instruction etc.) under this condition.

The read mode is maintained until another command code is written to the flash command register. Accordingly, after setting the read mode once, the contents of the flash memory can continuously be read.

After reset and after the reset command is executed, the read mode is set.

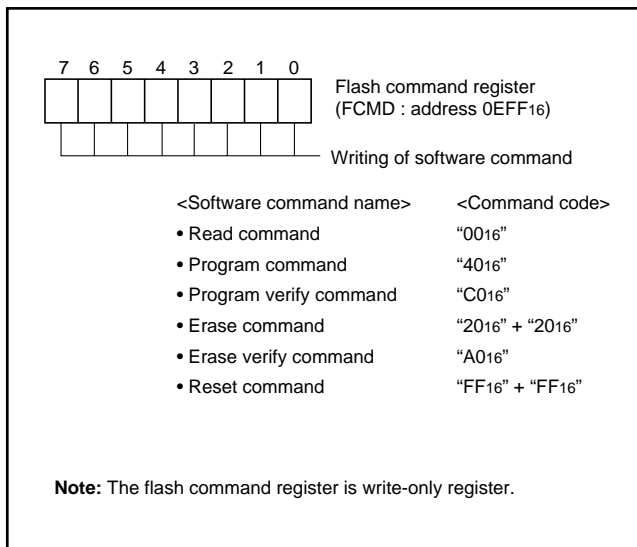

Fig. 99 Flash command register bit configuration

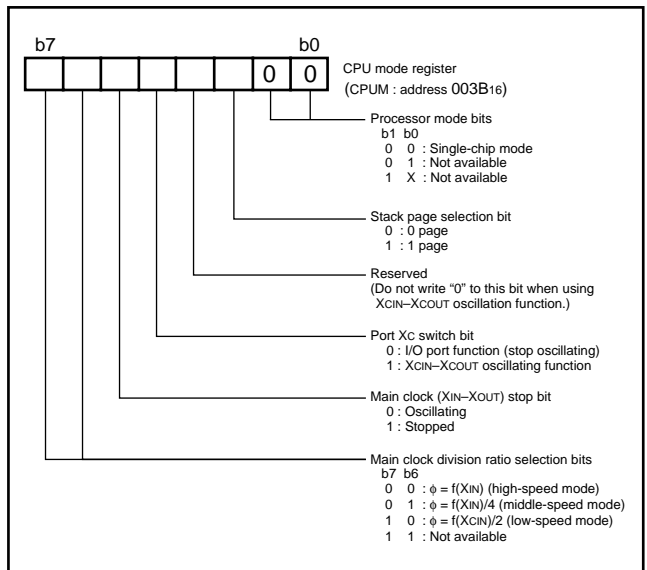

Fig. 100 CPU mode register bit configuration in CPU rewriting mode

### ● Program command

When "40<sub>16</sub>" is written to the flash command register, the M38B79FF enters the program mode.

Subsequently to this, if the instruction (for instance, STA instruction) for writing byte data in the address to be programmed is executed, the control circuit of the flash memory executes the program. The erase/program busy flag of the flash memory control register is set to "1" when the program starts, and becomes "0" when the program is completed. Accordingly, after the write instruction is executed, CPU can recognize the completion of the program by polling this bit.

The programmed area must be specified beforehand by the erase/program area select bits.

During programming, watchdog timer stops with "FFFF<sub>16</sub>" set.

**Note:** A programming operation is not completed by executing the program command once. Always be sure to execute a program verify command after executing the program command. When the failure is found in this verification, the user must repeatedly execute the program command until the pass. Refer to Figure 101 for the flow chart of the programming.

### ● Program verify command

When "C0<sub>16</sub>" is written to the flash command register, the M38B79FF enters the program verify mode. Subsequently to this, if the instruction (for instance, LDA instruction) for reading byte data from the address to be verified (i.e., previously programmed address), the contents which has been written to the address actually is read.

CPU compares this read data with data which has been written by the previous program command. In consequence of the comparison, if not agreeing, the operation of "program → program verify" must be executed again.

### ● Erase command

When writing "20<sub>16</sub>" twice continuously to the flash command register, the flash memory control circuit performs erase to the area specified beforehand by the erase/program area select bits.

Erase/program busy flag of the flash memory control register becomes "1" when erase begins, and it becomes "0" when erase completes. Accordingly, CPU can recognize the completion of erase by polling this bit.

Data "00<sub>16</sub>" must be written to all areas to be erased by the program and the program verify commands before the erase command is executed.

During erasing, watchdog timer stops with "FFFF<sub>16</sub>" set.

**Note:** The erasing operation is not completed by executing the erase command once. Always be sure to execute an erase verify command after executing the erase command. When the failure is found in this verification, the user must repeatedly execute the erase command until the pass. Refer to Figure 101 for the erasing flowchart.

### ● Erase verify command

When "A0<sub>16</sub>" is written to the flash command register, the M38B79FF enters the erase verify mode. Subsequently to this, if the instruction (for instance, LDA instruction) for reading byte data from the address to be verified, the contents of the address is read.

CPU must erase and verify to all erased areas in a unit of address.

If the address of which data is not "FF<sub>16</sub>" (i.e., data is not erased) is found, it is necessary to discontinue erasure verification there, and execute the operation of "erase → erase verify" again.

**Note:** By executing the operation of "erase → erase verify" again when the memory not erased is found. It is unnecessary to write data "00<sub>16</sub>" before erasing in this case.

### ● Reset command

The reset command is a command to discontinue the program or erase command on the way. When "FF<sub>16</sub>" is written to the command register two times continuously after "40<sub>16</sub>" or "20<sub>16</sub>" is written to the flash command register, the program, or erase command becomes invalid (reset), and the M38B79FF enters the reset mode.

The contents of the memory does not change even if the reset command is executed.

## DC Electric Characteristics

**Note:** The characteristic concerning the flash memory part are the same as the characteristic of the parallel I/O mode.

## AC Electric Characteristics

**Note:** The characteristics are the same as the characteristic of the microcomputer mode.

# HARDWARE

## FUNCTIONAL DESCRIPTION

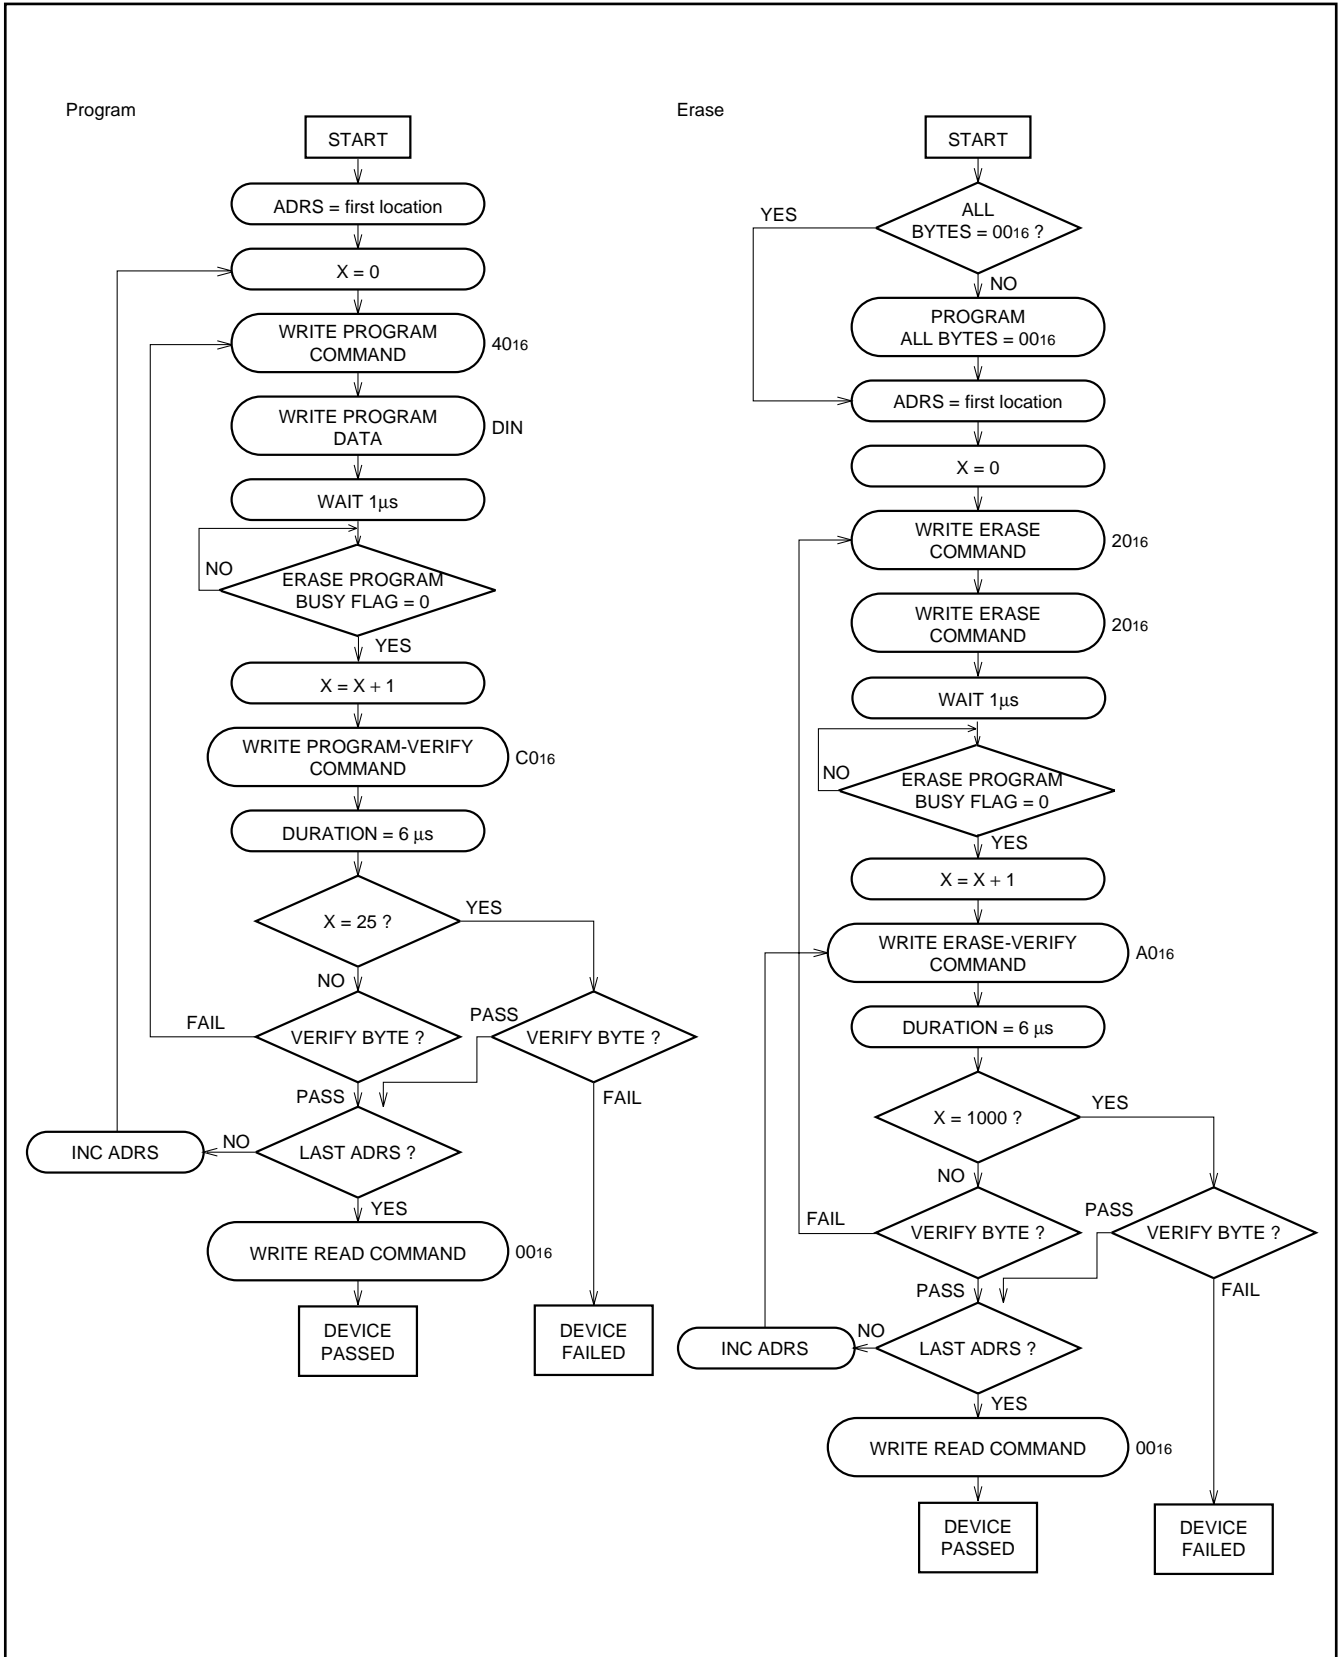

Fig. 101 Flowchart of program/erase operation at CPU reprogramming mode

### NOTES ON PROGRAMMING

#### Processor Status Register

The contents of the processor status register (PS) after a reset are undefined, except for the interrupt disable flag (I) which is "1." After a reset, initialize flags which affect program execution. In particular, it is essential to initialize the index X mode (T) and the decimal mode (D) flags because of their effect on calculations.

#### Interrupts

The contents of the interrupt request bits do not change immediately after they have been written. After writing to an interrupt request register, execute at least one instruction before performing a BBC or BBS instruction.

#### Decimal Calculations

- To calculate in decimal notation, set the decimal mode flag (D) to "1", then execute an ADC or SBC instruction. After executing an ADC or SBC instruction, execute at least one instruction before executing a SEC, CLC, or CLD instruction.
- In decimal mode, the values of the negative (N), overflow (V), and zero (Z) flags are invalid.

#### Timers

If a value  $n$  (between 0 and 255) is written to a timer latch, the frequency division ratio is  $1/(n+1)$ .

#### Multiplication and Division Instructions

- The index X mode (T) and the decimal mode (D) flags do not affect the MUL and DIV instruction.
- The execution of these instructions does not change the contents of the processor status register.

#### Ports

The contents of the port direction registers cannot be read. The following cannot be used:

- The data transfer instruction (LDA, etc.)
- The operation instruction when the index X mode flag (T) is "1"
- The instruction with the addressing mode which uses the value of a direction register as an index
- The bit-test instruction (BBC or BBS, etc.) to a direction register
- The read-modify-write instructions (ROR, CLB, or SEB, etc.) to a direction register.

Use instructions such as LDM and STA, etc., to set the port direction registers.

#### Serial I/O

##### •Using an external clock

When using an external clock, input "H" to the external clock input pin and clear the serial I/O interrupt request bit before executing serial I/O transfer and serial I/O automatic transfer.

##### •Using an internal clock

When using an internal clock, set the synchronous clock to the internal clock, then clear the serial I/O interrupt request bit before executing serial I/O transfer and serial I/O automatic transfer.

#### Automatic Transfer Serial I/O

When using the automatic transfer serial I/O mode of the serial I/O1, set an automatic transfer interval as the following.

Otherwise the serial data might be incorrectly transmitted/received.

- Set an automatic transfer interval for each 1-byte data transfer as the following:

(1) Not using FLD controller

Keep the interval for **5 cycles or more of internal system clock** from clock rising of the last bit of 1-byte data.

(2) Using FLD controller

(a) Not using gradation display

Keep the interval for **17 cycles or more of internal system clock** from clock rising of the last bit of 1-byte data.

(b) Using gradation display

Keep the interval for **27 cycles or more of internal system clock** from clock rising of the last bit of 1-byte data.

#### A-D Converter

The comparator uses capacitive coupling amplifier whose charge will be lost if the clock frequency is too low.

Therefore, make sure that  $f(X_{IN})$  is at least on 250 kHz during an A-D conversion.

Do not execute the STP or WIT instruction during an A-D conversion.

#### D-A Converter

The accuracy of the D-A converter becomes rapidly poor under the  $V_{CC} = 4.0$  V or less condition; a supply voltage of  $V_{CC} \geq 4.0$  V is recommended. When a D-A converter is not used, set the value of D-A conversion register to "0016".

#### Instruction Execution Time

The instruction execution time is obtained by multiplying the period of the internal clock  $\phi$  by the number of cycles needed to execute an instruction.

The number of cycles required to execute an instruction is shown in the list of machine instructions.

The period of the internal clock  $\phi$  is half of the  $X_{IN}$  period in high-speed mode.

# HARDWARE

## NOTES ON USAGE/ DATA REQUIRED FOR MASK ORDERS

---

### NOTES ON USAGE

#### Handling of Power Source Pins

In order to avoid a latch-up occurrence, connect a capacitor suitable for high frequencies as bypass capacitor between power source pin (VCC pin) and GND pin (VSS pin), between power source pin (VCC pin) and analog power source input pin (AVSS pin), and between program power source pin (CNVSS/VPP) and GND pin for flash memory version when on-board reprogramming is executed. Besides, connect the capacitor to as close as possible. For bypass capacitor which should not be located too far from the pins to be connected, a ceramic capacitor of 0.01  $\mu\text{F}$ –0.1  $\mu\text{F}$  is recommended.

#### Flash Memory Version

The CNVSS pin is connected to the internal memory circuit block by a low-ohmic resistance, since it has the multiplexed function to be a programmable power source pin (VPP pin) as well.

To improve the noise reduction, connect a track between CNVSS pin and VSS pin or VCC pin with 1 to 10 k $\Omega$  resistance.

The mask ROM version track of CNVSS pin has no operational interference even if it is connected to VSS pin or VCC pin via a resistor.

#### Electric Characteristic Differences Between Mask ROM and Flash Memory Version MCUs

There are differences in electric characteristics, operation margin, noise immunity, and noise radiation between Mask ROM and Flash Memory version MCUs due to the difference in the manufacturing processes.

When manufacturing an application system with Flash Memory version and then switching to use of Mask ROM version, please perform sufficient evaluations for the commercial samples of Mask ROM version.

### DATA REQUIRED FOR MASK ORDERS

The following are necessary when ordering a mask ROM production:

- 1.Mask ROM Confirmation Form
- 2.Mark Specification Form
- 3.Data to be written to ROM, in EPROM form (three identical copies) or in one floppy disk.

# CHAPTER 2

## **APPLICATION**

V <sub>REF</sub>	Open.
X <sub>OUT</sub>	Open (only when using external clock).
AV <sub>SS</sub>	Connect to V <sub>SS</sub> (GND).
V <sub>EE</sub>	Connect to V <sub>SS</sub> (GND).
CNV <sub>SS</sub>	Connect to V <sub>SS</sub> through a resistor of 1 kΩ to 10 kΩ.

### 2.1.4 Notes on I/O port

#### (1) Notes in standby state

In standby state\*<sup>1</sup> for low-power dissipation, do not make input levels of an input port and an I/O port “undefined”.

Pull-up (connect the port to VCC) or pull-down (connect the port to VSS) these ports through a resistor.

When determining a resistance value, note the following points:

- External circuit
- Variation of output levels during the ordinary operation

When using an optional built-in pull-up resistor, note on varied current values:

- When setting as an input port : Fix its input level
- When setting as an output port : Prevent current from flowing out to external

#### ● Reason

The potential which is input to the input buffer in a microcomputer is unstable in the state that input levels of a input port and an I/O port are “undefined”. This may cause power source current.

\*<sup>1</sup> standby state: stop mode by executing **STP** instruction  
wait mode by executing **WIT** instruction

#### (2) Modifying port latch of I/O port with bit managing instruction

When the port latch of an I/O port is modified with the bit managing instruction\*<sup>2</sup>, the value of the unspecified bit may be changed.

#### ● Reason

The bit managing instructions are read-modify-write form instructions for reading and writing data by a byte unit. Accordingly, when these instructions are executed on a bit of the port latch of an I/O port, the following is executed to all bits of the port latch.

- As for bit which is set for input port:  
The pin state is read in the CPU, and is written to this bit after bit managing.
- As for bit which is set for output port:  
The bit value is read in the CPU, and is written to this bit after bit managing.

Note the following:

- Even when a port which is set as an output port is changed for an input port, its port latch holds the output data.
- As for a bit of which is set for an input port, its value may be changed even when not specified with a bit managing instruction in case where the pin state differs from its port latch contents.

\*<sup>2</sup> Bit managing instructions: **SEB** and **CLB** instructions

#### (3) Pull-up/Pull-down control

When each port which has built-in pull-up/pull-down resistor is set to output port, pull-up/pull-down control of corresponding port becomes invalid. (Pull-up/pull-down cannot be set.)

#### ● Reason

Pull-up/pull-down control is valid only when each direction register is set to the input mode.

# APPLICATION

## 2.1 I/O port

---

### 2.1.5 Termination of unused pins

#### (1) Terminate unused pins

① Output ports : Open

② Input ports :

Connect each pin to VCC or VSS through each resistor of 1 kΩ to 10 kΩ.

As for pins whose potential affects to operation modes such as pin INT or others, select the VCC pin or the VSS pin according to their operation mode.

③ I/O ports :

- Set the I/O ports for the input mode and connect them to VCC or VSS through each resistor of 1 kΩ to 10 kΩ.

Ports that permit the selecting of a built-in pull-up resistor can also use this resistor. Set the I/O ports for the output mode and open them at “L” or “H”.

- When opening them in the output mode, the input mode of the initial status remains until the mode of the ports is switched over to the output mode by the program after reset. Thus, the potential at these pins is undefined and the power source current may increase in the input mode. With regard to an effects on the system, thoroughly perform system evaluation on the user side.
- Since the direction register setup may be changed because of a program runaway or noise, set direction registers by program periodically to increase the reliability of program.

#### (2) Termination remarks

① Input ports and I/O ports :

Do not open in the input mode.

● **Reason**

- The power source current may increase depending on the first-stage circuit.
- An effect due to noise may be easily produced as compared with proper termination ② and ③ shown on the above.

② I/O ports :

When setting for the input mode, do not connect to VCC or VSS directly.

● **Reason**

If the direction register setup changes for the output mode because of a program runaway or noise, a short circuit may occur between a port and VCC (or VSS).

③ I/O ports :

When setting for the input mode, do not connect multiple ports in a lump to VCC or VSS through a resistor.

● **Reason**

If the direction register setup changes for the output mode because of a program runaway or noise, a short circuit may occur between ports.

- At the termination of unused pins, perform wiring at the shortest possible distance (20 mm or less) from microcomputer pins.

## 2.2 Timer

### 2.2.3 Timer application examples

#### (1) Basic functions and uses

##### [Function 1] Control of event interval (Timer 1 to Timer 6, Timer X: timer mode)

When a certain time, by setting a count value to each timer, has passed, the timer interrupt request occurs.

<Use>

- Generating of an output signal timing
- Generating of a wait time

##### [Function 2] Control of cyclic operation (Timer 1 to Timer 6, Timer X: timer mode)

The value of the timer latch is automatically written to the corresponding timer each time the timer underflows, and each timer interrupt request occurs in cycles.

<Use>

- Generating of cyclic interrupts
- Clock function (measurement of 1 s); see "(2) Timer application example 1"
- Control of a main routine cycle

##### [Function 3] Output of rectangular waveform

(Timer 1, Timer 3, Timer 6, Timer X: pulse output mode)

The output level of the T<sub>1OUT</sub> pin, T<sub>3OUT</sub> pin, PWM<sub>1</sub> pin or CNTR<sub>2</sub> pin is inverted each time the timer underflows.

<Use>

- Piezoelectric buzzer output; see "(3) Timer application example 2"
- Generating of the remote control carrier waveforms

##### [Function 4] Count of external pulses (Timer 2, Timer 4, Timer X: event counter mode)

External pulses input to the CNTR<sub>0</sub> pin, CNTR<sub>1</sub> pin, CNTR<sub>2</sub> pin are counted as the timer count source (in the event counter mode).

<Use>

- Frequency measurement; see "(4) Timer application example 3"
- Division of external pulses
- Generating of interrupts due to a cycle using external pulses as the count source; count of a reel pulse

##### [Function 5] Output of PWM signal (Timer 6)

"H" interval and "L" interval are specified, respectively, and the output of pulses from P7<sub>4</sub>/PWM<sub>1</sub> pin is repeated.

<Use>

- Control of electric volume

##### [Function 6] Measurement of external pulse width (Timer X: pulse width measurement mode)

The "H" or "L" level width of external pulses input to CNTR<sub>2</sub> pin is measured.

<Use>

- Measurement of external pulse frequency (measurement of pulse width of FG pulse\* for a motor); see "(5) Timer application example 4"
  - Measurement of external pulse duty (when the frequency is fixed)
- FG pulse\*: Pulse used for detecting the motor speed to control the motor speed.

##### [Function 7] Control of real time port (Timer X: real time port function)

The data for real time is output from the P9<sub>4</sub> pin or P9<sub>5</sub> pin each time the timer underflows.

<Use>

- Stepping motor control; see "(6) Timer application example 5"

# APPLICATION

## 2.2 Timer

### (2) Timer application example 1: Clock function (measurement of 1 s)

**Outline:** The input clock is divided by the timer so that the clock can count up at 1 s intervals.

**Specifications:** •The clock  $f(X_{IN}) = 4.19 \text{ MHz}$  ( $2^{22} \text{ Hz}$ ) is divided by the timer.

- The timer 3 interrupt request bit is checked in main routine, and if the interrupt request is issued, the clock is counted up.
- The timer 1 interrupt occurs every  $244 \mu\text{s}$  to execute processing of other interrupts.

Figure 2.2.15 shows the timers connection and setting of division ratios; Figure 2.2.16 shows the relevant registers setting; Figure 2.2.17 shows the control procedure.

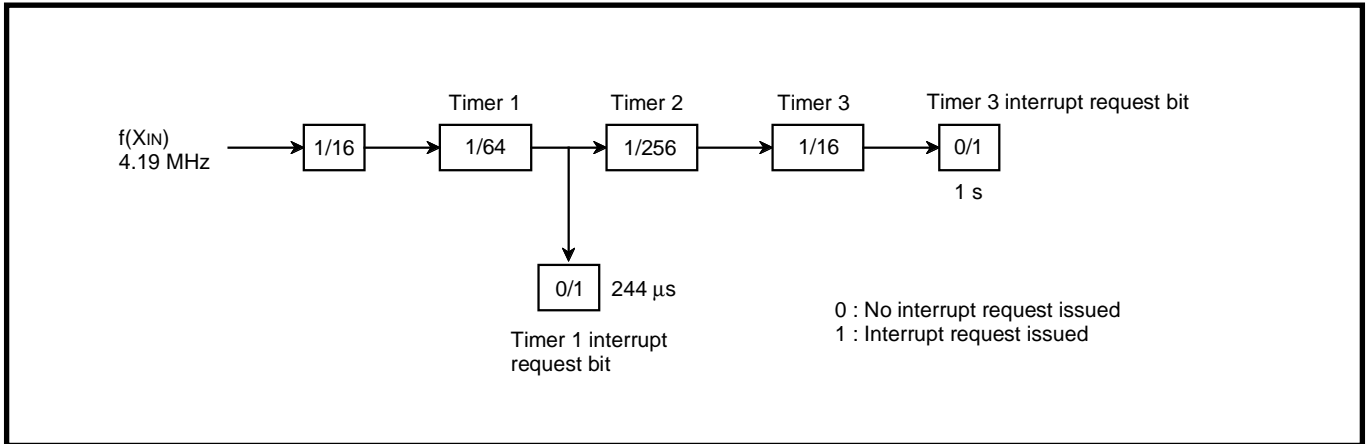

Fig. 2.2.15 Timers connection and setting of division ratios

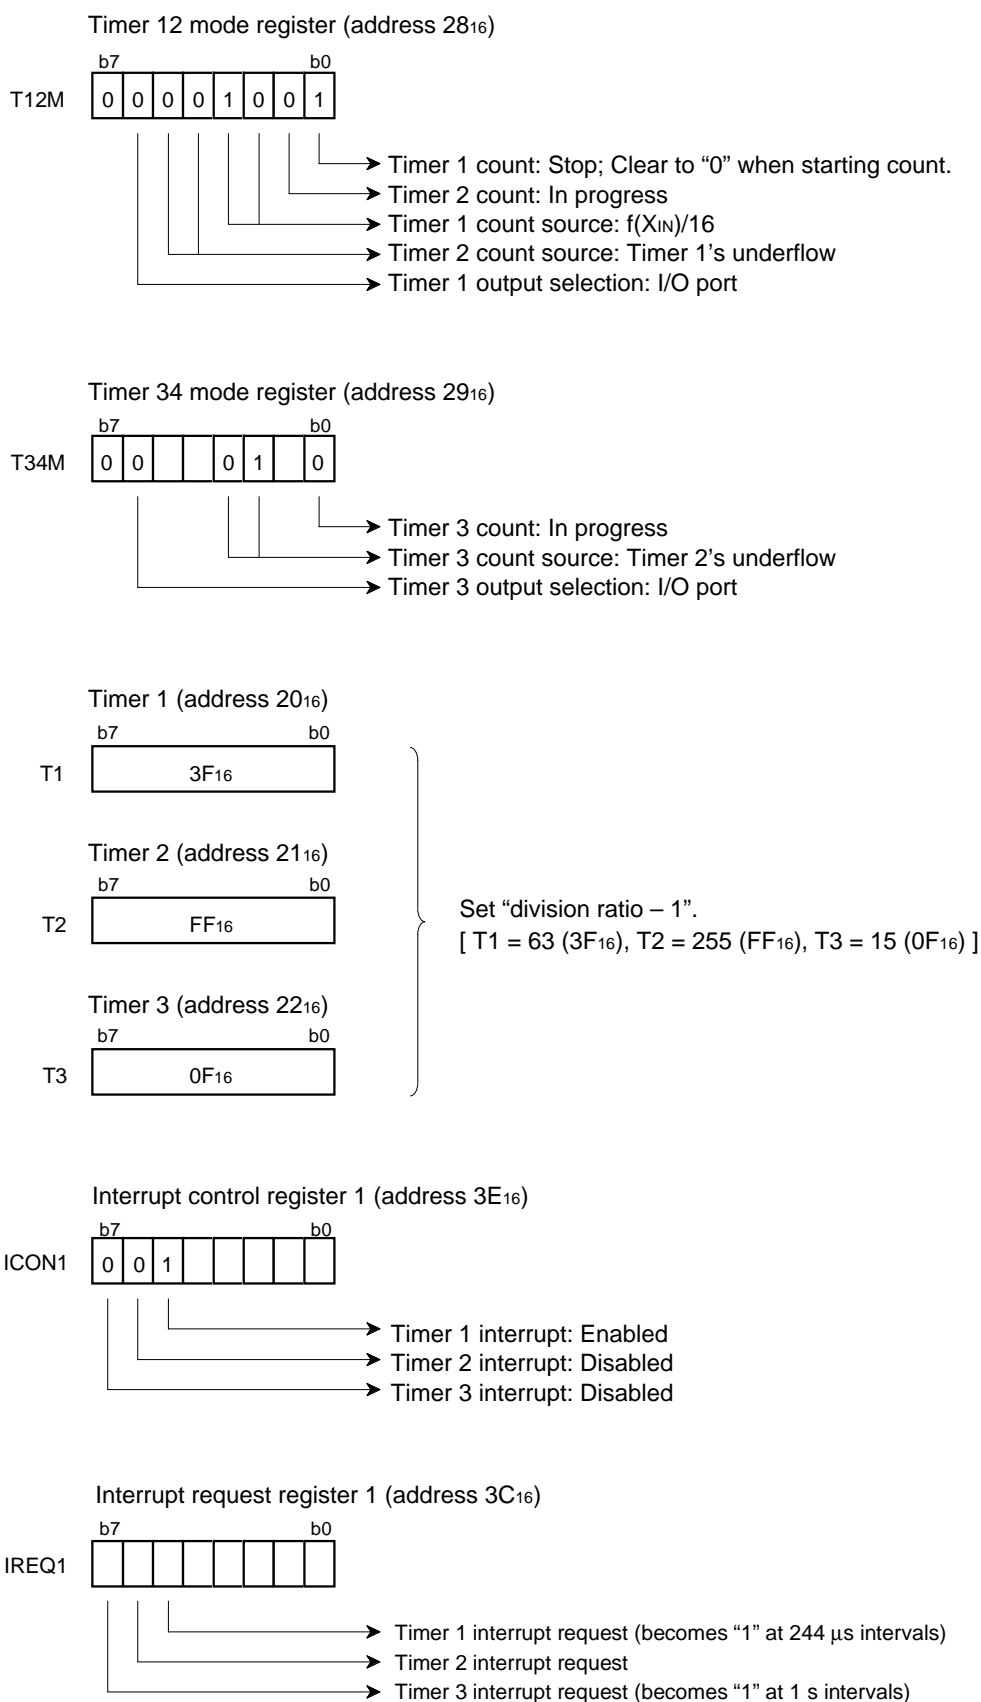

Fig. 2.2.16 Relevant registers setting

# APPLICATION

## 2.2 Timer

Fig. 2.2.17 Control procedure

### (3) Timer application example 2: Piezoelectric buzzer output

**Outline:** The rectangular waveform output function of the timer is applied for a piezoelectric buzzer output.

- Specifications:**
- The rectangular waveform, dividing the clock  $f(X_{IN}) = 4.19 \text{ MHz}$  ( $2^{22} \text{ Hz}$ ) into about 2 kHz (2048 Hz), is output from the P7<sub>6</sub>/T<sub>3OUT</sub> pin.
  - The level of the P7<sub>6</sub>/T<sub>3OUT</sub> pin is fixed to “H” while a piezoelectric buzzer output stops.

Figure 2.2.18 shows a peripheral circuit example, and Figure 2.2.19 shows the timers connection and setting of division ratios. Figure 2.2.20 shows the relevant registers setting, and Figure 2.2.21 shows the control procedure.

# APPLICATION

## 2.2 Timer

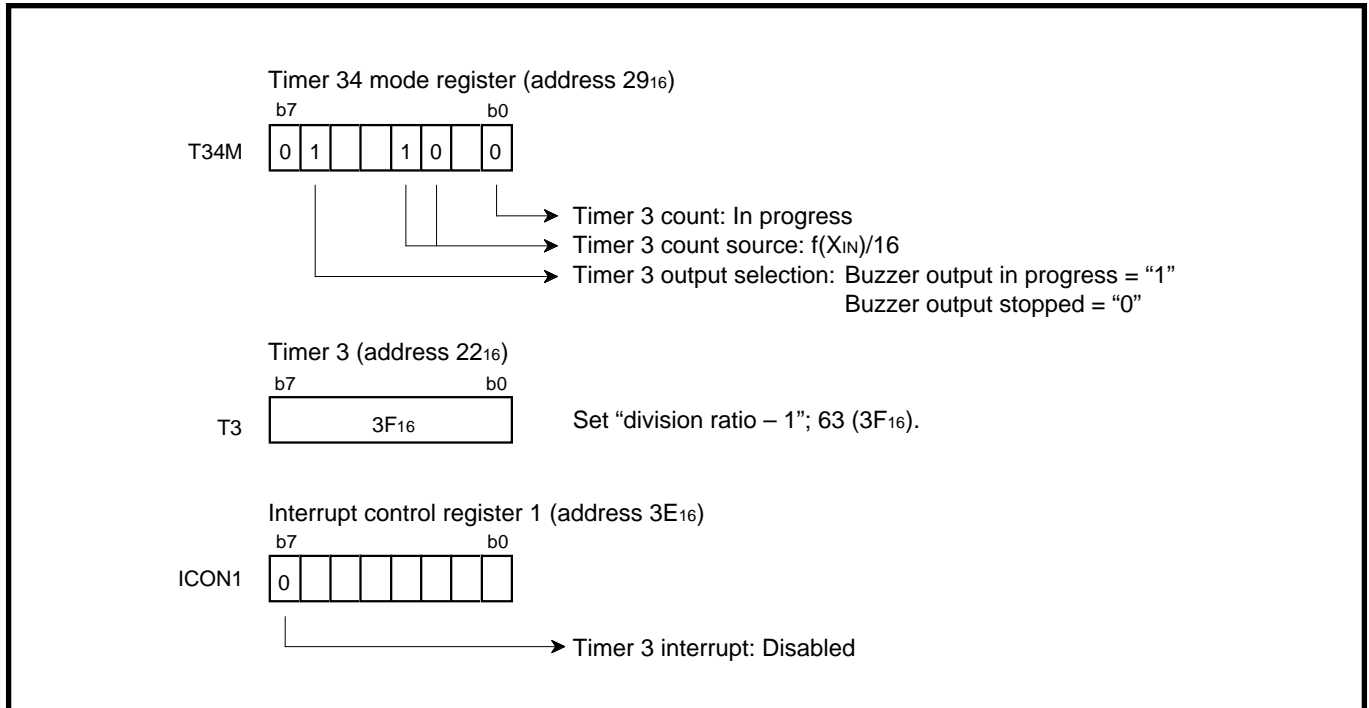

Fig. 2.2.20 Relevant registers setting

Fig. 2.2.21 Control procedure

**(4) Timer application example 3: Frequency measurement**

**Outline:** The following two values are compared to judge whether the frequency is within a valid range.

- A value by counting pulses input to P8<sub>2</sub>/CNTR<sub>1</sub> pin with the timer.
- A reference value

**Specifications:**

- The pulse is input to the P8<sub>2</sub>/CNTR<sub>1</sub> pin and counted by the timer 4. (**Note 1**)
- A count value of timer 4 is read out at about 2 ms intervals, the timer 1 interrupt interval. When the count value is 28 to 40, it is judged that the input pulse is valid.
- Because the timer is a down-counter, the count value is compared with 227 to 215 (**Note 2**).

**Notes 1:** In the mask option type P, use the CNTR<sub>0</sub> pin and timer 2.

**2:** 227 to 215 = {255 (initial value of counter) – 28} to {255 – 40}; 28 to 40 means the number of valid value.

Figure 2.2.22 shows the judgment method of valid/invalid of input pulses; Figure 2.2.23 shows the relevant registers setting; Figure 2.2.24 shows the control procedure.

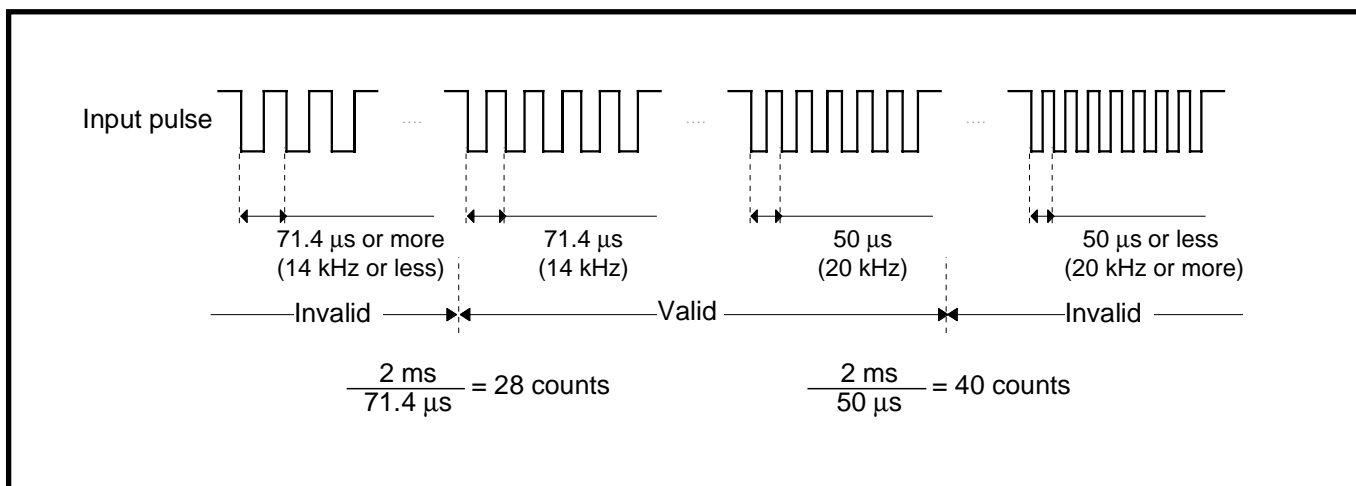

Fig. 2.2.22 Judgment method of valid/invalid of input pulses

# APPLICATION

## 2.2 Timer

### (5) Timer application example 4: Measurement of FG pulse width for motor

**Outline:** The timer X counts the “H” level width of the pulses input to the P8<sub>3</sub>/CNTR<sub>0</sub>/CNTR<sub>2</sub> pin. An underflow is detected by the timer X interrupt and an end of the input pulse “H” level is detected by the timer 2 interrupt of which count source is the input to P8<sub>3</sub>/CNTR<sub>0</sub>/CNTR<sub>2</sub> pin.

**Specifications:** •The timer X counts the “H” level width of the FG pulse input to the P8<sub>3</sub>/CNTR<sub>0</sub>/CNTR<sub>2</sub> pin.

<Example>

When  $f(X_{IN}) = 4.19 \text{ MHz}$ , the count source is  $15.2 \mu\text{s}$ , which is obtained by dividing the clock frequency by 64. Measurement can be made up to 1 s in the range of  $\text{FFFF}_{16}$  to  $\text{0000}_{16}$ .

Figure 2.2.25 shows the timers connection and setting of division ratio; Figure 2.2.26 shows the relevant registers setting; Figure 2.2.27 shows the control procedure.

# APPLICATION

## 2.2 Timer

● X: This bit is not used here. Set it to "0" or "1" arbitrary.

- All interrupts disabled
- Setting P83/CNTR0/CNTR2 pin to input mode
- Timer X: Pulse width measurement mode (Measuring "H" pulse width of input pulses from CNTR2 pin)
- Setting Timer X count value
- CNTR0 pin edge: Falling edge count
- External pulses input from CNTR0 pin selected as Timer 2's count source
- Setting "0" to Timer 2
- Timers X and 2 interrupts: Enabled
- Timers X and 2 count start
- Interrupts enabled

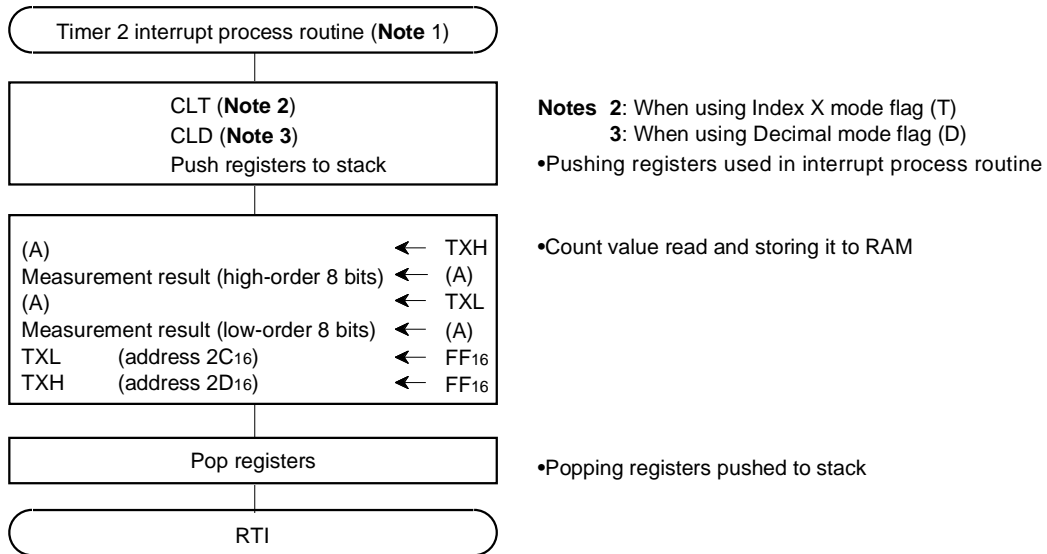

**Notes 1:** Timer X interrupt also occurs owing to factors other than measurement level.(CNTR2 input = "L" in this application) Process it by software as error processing is performed for measurement level as necessary . CNTR2 input level can be checked by reading the contents of sharing port P83 register.

- 2:** When using Index X mode flag (T)
- 3:** When using Decimal mode flag (D)

•Pushing registers used in interrupt process routine

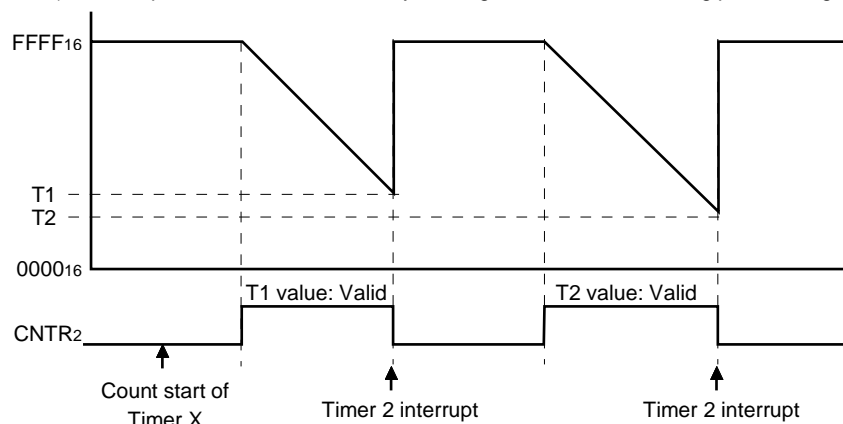

•Popping registers pushed to stack

**Fig. 2.2.27 Control procedure**

**Note 1:** The first value becomes invalid depending on start timing of Time X count shown by the following figure.  
Process it by software as necessary.

[ **Example 1** ] • Start Timer X count when CNTR2 input level is "L".  
(CNTR2 input level can be checked by reading the contents of sharing port P83 register.)

[ **Example 2** ] • Start Timer X count when CNTR2 input level is "H".  
Invalidate the first Timer 2 interrupt after start of Timer X count.

# APPLICATION

## 2.2 Timer

### (6) Timer application example 5: Control of stepping motor

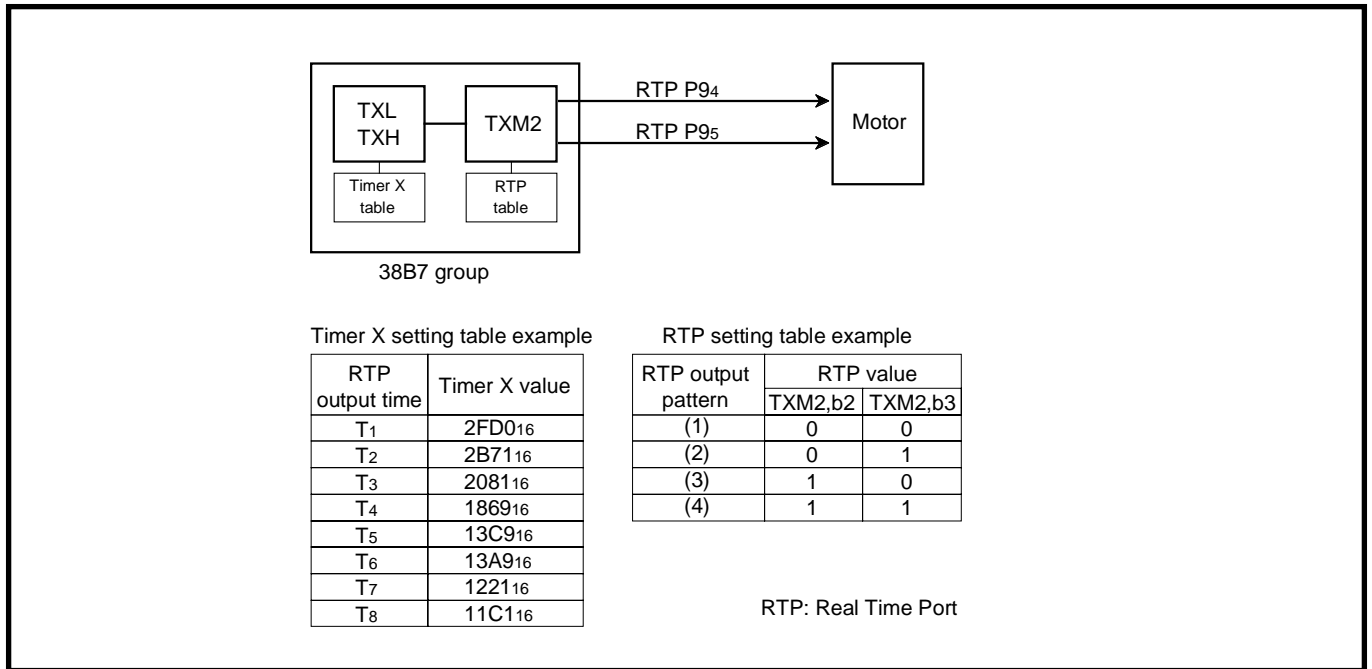

**Outline:** The rotating of stepping motor is controlled by using real time output ports.

**Specifications:** •The motor is controlled by using 2 real time output ports.

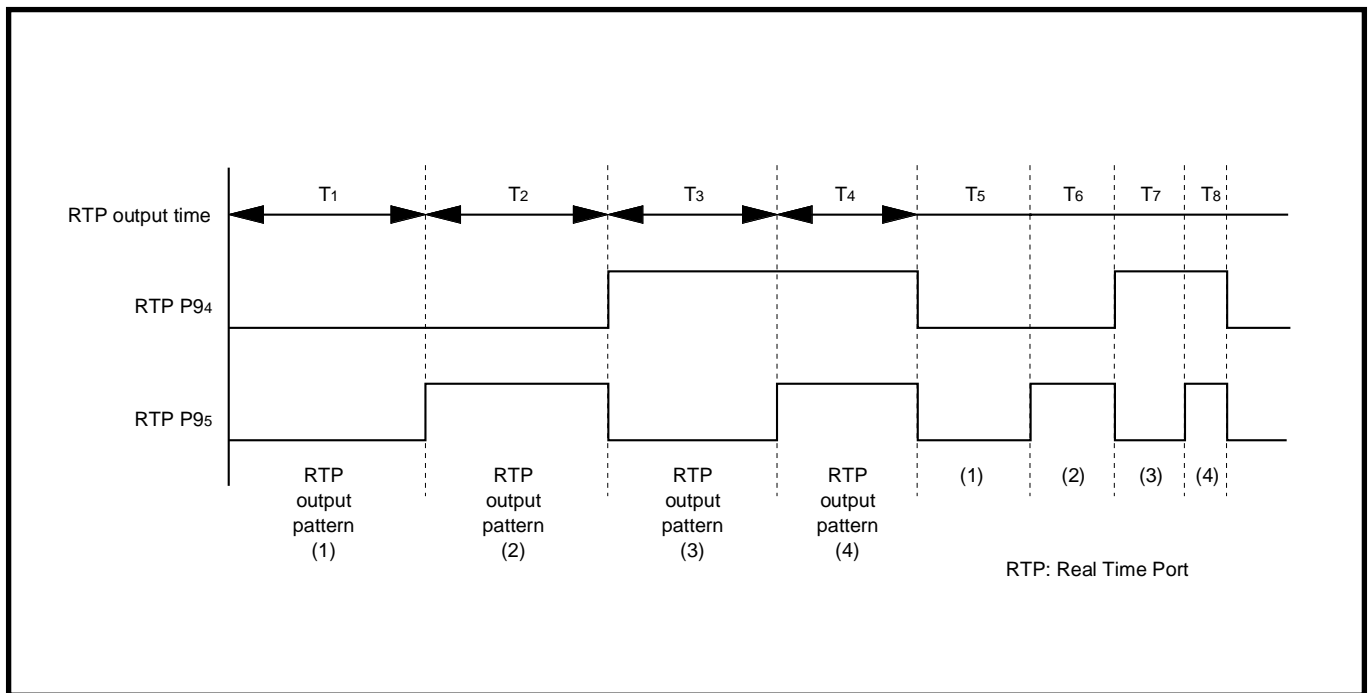

•The count source is  $f(X_{IN}) = 4.19 \text{ MHz}$  divided by 8.

•Values of Timer X and real time output are updated in the timer X interrupt routine

Figure 2.2.28 shows the timers connection and the table example of timer X/RTP setting values; Figure 2.2.29 shows the RTP output example; Figure 2.2.30 shows the relevant registers setting; Figure 2.2.31 shows the control procedure.

### 2.3.5 Serial I/O1 application examples

#### (1) Output of serial data (control of peripheral IC)

**Outline :** Serial communication is performed, connecting ports with the  $\overline{CS}$  pin of a peripheral IC.

Figure 2.3.22 shows a connection diagram, and Figure 2.3.23 shows a timing chart.

Fig. 2.3.22 Connection diagram

**Specifications :**

- Use of serial I/O1 (Not using automatic transfer function)

- Synchronous clock frequency : 131 kHz ( $f(X_{IN}) = 4.19 \text{ MHz}$  is divided by 32)
- Transfer direction : LSB first
- Not use of serial I/O1 interrupt
- Port PB<sub>1</sub> is connected to the  $\overline{CS}$  pin ("L" active) of the peripheral IC for transmission control; the output level of port PB<sub>1</sub> is controlled by software.

Fig. 2.3.23 Timing chart

# APPLICATION

## 2.3 Serial I/O

Figure 2.3.24 shows the registers setting relevant to the transmission side, and Figure 2.3.25 shows the setting of transmission data.

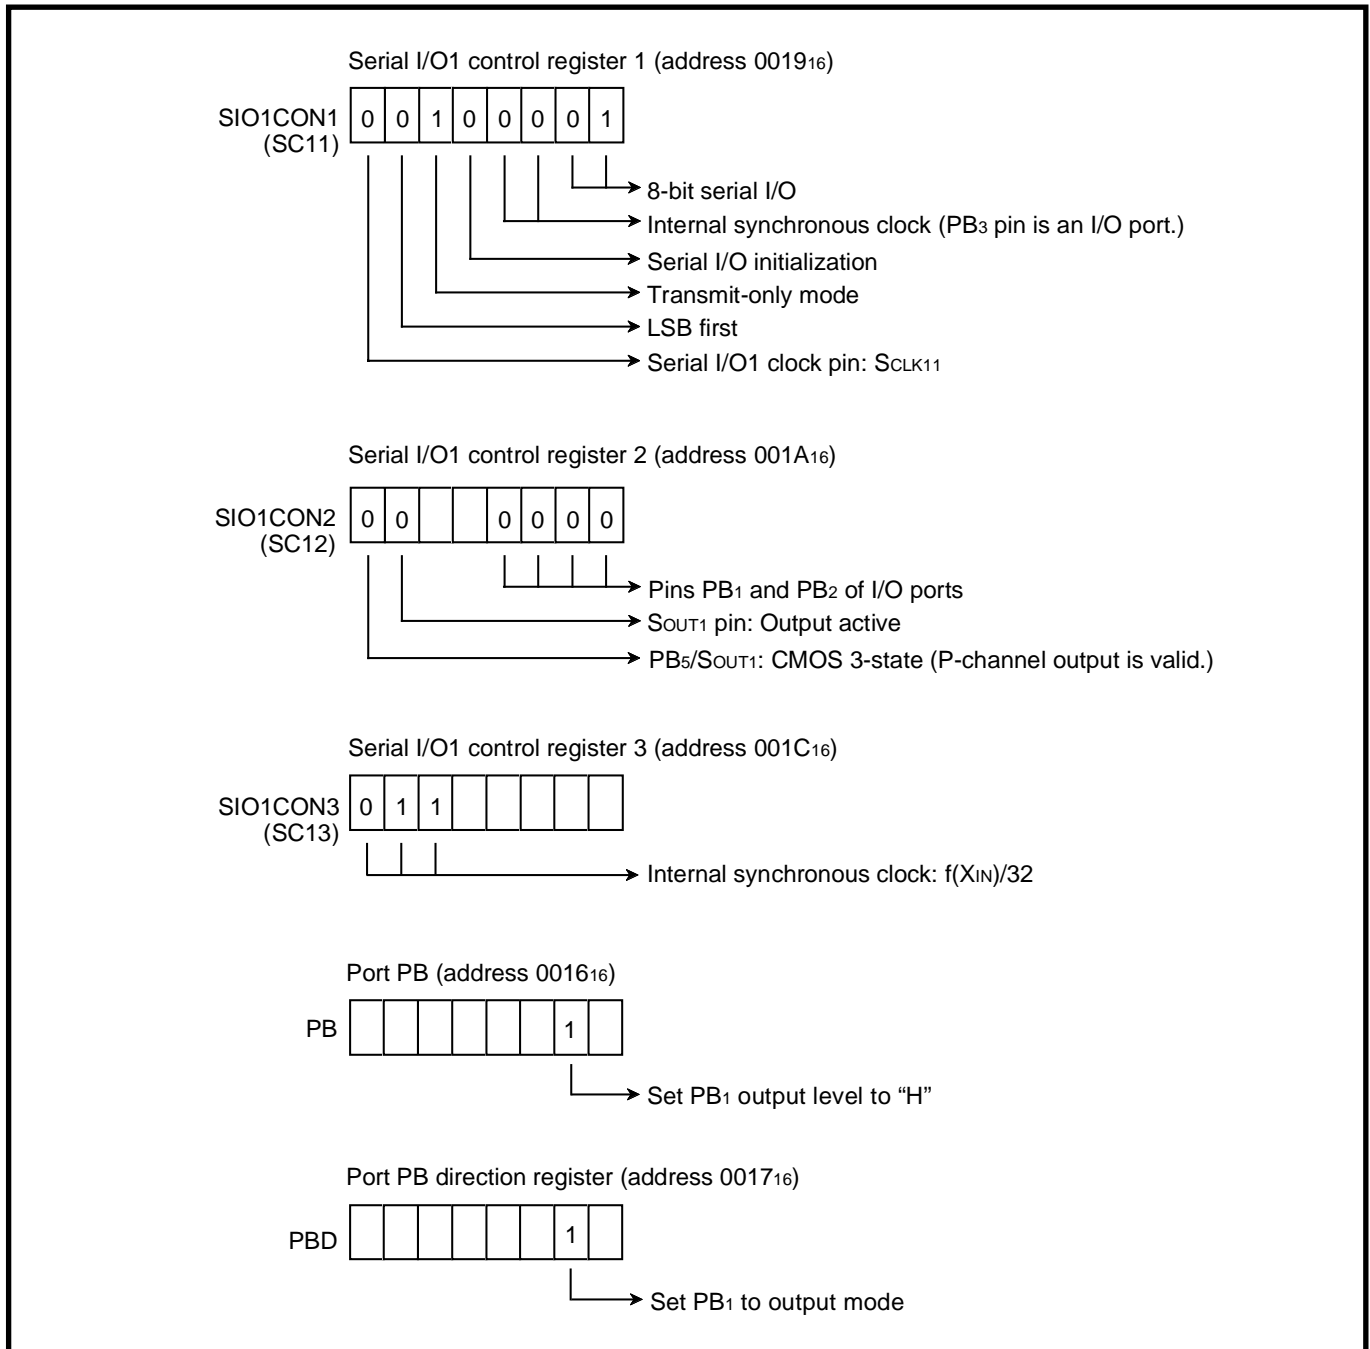

Fig. 2.3.24 Registers setting relevant to transmission side

Fig. 2.3.25 Setting of transmission data

**Control procedure:** When the registers are set as shown in Figure 2.3.24, the serial I/O1 can transmit 1-byte data by writing data to the serial I/O1 register.

Thus, after setting the  $\overline{CS}$  signal to "L", write the transmission data to the serial I/O1 register by each 1 byte; and return the  $\overline{CS}$  signal to "H" when the target number of bytes has been transmitted.

Figure 2.3.26 shows a control procedure.

## 2.3 Serial I/O

### (2) Transmission/Reception using automatic transfer

**Outline:** Serial transmission/reception control is performed, using the serial automatic transfer function.

Figure 2.3.27 shows a connection diagram, and Figure 2.3.28 shows a timing chart of serial data transmission/reception.

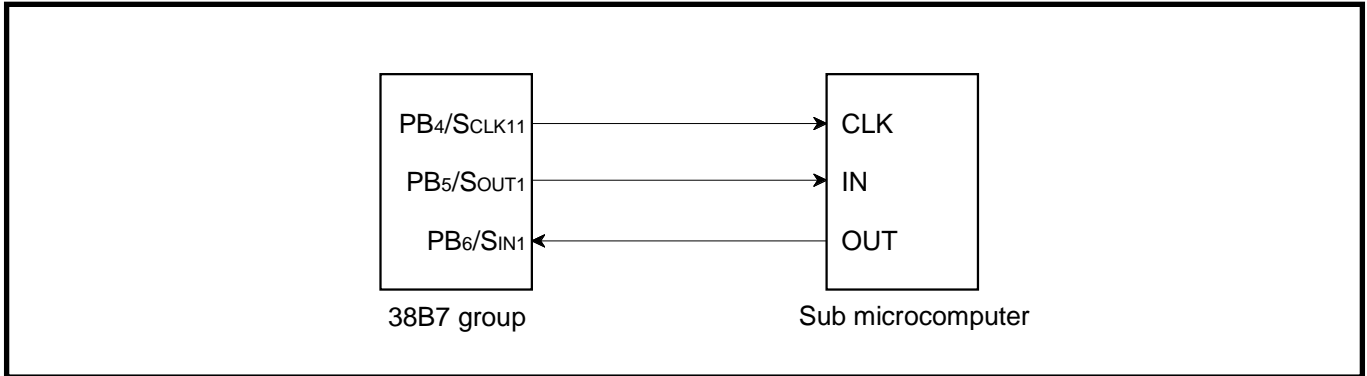

Fig. 2.3.27 Connection diagram

- Specifications:**
- Use of serial I/O1 using automatic transfer function
  - Synchronous clock frequency: 131 kHz ( $f(X_{IN}) = 4.19 \text{ MHz}$  is divided by 32.)
  - Transfer direction: LSB first
  - Transmission/reception byte number: 8 bytes/block each
  - Transfer interval for 1-byte:  $244 \mu\text{s}$  (32 cycles of transfer clock)
  - Not use of serial I/O1 automatic transfer interrupt

Figure 2.3.29 shows the relevant registers setting, and Figure 2.3.30 shows the control procedure.

# APPLICATION

## 2.3 Serial I/O

### 2.3.8 Serial I/O2 application examples

#### (1) Communication (transmission/reception) using clock synchronous serial I/O

**Outline :** 2-byte data is transmitted and received, using the clock synchronous serial I/O.  
The  $\overline{\text{SRDY2}}$  signal is used for communication control.

Figure 2.3.35 shows a connection diagram, and Figure 2.3.36 shows a timing chart.

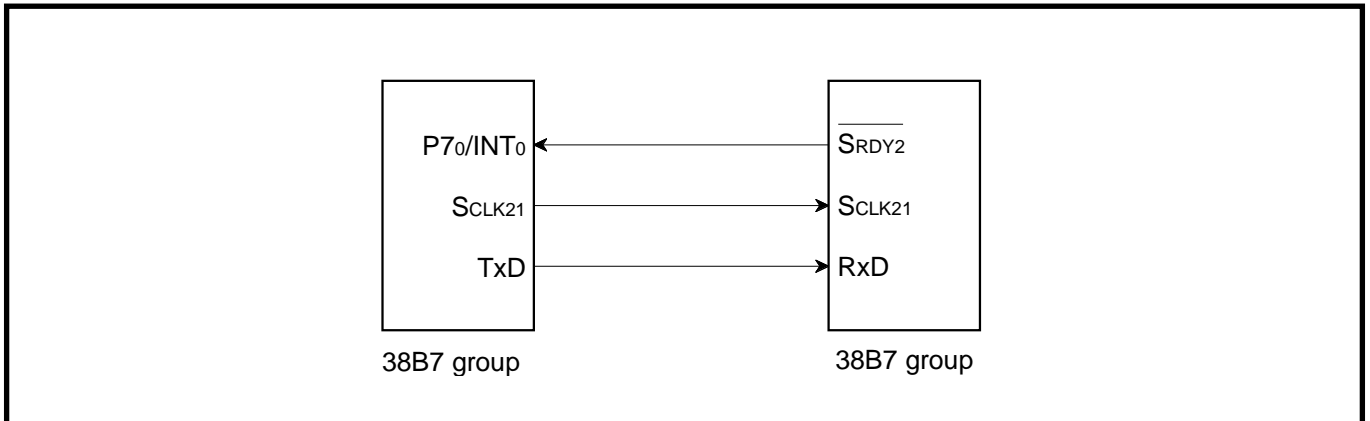

Fig. 2.3.35 Connection diagram

#### Specifications :

- Use of serial I/O2 in clock synchronous serial I/O

- Synchronous clock frequency : 125 kHz ( $f(X_{IN}) = 4 \text{ MHz}$  is divided by 32)
- Use of  $\overline{\text{SRDY2}}$  (receivable signal)
- The reception side outputs the  $\overline{\text{SRDY2}}$  signal at intervals of 2 ms (generated by the timer), and 2-byte data is transferred from the transmission side to the reception side.

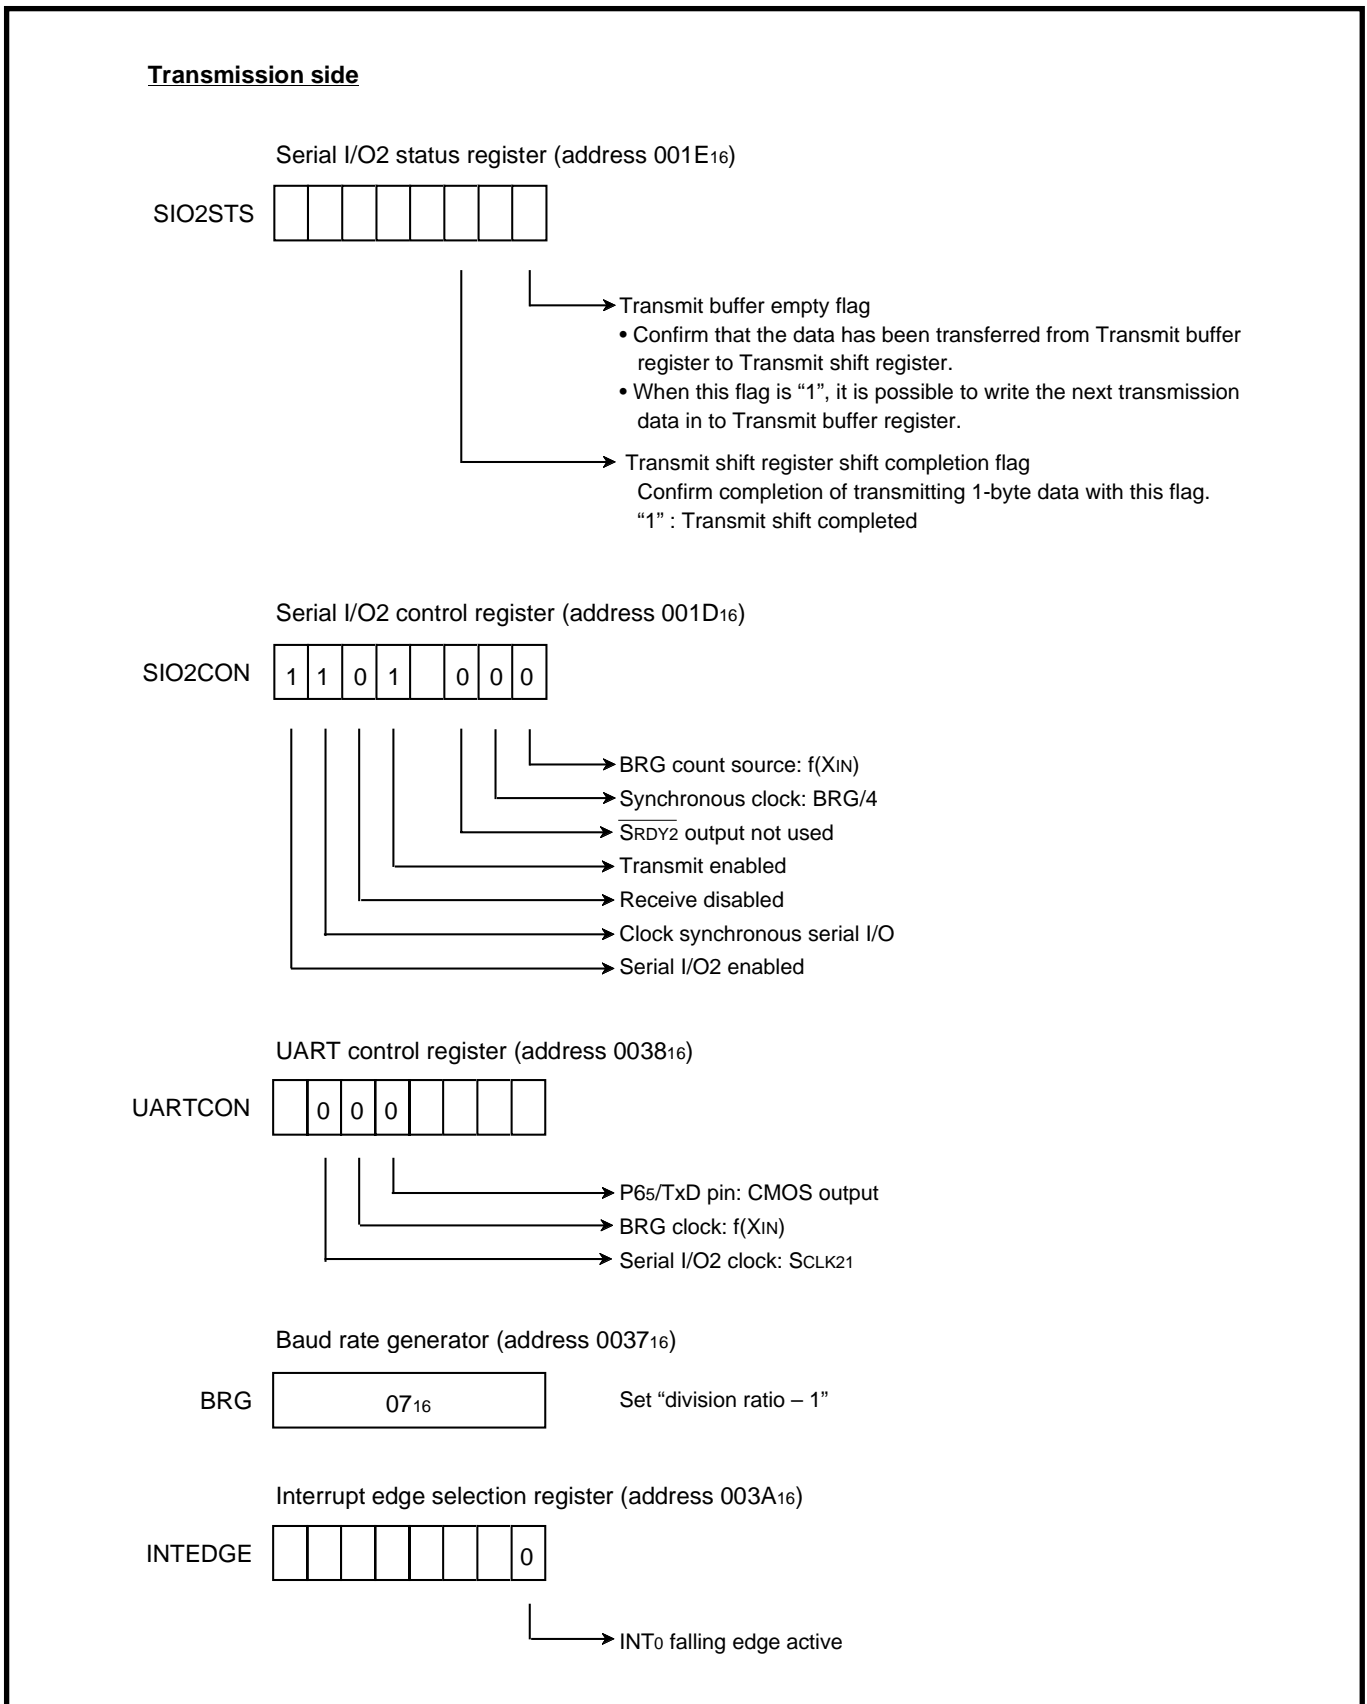

Fig. 2.3.36 Timing chart

Figure 2.3.45 shows a control procedure.

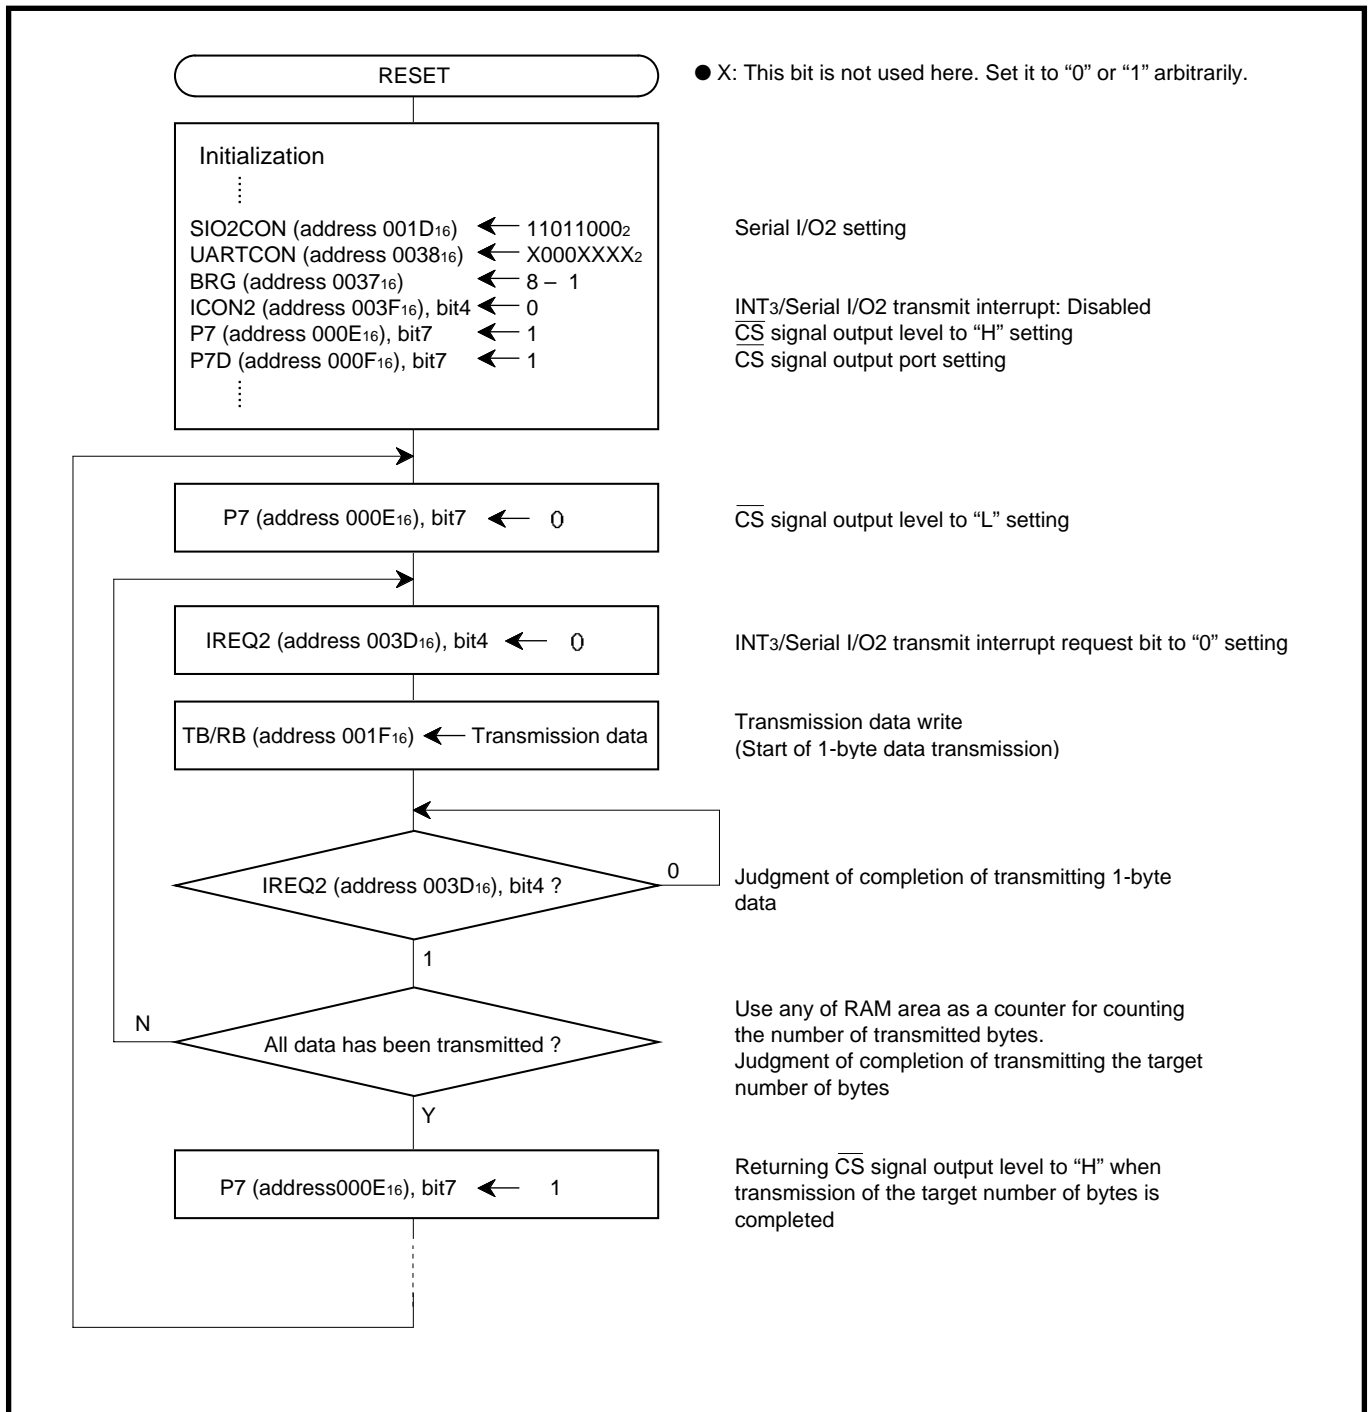

Fig. 2.3.45 Control procedure

# APPLICATION

## 2.3 Serial I/O

### (3) Cyclic transmission or reception of block data (data of specified number of bytes) between two microcomputers

**Outline :** When the clock synchronous serial I/O is used for communication, synchronization of the clock and the data between the transmitting and receiving sides may be lost because of noise included in the synchronous clock. It is necessary to correct that constantly, using "heading adjustment".

This "heading adjustment" is carried out by using the interval between blocks in this example.

Figure 2.3.46 shows a connection diagram.

Fig. 2.3.46 Connection diagram

- Specifications:**
- Use of serial I/O2 in clock synchronous serial I/O
  - Synchronous clock frequency : 131 kHz ( $f(X_{IN}) = 4.19 \text{ MHz}$  is divided by 32.)
  - Byte cycle: 488  $\mu\text{s}$
  - Number of bytes for transmission or reception : 8 bytes/block each
  - Block transfer cycle : 16 ms
  - Block transfer term : 3.5 ms
  - Interval between blocks : 12.5 ms
  - Heading adjustment time : 8 ms
  - Transfer direction : LSB first

**Limitations of the specifications:**

- Reading of the reception data and setting of the next transmission data must be completed within the time obtained from "byte cycle – time for transferring 1-byte data" (in this example, the time taken from generating of the serial I/O2 receive interrupt request to input of the next synchronous clock is 431  $\mu\text{s}$ ).
- "Heading adjustment time < interval between blocks" must be satisfied.

The communication is performed according to the timing shown in Figure 2.3.47. In the slave unit, when a synchronous clock is not input within a certain time (heading adjustment time), the next clock input is processed as the beginning (heading) of a block.

When a clock is input again after one block (8 bytes) is received, the clock is ignored.

Figure 2.3.48 shows the relevant registers setting in the master unit and Figure 2.3.49 shows the relevant registers setting in the slave unit.

Fig. 2.3.47 Timing chart

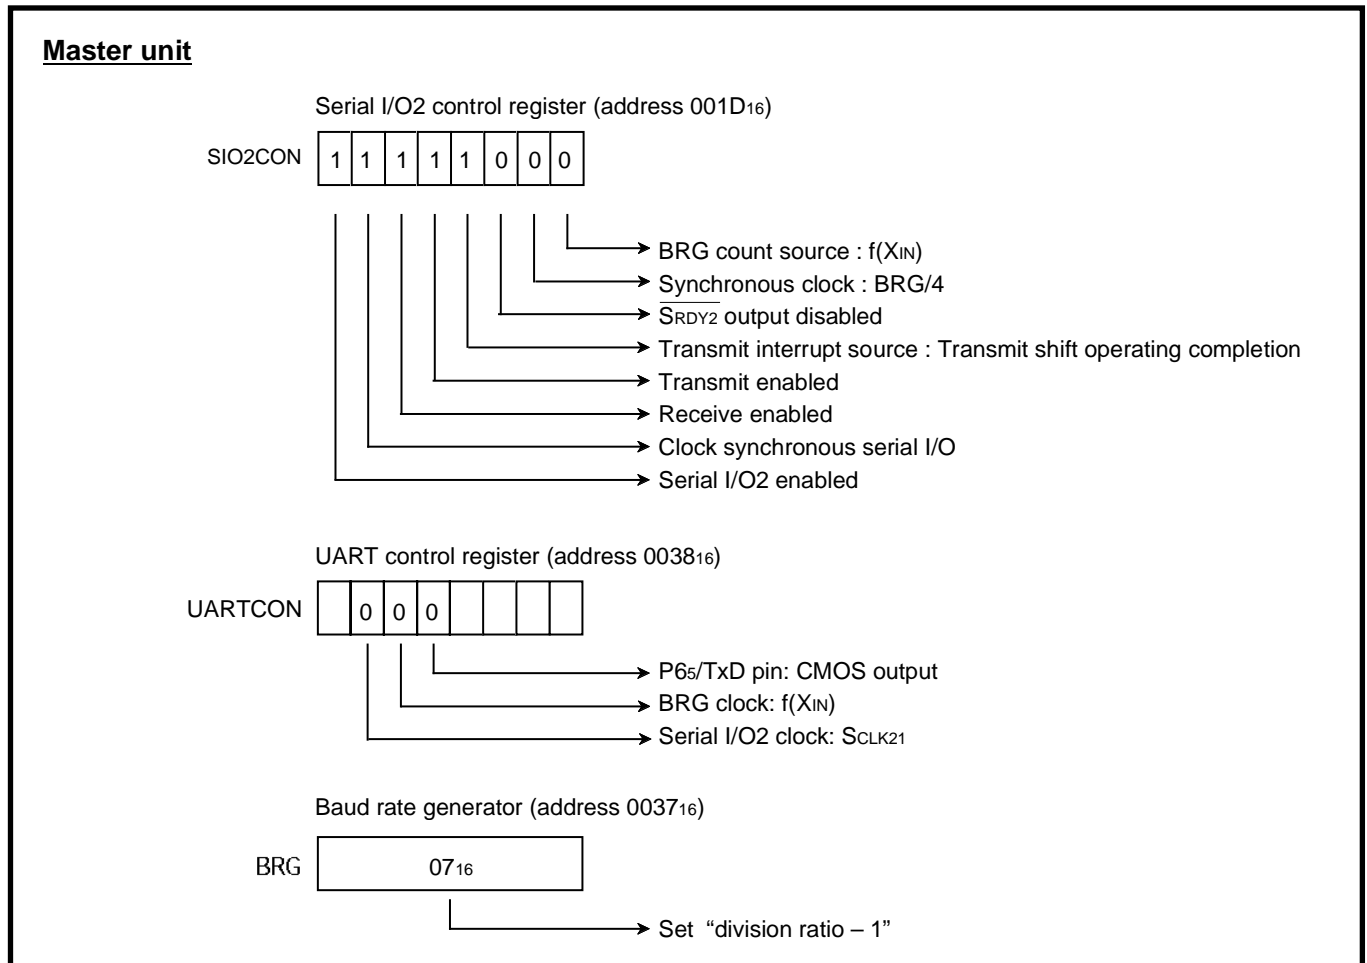

Fig. 2.3.48 Relevant registers setting in master unit

# APPLICATION

## 2.3 Serial I/O

Fig. 2.3.49 Relevant registers setting in slave unit

### Control procedure by software:

- Control in the master unit

After setting the relevant registers shown in Figure 2.3.48, the master unit starts transmission or reception of 1-byte data by writing transmission data to the serial I/O2 transmit buffer register. To perform the communication in the timing shown in Figure 2.3.47, take the timing into account and write transmission data. Additionally, read out the reception data when the serial I/O2 transmit interrupt request bit is set to "1," or before the next transmission data is written to the serial I/O2 transmit buffer register.

Figure 2.3.50 shows a control procedure of the master unit using timer interrupts.

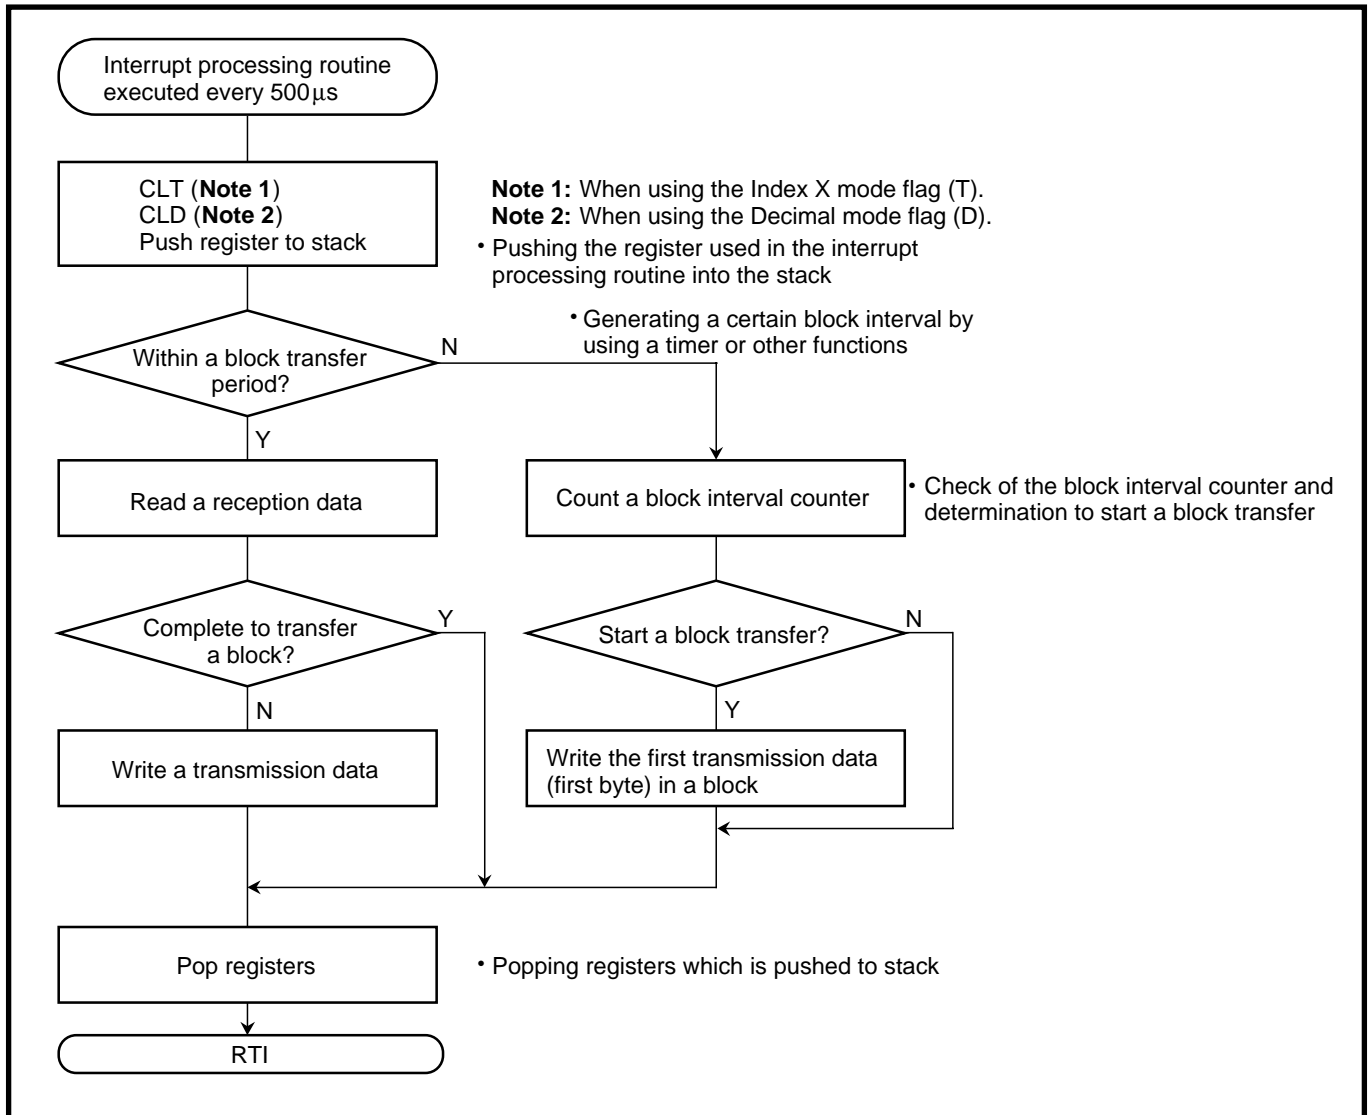

Fig. 2.3.50 Control procedure of master unit

# APPLICATION

## 2.3 Serial I/O

### ● Control in the slave unit

After setting the relevant registers as shown in Figure 2.3.49, the slave unit becomes the state where a synchronous clock can be received at any time, and the serial I/O2 receive interrupt request bit is set to “1” each time an 8-bit synchronous clock is received.

In the serial I/O2 receive interrupt processing routine, the data to be transmitted next is written to the transmit buffer register after the received data is read out.

However, if no serial I/O2 receive interrupt occurs for a certain time (heading adjustment time or more), the following processing will be performed.

1. The first 1-byte data of the transmission data in the block is written into the transmit buffer register.
2. The data to be received next is processed as the first 1 byte of the received data in the block.

Figure 2.3.51 shows a control procedure of the slave unit using the serial I/O2 receive interrupt and any timer interrupt (for heading adjustment).

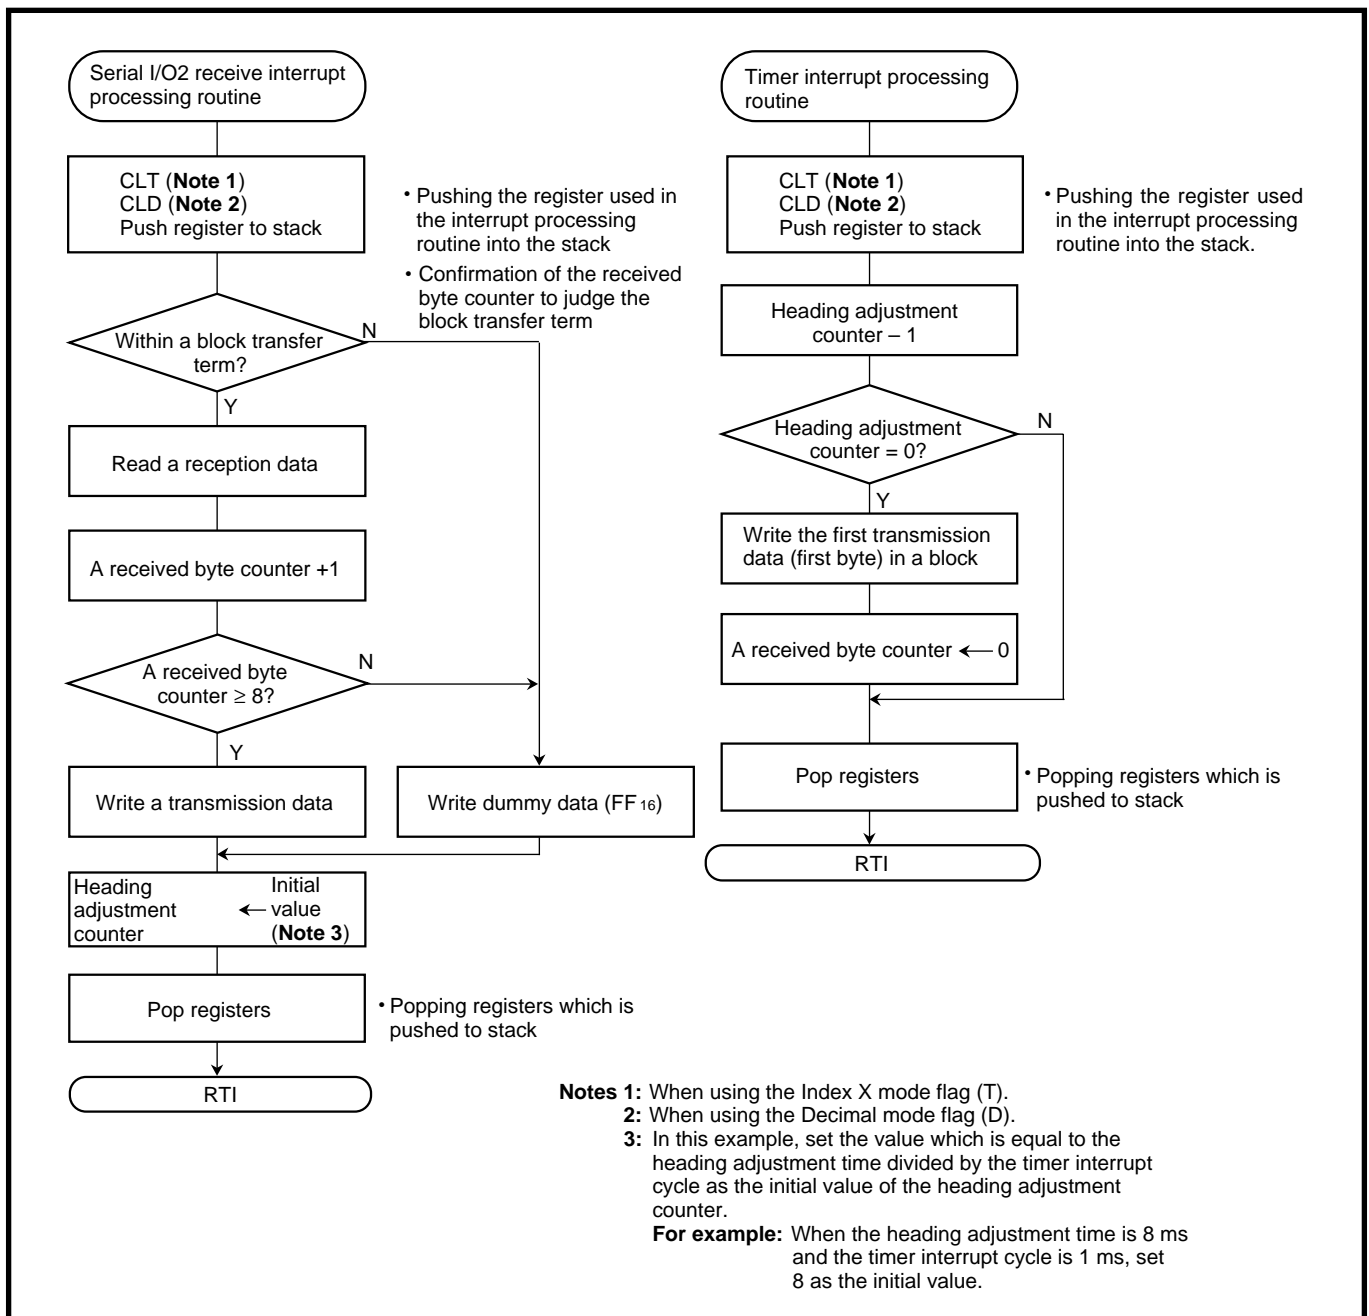

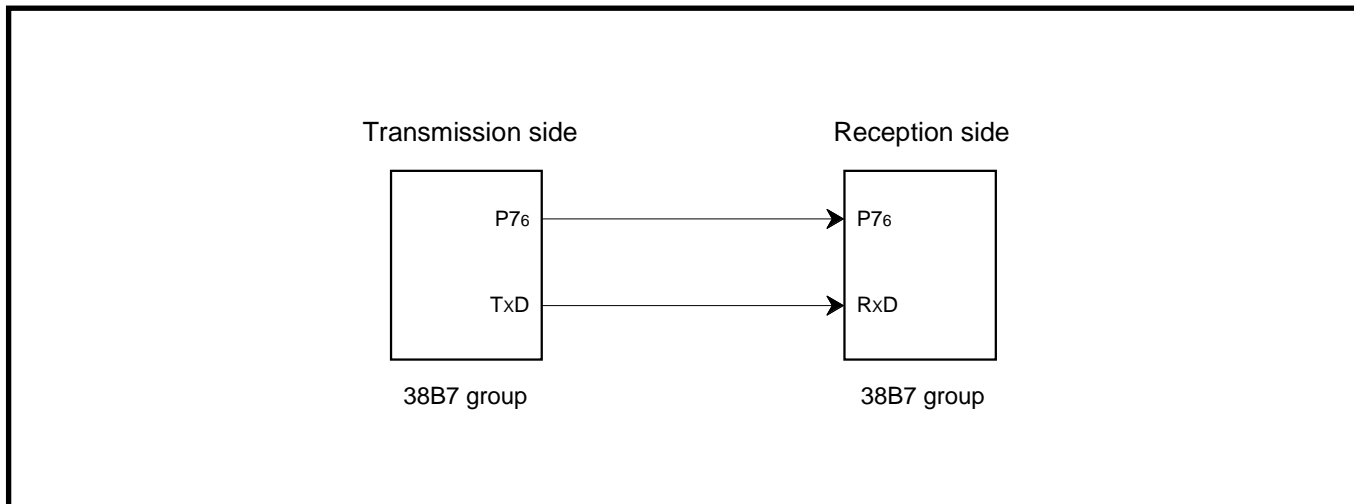

Fig. 2.3.51 Control procedure of slave unit

### (4) Communication (transmission/reception) using asynchronous serial I/O (UART)

**Outline :** 2-byte data is transmitted and received, using the asynchronous serial I/O.  
Port P7<sub>6</sub> is used for communication control.

Figure 2.3.52 shows a connection diagram, and Figure 2.3.53 shows a timing chart.

**Fig. 2.3.52 Connection diagram**

**Specifications :**

- Use of serial I/O<sub>2</sub> in UART

- Transfer bit rate : 9600 bps ( $f(X_{IN}) = 3.6864 \text{ MHz}$  is divided by 384)
- Data format : 1ST-8DADA-2ST
- Communication control using port P7<sub>6</sub>  
(The output level of port P7<sub>6</sub> is controlled by software.)
- 2-byte data is transferred from the transmission side to the reception side at intervals of 10 ms generated by the timer.

**Fig. 2.3.53 Timing chart**

# APPLICATION

## 2.3 Serial I/O

Table 2.3.1 shows setting examples of the baud rate generator (BRG) values and transfer bit rate values.

**Table 2.3.1 Setting examples of baud rate generator values and transfer bit rate values**

Transfer bit rate (Note 1)	f(XIN) = 3.6864 MHz			f(XIN) = 4 MHz		
	BRG count source (Note 2)	BRG setting value	Actual rate	BRG count source (Note 2)	BRG setting value	Actual rate
600	f(XIN)/4	95(5F <sub>16</sub> )	600.00	f(XIN)/4	103(67 <sub>16</sub> )	600.96
1200	f(XIN)/4	47(2F <sub>16</sub> )	1200.00	f(XIN)/4	51(33 <sub>16</sub> )	1201.92
2400	f(XIN)/4	23(17 <sub>16</sub> )	2400.00	f(XIN)/4	25(19 <sub>16</sub> )	2403.85
4800	f(XIN)/4	11(0B <sub>16</sub> )	4800.00	f(XIN)/4	12(0C <sub>16</sub> )	4807.69
9600	f(XIN)/4	5(05 <sub>16</sub> )	9600.00	f(XIN)	25(19 <sub>16</sub> )	9615.38
19200	f(XIN)/4	2(02 <sub>16</sub> )	19200.00	f(XIN)	12(0C <sub>16</sub> )	19230.77
38400	f(XIN)	5(05 <sub>16</sub> )	38400.00	f(XIN)	5(05 <sub>16</sub> )	41666.67
76800	f(XIN)	2(02 <sub>16</sub> )	76800.00	f(XIN)	2(02 <sub>16</sub> )	83333.33
31250	—	—	—	f(XIN)	7(07 <sub>16</sub> )	31250.00
62500	—	—	—	f(XIN)	3(03 <sub>16</sub> )	62500.00

**Notes 1:** Equation of transfer bit rate:

$$\text{Transfer bit rate (bps)} = \frac{f(\text{XIN})}{(\text{BRG setting value} + 1) \times 16 \times m^*}$$

\*m: When bit 0 of the serial I/O2 control register (address 001D<sub>16</sub>) is set to “0”, a value of m is 1.

When bit 0 of the serial I/O2 control register is set to “1”, a value of m is 4.

**2:** Select the BRG count source with bit 0 of the serial I/O2 control register (address 001D<sub>16</sub>).

# APPLICATION

## 2.3 Serial I/O

**Control procedure:** When the registers are set as shown in Figure 2.3.65, the serial I/O3 can transmit 1-byte data by writing data to the serial I/O3 register. Thus, after setting the  $\overline{CS}$  signal to "L", write the transmission data to the serial I/O3 register by each 1 byte; and return the  $\overline{CS}$  signal to "H" when the target number of bytes has been transmitted. Figure 2.3.65 shows a control procedure.

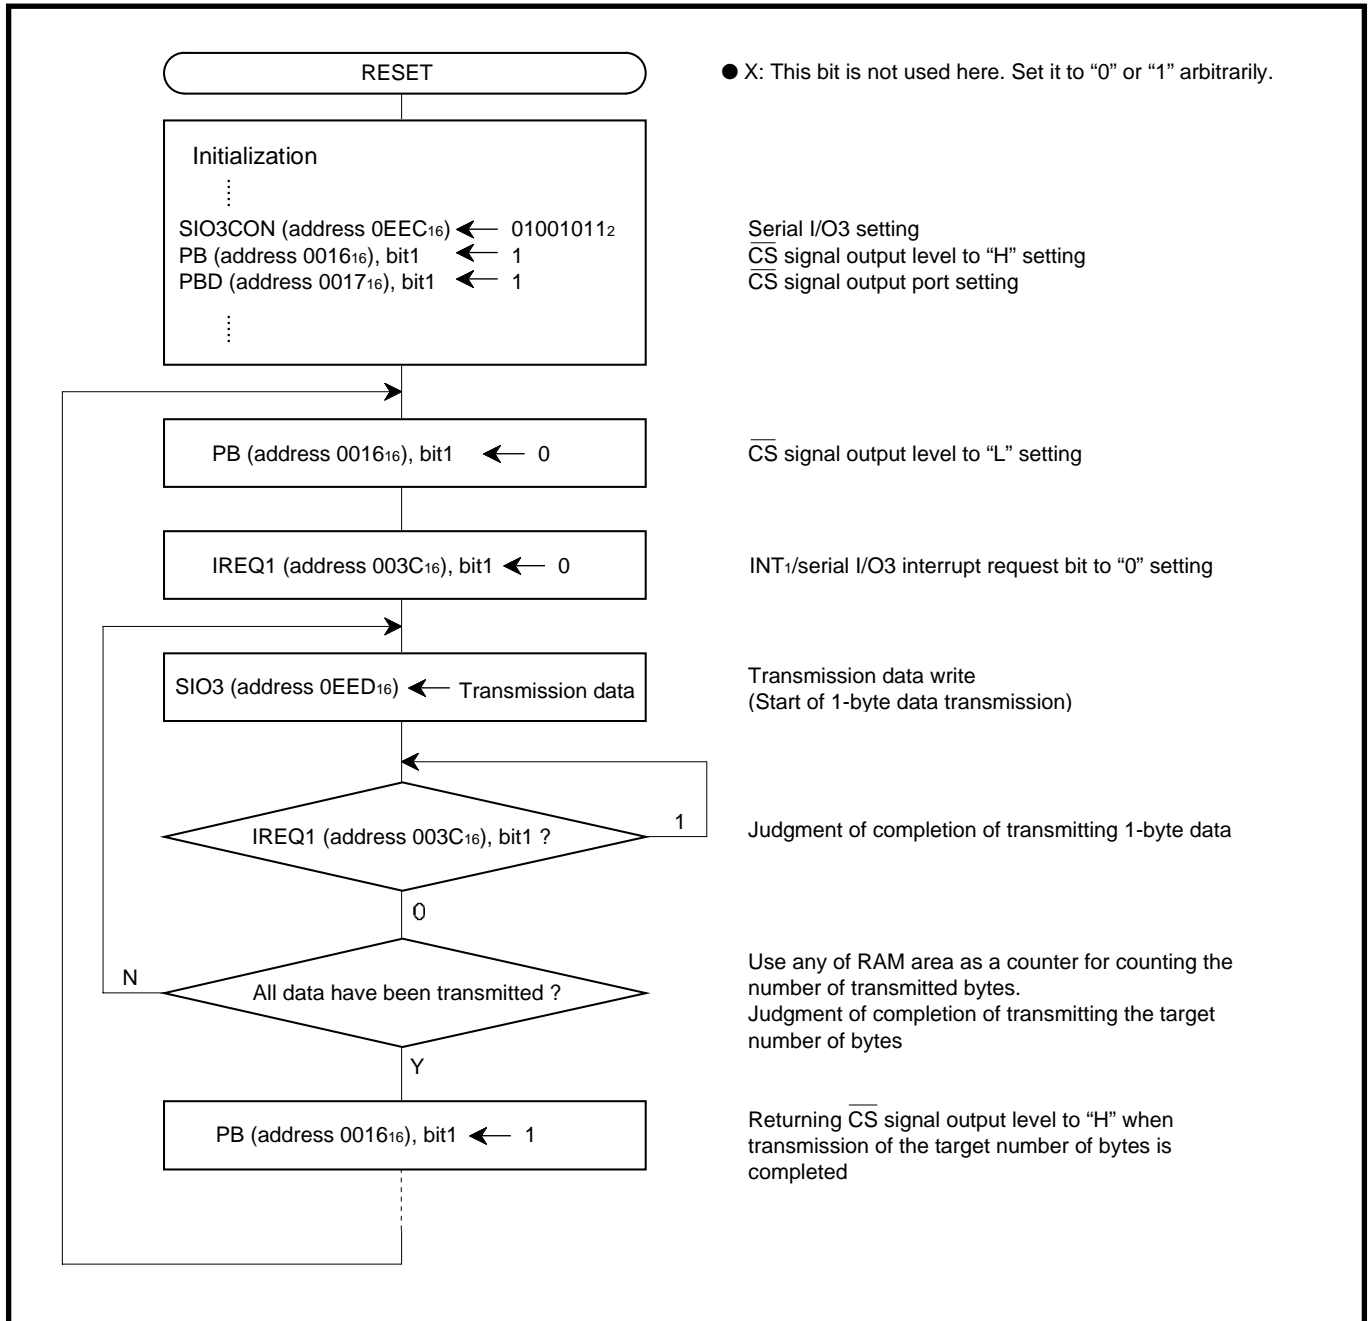

Fig. 2.3.65 Control procedure

## 2.3.12 Notes on serial I/O1

## (1) Clock

## ■ Using internal clock

After setting the synchronous clock to an internal clock, clear the serial I/O interrupt request bit before performing the normal serial I/O transfer or the serial I/O automatic transfer.

## ■ Using external clock

After inputting “H” level to the external clock input pin, clear the serial I/O interrupt request bit before performing the normal serial I/O transfer or the serial I/O automatic transfer.

## (2) Using serial I/O1 interrupt

Clear bit 3 of the interrupt request register 1 to “0” by software before enabling interrupts.

(3) State of S<sub>OUT1</sub> pin

The S<sub>OUT1</sub> pin control bit of the serial I/O1 control register 2 can be used to select the state of the S<sub>OUT1</sub> pin when serial data is not transferred; either output active or high-impedance. However, when selecting an external synchronous clock; the S<sub>OUT1</sub> pin can become the high-impedance state by setting the S<sub>OUT1</sub> pin control bit to “1” when the serial I/O1 clock input is at “H” after transfer completion.

## (4) Serial I/O initialization bit

- Set “0” to the serial I/O initialization bit of the serial I/O1 control register 1 when terminating a serial transfer during transferring.
- When writing “1” to the serial I/O initialization bit, the serial I/O1 is enabled, but each register is not initialized. Set the value of each register by program.

## (5) Handshake signal

■ S<sub>BUSY1</sub> input signal

Input an “H” level to the S<sub>BUSY1</sub> input and an “L” level signal to the  $\overline{S_{BUSY1}}$  input in the initial state. When the external synchronous clock is selected, switch the input level to the S<sub>BUSY1</sub> input and the  $\overline{S_{BUSY1}}$  input while the serial I/O1 clock input is in “H” state.

■ S<sub>RDY1</sub> input•output signal

When selecting the internal synchronous clock, input an “L” level to the S<sub>RDY1</sub> input and an “H” level signal to the  $\overline{S_{RDY1}}$  input in the initial state.

## (6) 8-bit serial I/O mode

## ■ When selecting external synchronous clock

When an external synchronous clock is selected, the contents of the serial I/O1 register are being shifted continually while the transfer clock is input to the serial I/O1 clock pin. In this case, control the clock externally.

## (7) In automatic transfer serial I/O mode

## ■ Set of automatic transfer interval

- When the S<sub>BUSY1</sub> output is used, and the S<sub>BUSY1</sub> output and the S<sub>STB1</sub> output function as signals for each transfer data set by the S<sub>BUSY1</sub> output•S<sub>STB1</sub> output function selection bit of serial I/O1 control register 2; the transfer interval is inserted before the first data is transmitted/received, and after the last data is transmitted/received. Accordingly, regardless of the contents of the S<sub>BUSY1</sub> output•S<sub>STB1</sub> output function selection bit, this transfer interval for each 1-byte data becomes 2 cycles longer than the value set by the automatic transfer interval set bits of serial I/O1 control register 3.

# APPLICATION

## 2.3 Serial I/O

- When using the S<sub>STB1</sub> output, regardless of the contents of the S<sub>BUSY1</sub> output, S<sub>STB1</sub> output function selection bit, this transfer interval for each 1-byte data becomes 2 cycles longer than the value set by the automatic transfer interval set bits of serial I/O1 control register 3.
- When using the combined output of S<sub>BUSY1</sub> and S<sub>STB1</sub> as the signal for each of all transfer data set, the transfer interval after completion of transmission/reception of the last data becomes 2 cycles longer than the value set by the automatic transfer interval set bits.
- When selecting an external clock, the set of automatic transfer interval becomes invalid.
- Set the transfer interval of each 1-byte data transfer as the following:
  - (1) **Not using FLD controller**  
Keep the interval for 5 cycles or more of internal system clock from clock rising of the last bit of 1-byte data.
  - (2) **Using FLD controller**
    - (a) Not using gradation display  
Keep the interval for 17 cycles or more of internal system clock from clock rising of the last bit of 1-byte data.
    - (b) Using gradation display  
Keep the interval for 27 cycles or more of internal system clock from clock rising of the last bit of 1-byte data.

<Serial I/O1 control register 3, SIO1CON3 (address 001C<sub>16</sub>) setting example>

**Table 2.3.2 SIO1CON3 (address 001C<sub>16</sub>) setting example selecting internal synchronous clock**

Serial I/O1 control register 3, SIO1CON3 (address 001C <sub>16</sub> )		Not using FLDC	Not using gradation display mode	Using gradation display mode

0 0 0 : f(X <sub>IN</sub> ) / 4	0 0 0 0 0 : 2 cycles of transfer clocks	Usable	Prohibited	Prohibited
	0 0 0 0 1 : 3 cycles of transfer clocks	Usable	Prohibited	Prohibited
	0 0 0 1 0 : 4 cycles of transfer clocks	Usable	Prohibited	Prohibited
	0 0 0 1 1 : 5 cycles of transfer clocks	Usable	Usable	Usable
0 0 1 : f(X <sub>IN</sub> ) / 8	0 0 0 0 0 : 2 cycles of transfer clocks	Usable	Prohibited	Prohibited
	0 0 0 0 1 : 3 cycles of transfer clocks	Usable	Usable	Usable
0 1 0 : f(X <sub>IN</sub> ) / 16	0 0 0 0 0 : 2 cycles of transfer clocks	Usable	Usable	Usable

**Table 2.3.3 SIO1CON3 (address 001C<sub>16</sub>) setting example selecting external synchronous clock**

Serial I/O1 control register 3, SIO1CON3 (address 001C <sub>16</sub> ), Automatic transfer interval set bits	"n" cycles of transfer clocks
Not using FLDC	Transfer clock X n cycles ≥ 5 cycles of internal system clock
Not using gradation display mode	Transfer clock X n cycles ≥ 17 cycles of internal system clock
Using gradation display mode	Transfer clock X n cycles ≥ 27 cycles of internal system clock

### ■ Set of serial I/O1 transfer counter

- Write the value decreased by 1 from the number of transfer data bytes to the serial I/O1 transfer counter.
- When selecting an external clock, after writing a value to the serial I/O1 register/transfer counter, wait for 5 or more cycles of internal system clock before inputting the transfer clock to the serial I/O1 clock pin.

### ■ Serial I/O initialization bit

A serial I/O1 automatic transfer interrupt request occurs when "0" is written to the serial I/O initialization bit during an operation. Disable it with the interrupt enable bit as necessary by program.

### 2.3.13 Notes on serial I/O2

#### (1) Notes when selecting clock synchronous serial I/O

##### ① Stop of transmission operation

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, clear the transmit enable bit to "0" (transmit disabled).

##### ● Reason

Since transmission is not stopped and the transmission circuit is not initialized even if only the serial I/O2 enable bit is cleared to "0" (serial I/O2 disabled), the internal transmission is running (in this case, since pins TxD, RxD, S<sub>CLK21</sub>, S<sub>CLK22</sub> and  $\overline{S}_{RDY2}$  function as I/O ports, the transmission data is not output). When data is written to the transmit buffer register in this state, data starts to be shifted to the transmit shift register. When the serial I/O2 enable bit is set to "1" at this time, the data during internally shifting is output to the TxD pin and an operation failure occurs.

##### ② Stop of receive operation

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, clear the receive enable bit to "0" (receive disabled), or clear the serial I/O2 enable bit to "0" (serial I/O2 disabled).

##### ③ Stop of transmit/receive operation

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, simultaneously clear both the transmit enable bit and receive enable bit to "0" (transmit and receive disabled).

(when data is transmitted and received in the clock synchronous serial I/O mode, any one of data transmission and reception cannot be stopped.)

##### ● Reason

In the clock synchronous serial I/O mode, the same clock is used for transmission and reception. If any one of transmission and reception is disabled, a bit error occurs because transmission and reception cannot be synchronized.

In this mode, the clock circuit of the transmission circuit also operates for data reception. Accordingly, the transmission circuit does not stop by clearing only the transmit enable bit to "0" (transmit disabled). Also, the transmission circuit is not initialized by clearing the serial I/O2 enable bit to "0" (serial I/O2 disabled) (refer to (1), ①).

# APPLICATION

## 2.3 Serial I/O

### (2) Notes when selecting clock asynchronous serial I/O

#### ① Stop of transmission operation

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, clear the transmit enable bit to "0" (transmit disabled).

#### ● Reason

Since transmission is not stopped and the transmission circuit is not initialized even if only the serial I/O2 enable bit is cleared to "0" (serial I/O2 disabled), the internal transmission is running (in this case, since pins TxD, RxD, S<sub>CLK21</sub>, S<sub>CLK22</sub> and  $\overline{S_{RDY2}}$  function as I/O ports, the transmission data is not output). When data is written to the transmit buffer register in this state, data starts to be shifted to the transmit shift register. When the serial I/O2 enable bit is set to "1" at this time, the data during internally shifting is output to the TxD pin and an operation failure occurs.

#### ② Stop of receive operation

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, clear the receive enable bit to "0" (receive disabled).

#### ③ Stop of transmit/receive operation

##### Only transmission operation is stopped.

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, clear the transmit enable bit to "0" (transmit disabled).

#### ● Reason

Since transmission is not stopped and the transmission circuit is not initialized even if only the serial I/O2 enable bit is cleared to "0" (serial I/O2 disabled), the internal transmission is running (in this case, since pins TxD, RxD, S<sub>CLK21</sub>, S<sub>CLK22</sub> and  $\overline{S_{RDY2}}$  function as I/O ports, the transmission data is not output). When data is written to the transmit buffer register in this state, data starts to be shifted to the transmit shift register. When the serial I/O2 enable bit is set to "1" at this time, the data during internally shifting is output to the TxD pin and an operation failure occurs.

##### Only receive operation is stopped.

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, clear the receive enable bit to "0" (receive disabled).

### (3) $\overline{S_{RDY2}}$ output of reception side

When signals are output from the  $\overline{S_{RDY2}}$  pin on the reception side by using an external clock in the clock synchronous serial I/O mode, set all of the receive enable bit, the  $\overline{S_{RDY2}}$  output enable bit, and the transmit enable bit to "1" (transmit enabled).

### (4) Setting serial I/O2 control register again

Set the serial I/O2 control register again after the transmission and the reception circuits are reset by clearing both the transmit enable bit and the receive enable bit to "0."

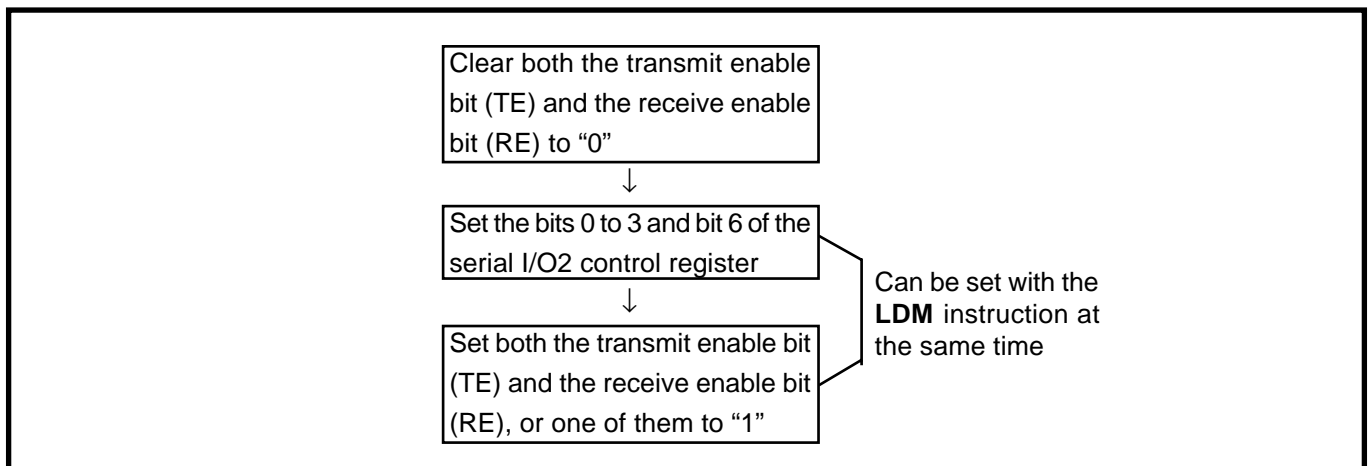

Fig. 2.3.66 Sequence of setting serial I/O2 control register again

**(5) Data transmission control with referring to transmit shift register completion flag**

The transmit shift register completion flag changes from “1” to “0” with a delay of 0.5 to 1.5 shift clocks. When data transmission is controlled with referring to the flag after writing the data to the transmit buffer register, note the delay.

**(6) Transmission control when external clock is selected**

When an external clock is used as the synchronous clock for data transmission, set the transmit enable bit to “1” at “H” of the serial I/O2 clock input level. Also, write the transmit data to the transmit buffer register (serial I/O shift register) at “H” of the serial I/O2 clock input level.

**(7) Setting procedure when serial I/O2 transmit interrupt is used**

When setting the transmit enable bit to “1”, the serial I/O2 transmit interrupt request bit is automatically set to “1”. When not requiring the interrupt occurrence synchronized with the transmission enabled, take the following sequence.

- ①Set the serial I/O1 transmit interrupt enable bit to “0” (disabled).
- ②Set the transmit enable bit to “1”.
- ③Set the serial I/O1 transmit interrupt request bit to “0” after 1 or more instructions have been executed.
- ④Set the serial I/O1 transmit interrupt enable bit to “1” (enabled).

**(8) Using TxD pin**

The P6<sub>s</sub>/TxD P-channel output disable bit of UART control register is valid in both cases: using as a normal I/O port and as the TxD pin. Do not supply  $V_{cc} + 0.3$  V or more even when using the P6<sub>s</sub>/TxD pin as an N-channel open-drain output.

Additionally, in the serial I/O2, the TxD pin latches the last bit and continues to output it after completing transmission.

#### (1) Key-scan using FLD automatic display and segments

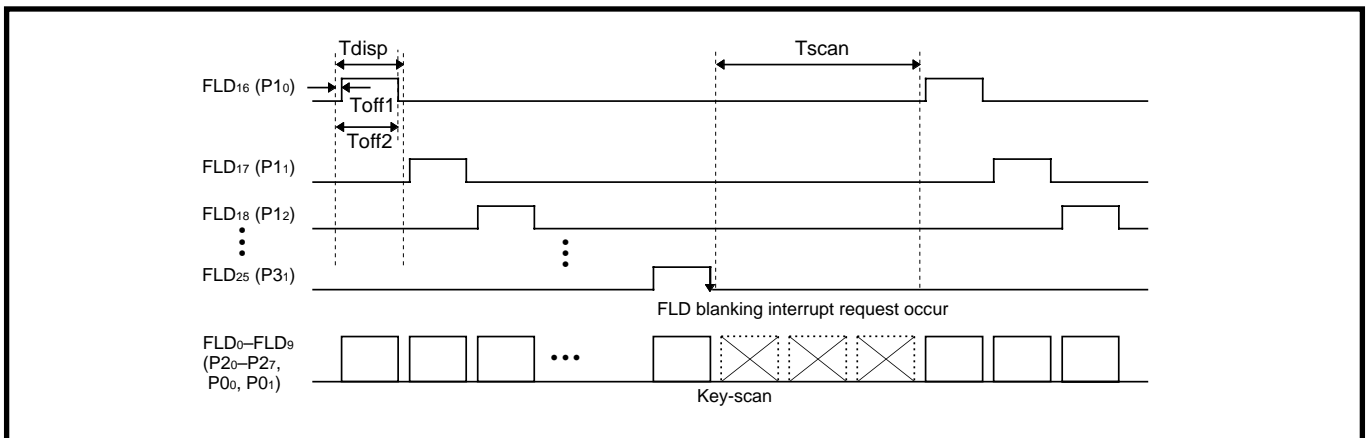

**Outline:** Key read-in with segment pins is performed by software using the FLD automatic display mode.

**Fig. 2.4.15 Connection diagram**

- Specifications:**
- Use of total 20 FLD ports (10 digits; 10 segments (8 key-scan included))
  - Use of FLD automatic display mode
  - Display in gradation display mode and 16 timing mode
  - $T_{off1} = 40 \mu s$ ,  $T_{off2} = 64 \mu s$ ,  $T_{disp} = 204 \mu s$ ,  $T_{scan} = 3 \times T_{disp} = 612 \mu s$ ,  $f(X_{IN}) = 4 \text{ MHz}$
  - Use of FLD blanking interrupt

Figure 2.4.16 shows the timing chart of key-scan, and Figure 2.4.17 shows the enlarged view of  $T_{scan}$ . After switching the segment pin to an output port, generate the waveform shown Figure 2.4.17 by software and perform key-scan.

# APPLICATION

## 2.4 FLD controller

Control procedure:

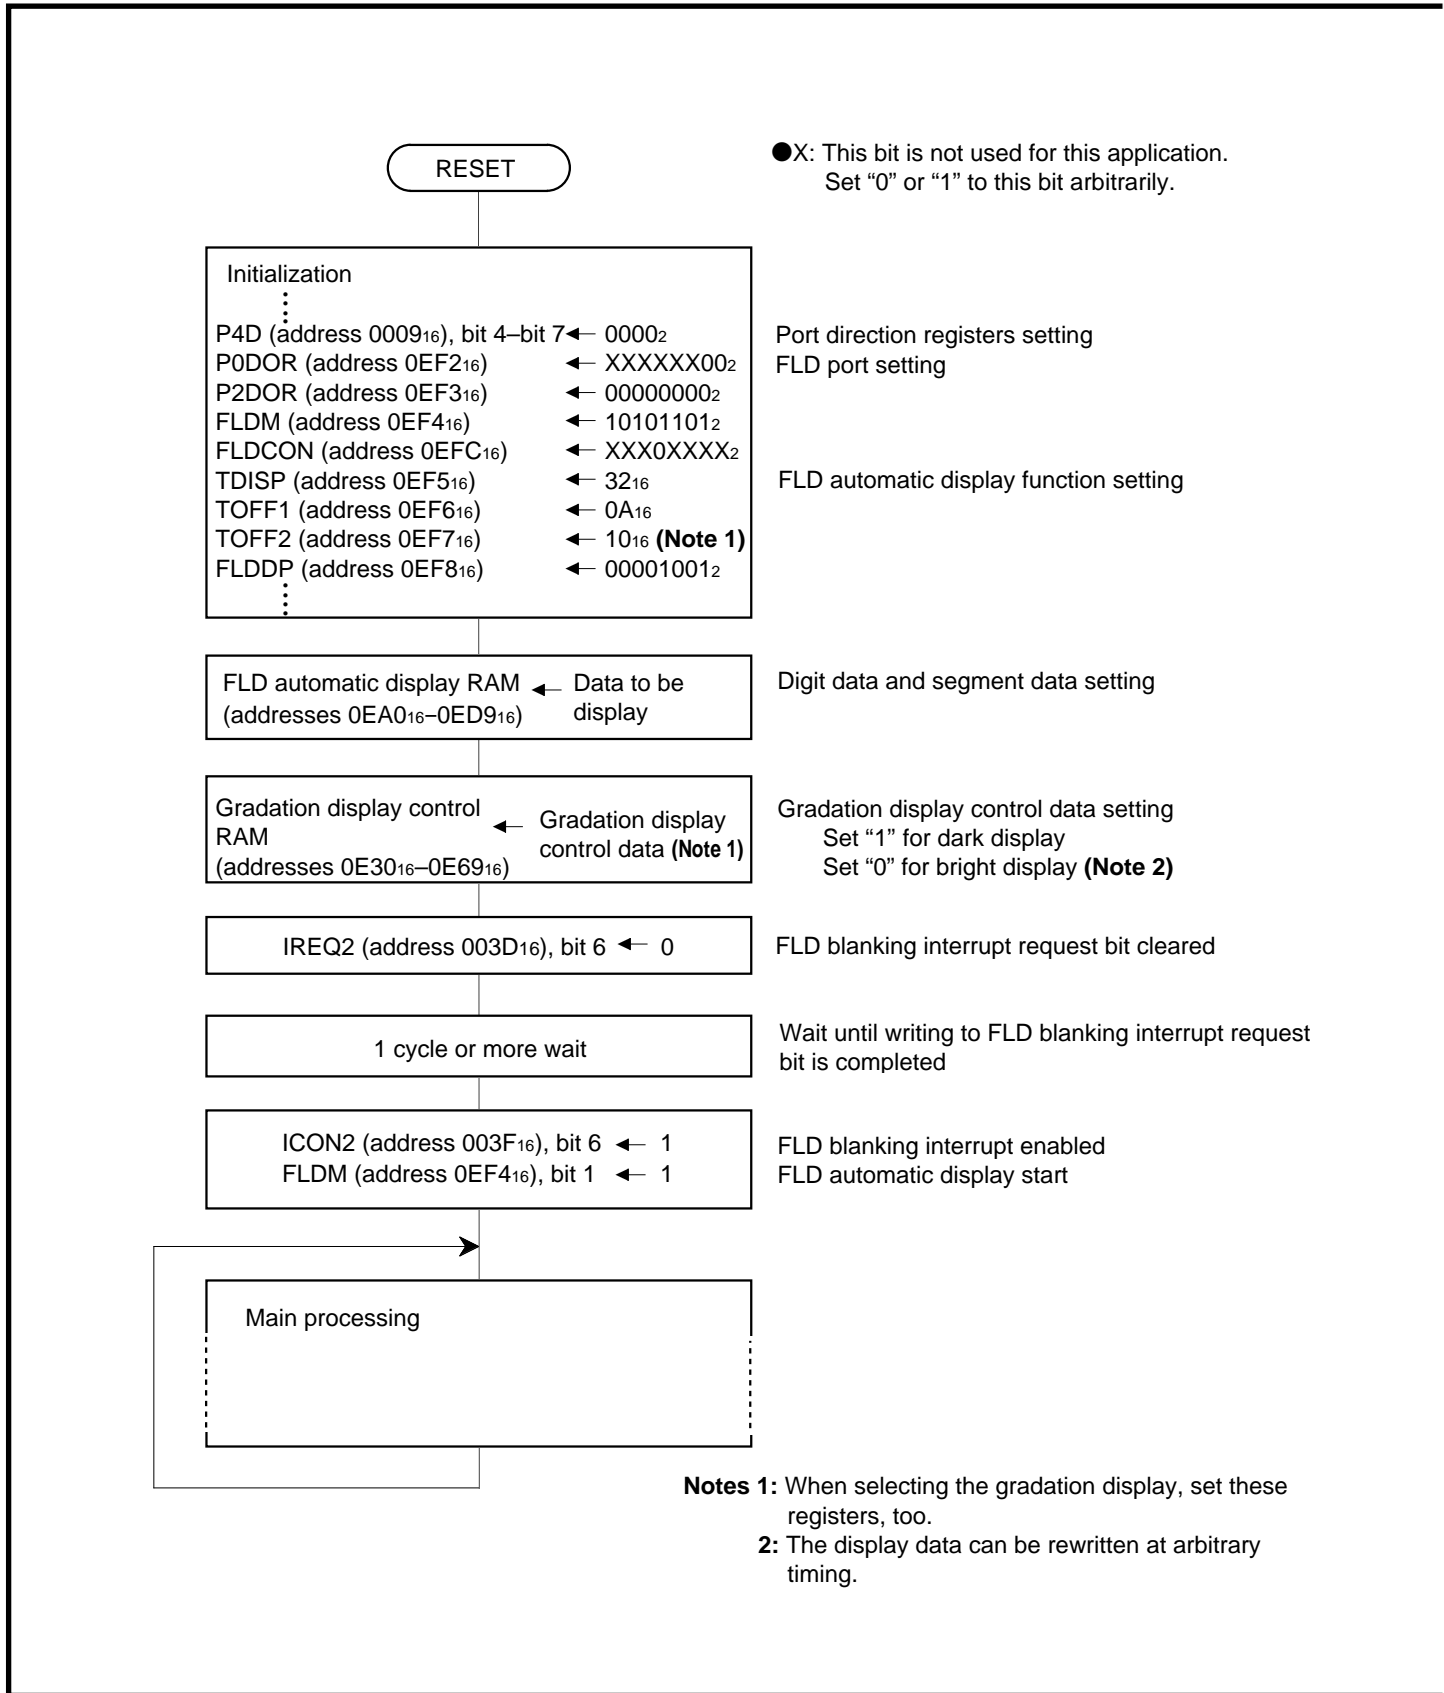

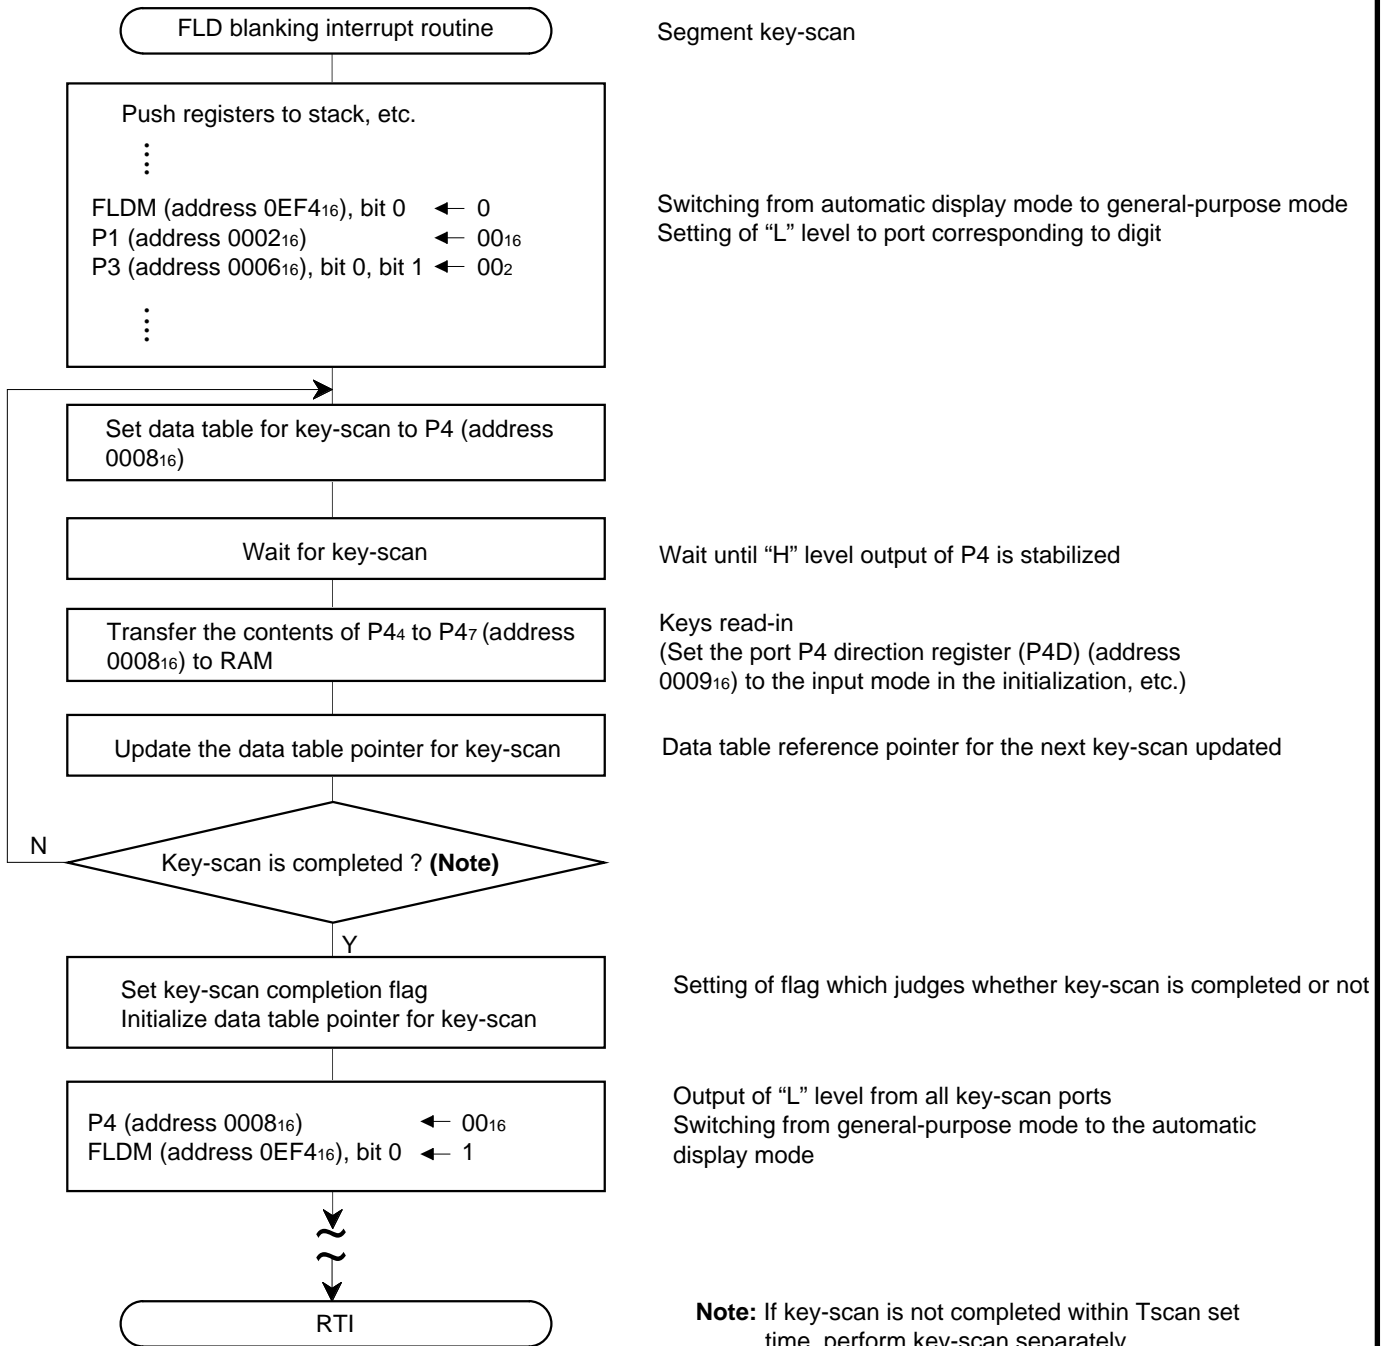

Fig. 2.4.20 Control procedure

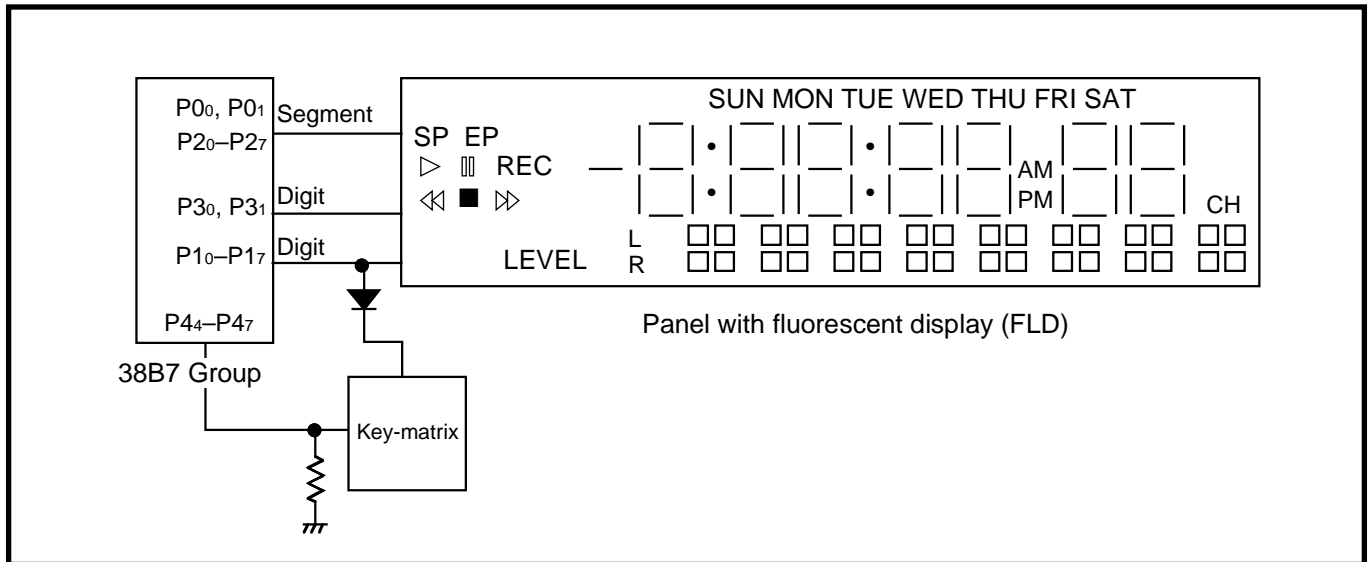

# APPLICATION

## 2.4 FLD controller

### (2) Key-scan using FLD automatic display and digits

**Outline:** Key read-in with digit output waveforms is performed by software using the FLD automatic display mode.

**Fig. 2.4.21 Connection diagram**

- Specifications:**
- Use of total 20 FLD ports (10 digits, 8 key-scan included; 10 segments)
  - Use of FLD automatic display mode
  - Display in gradation display mode and 16 timing mode
  - $T_{off1} = 40 \mu s$ ,  $T_{off2} = 64 \mu s$ ,  $T_{disp} = 204 \mu s$ ,  $T_{scan} = 0 \mu s$ ,  $f(X_{IN}) = 4 \text{ MHz}$
  - Use of FLD digit interrupt

Figure 2.4.22 shows the timing chart of key-scan.

**Fig. 2.4.22 Timing chart of key-scan using FLD automatic display mode and digits**

# APPLICATION

## 2.4 FLD controller

Figure 2.4.23 shows the setting of relevant registers.

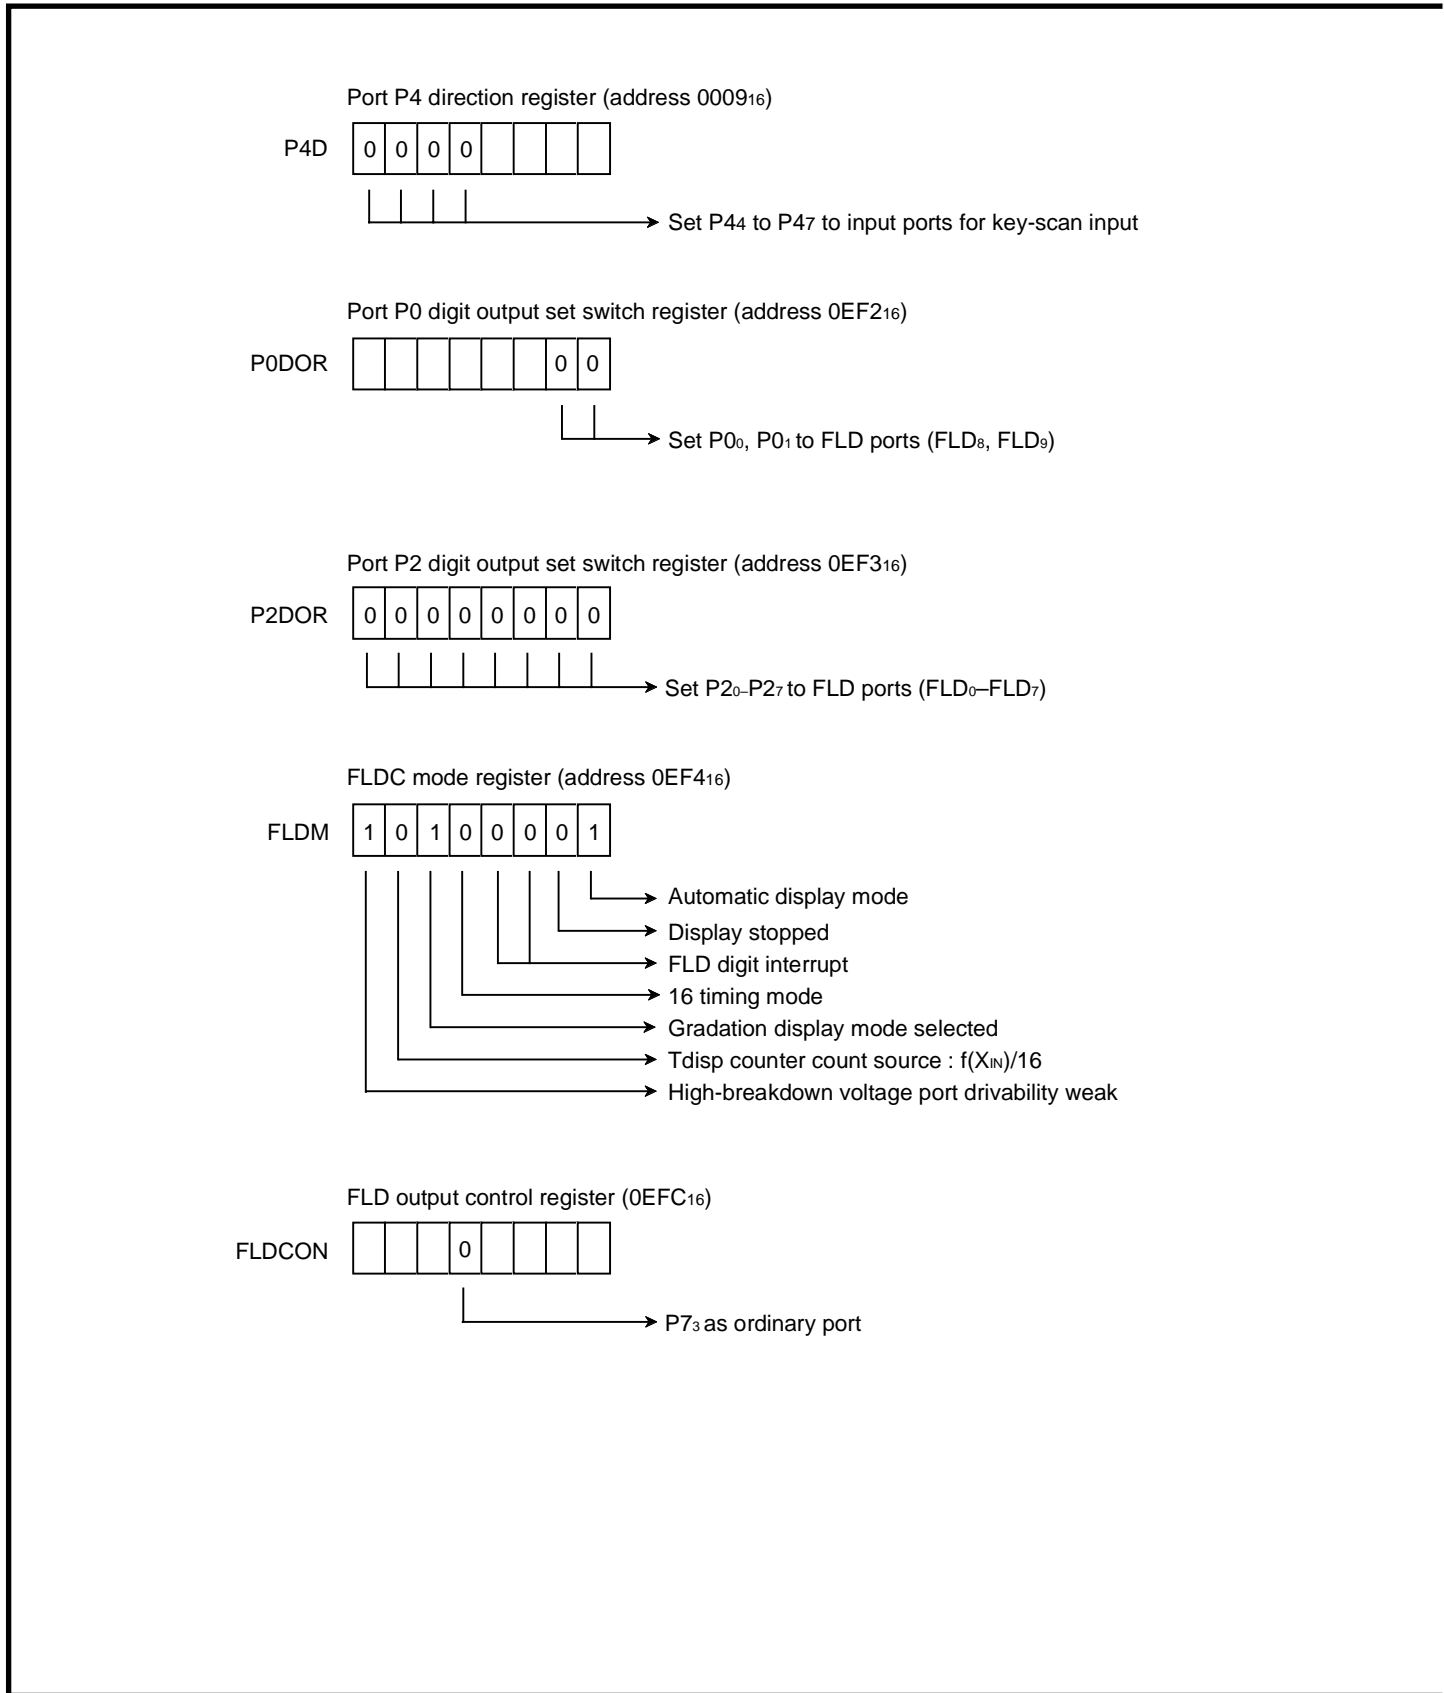

Fig. 2.4.23 Setting of relevant registers

	Tdisp time set register (address 0EF5 <sub>16</sub> )		
TDISP	<table border="1" style="display: inline-table; vertical-align: middle;"><tr><td style="text-align: center;">32<sub>16</sub></td></tr></table>	32 <sub>16</sub>	50 (32 <sub>16</sub> ) set; (50 + 1) X count source = 204 μs Count source = f(X <sub>IN</sub> )/16 = 4 μs, at f(X <sub>IN</sub> ) = 4 MHz
32 <sub>16</sub>			
	Toff1 time set register (address 0EF6 <sub>16</sub> )

## 2.4 FLD controller

Control procedure:

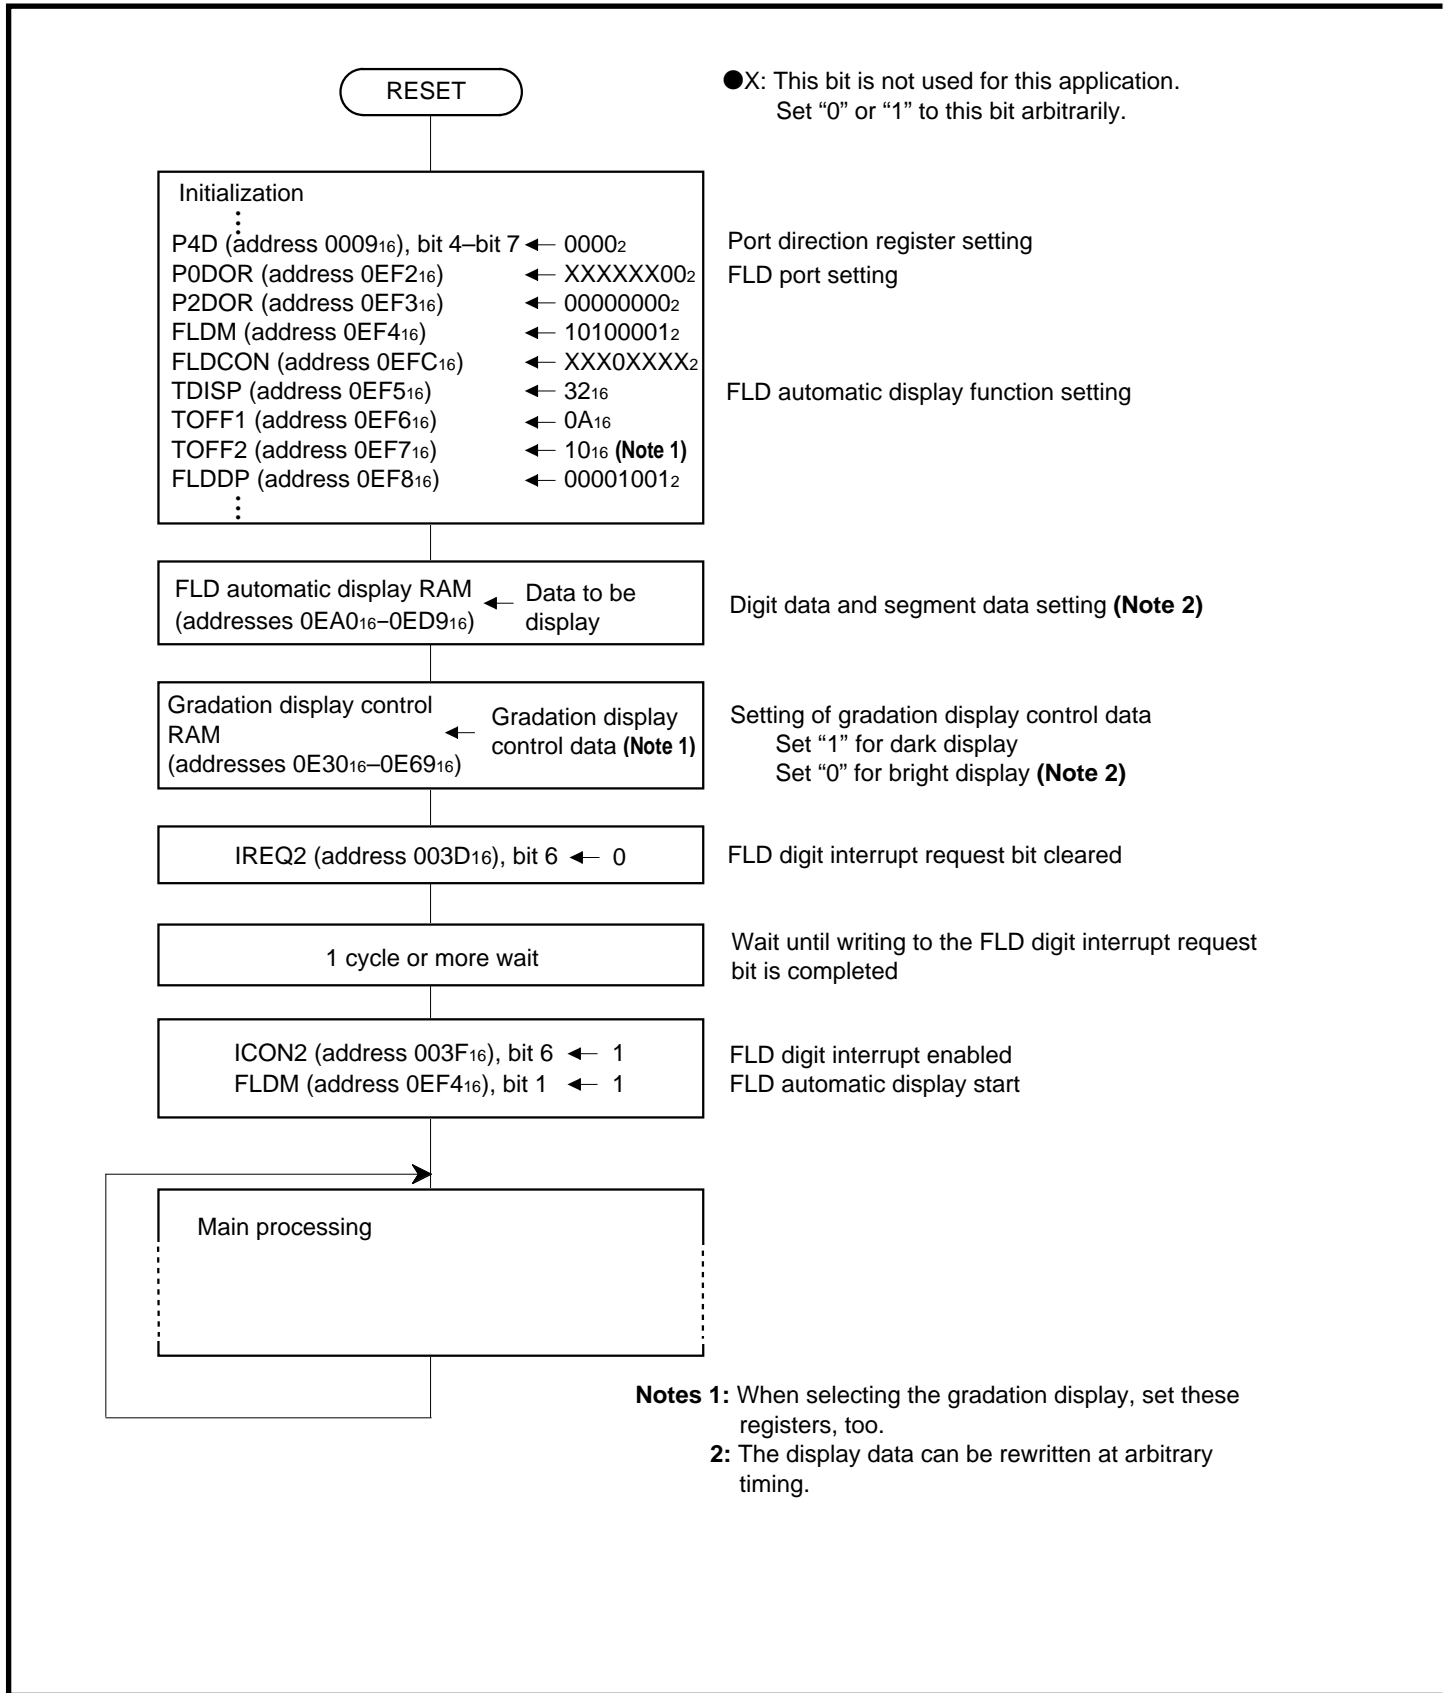

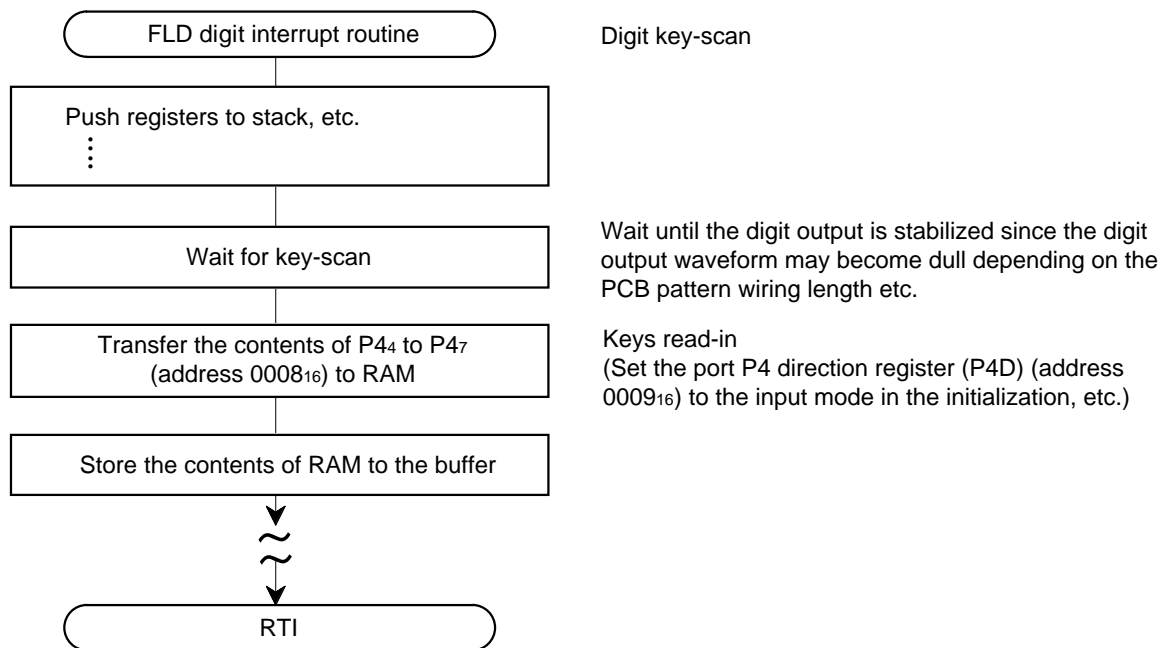

Fig. 2.4.25 Control procedure

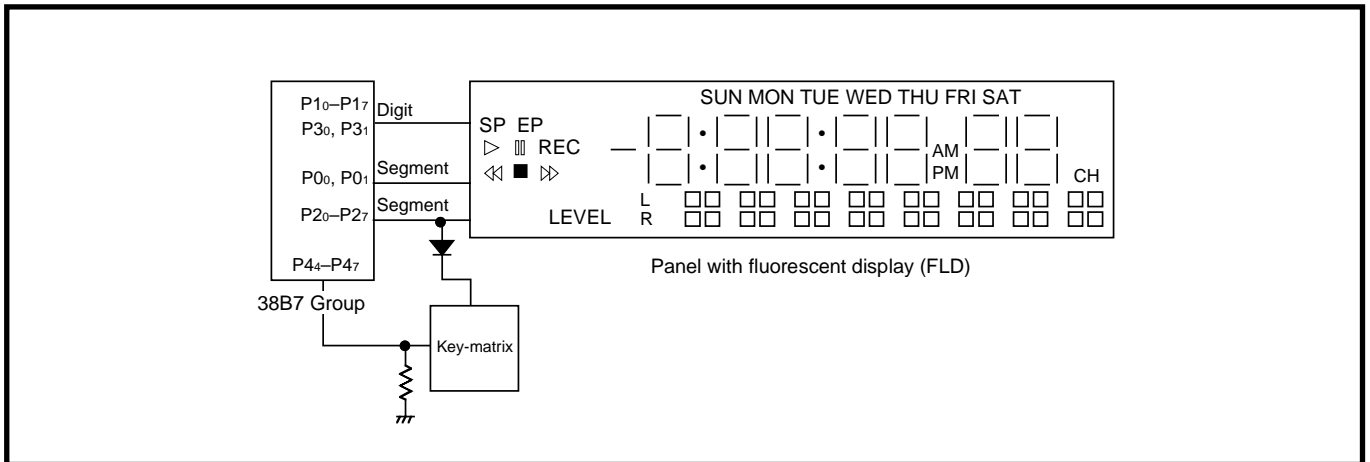

# APPLICATION

## 2.4 FLD controller

### (3) FLD display by software (example of not used FLD controller)

**Outline:** FLD display and key read-in is performed, using a timer interrupt.

**Fig. 2.4.26 Connection diagram**

- Specifications:**
- Use of 10 digits and 10 segments (8 key-scan included)
  - Display controlled by software
  - Use of timer 1 interrupt

Figure 2.4.27 shows the timing chart of FLD display by software, and Figure 2.4.28 shows the enlarged view of P20 to P27 key-scan. Generate the waveform shown in Figure 2.4.28 by software and perform key-scan.

**Fig. 2.4.27 Timing chart of FLD display by software**

(The automatic display is not performed because FLD controller is not used.)

### Control procedure:

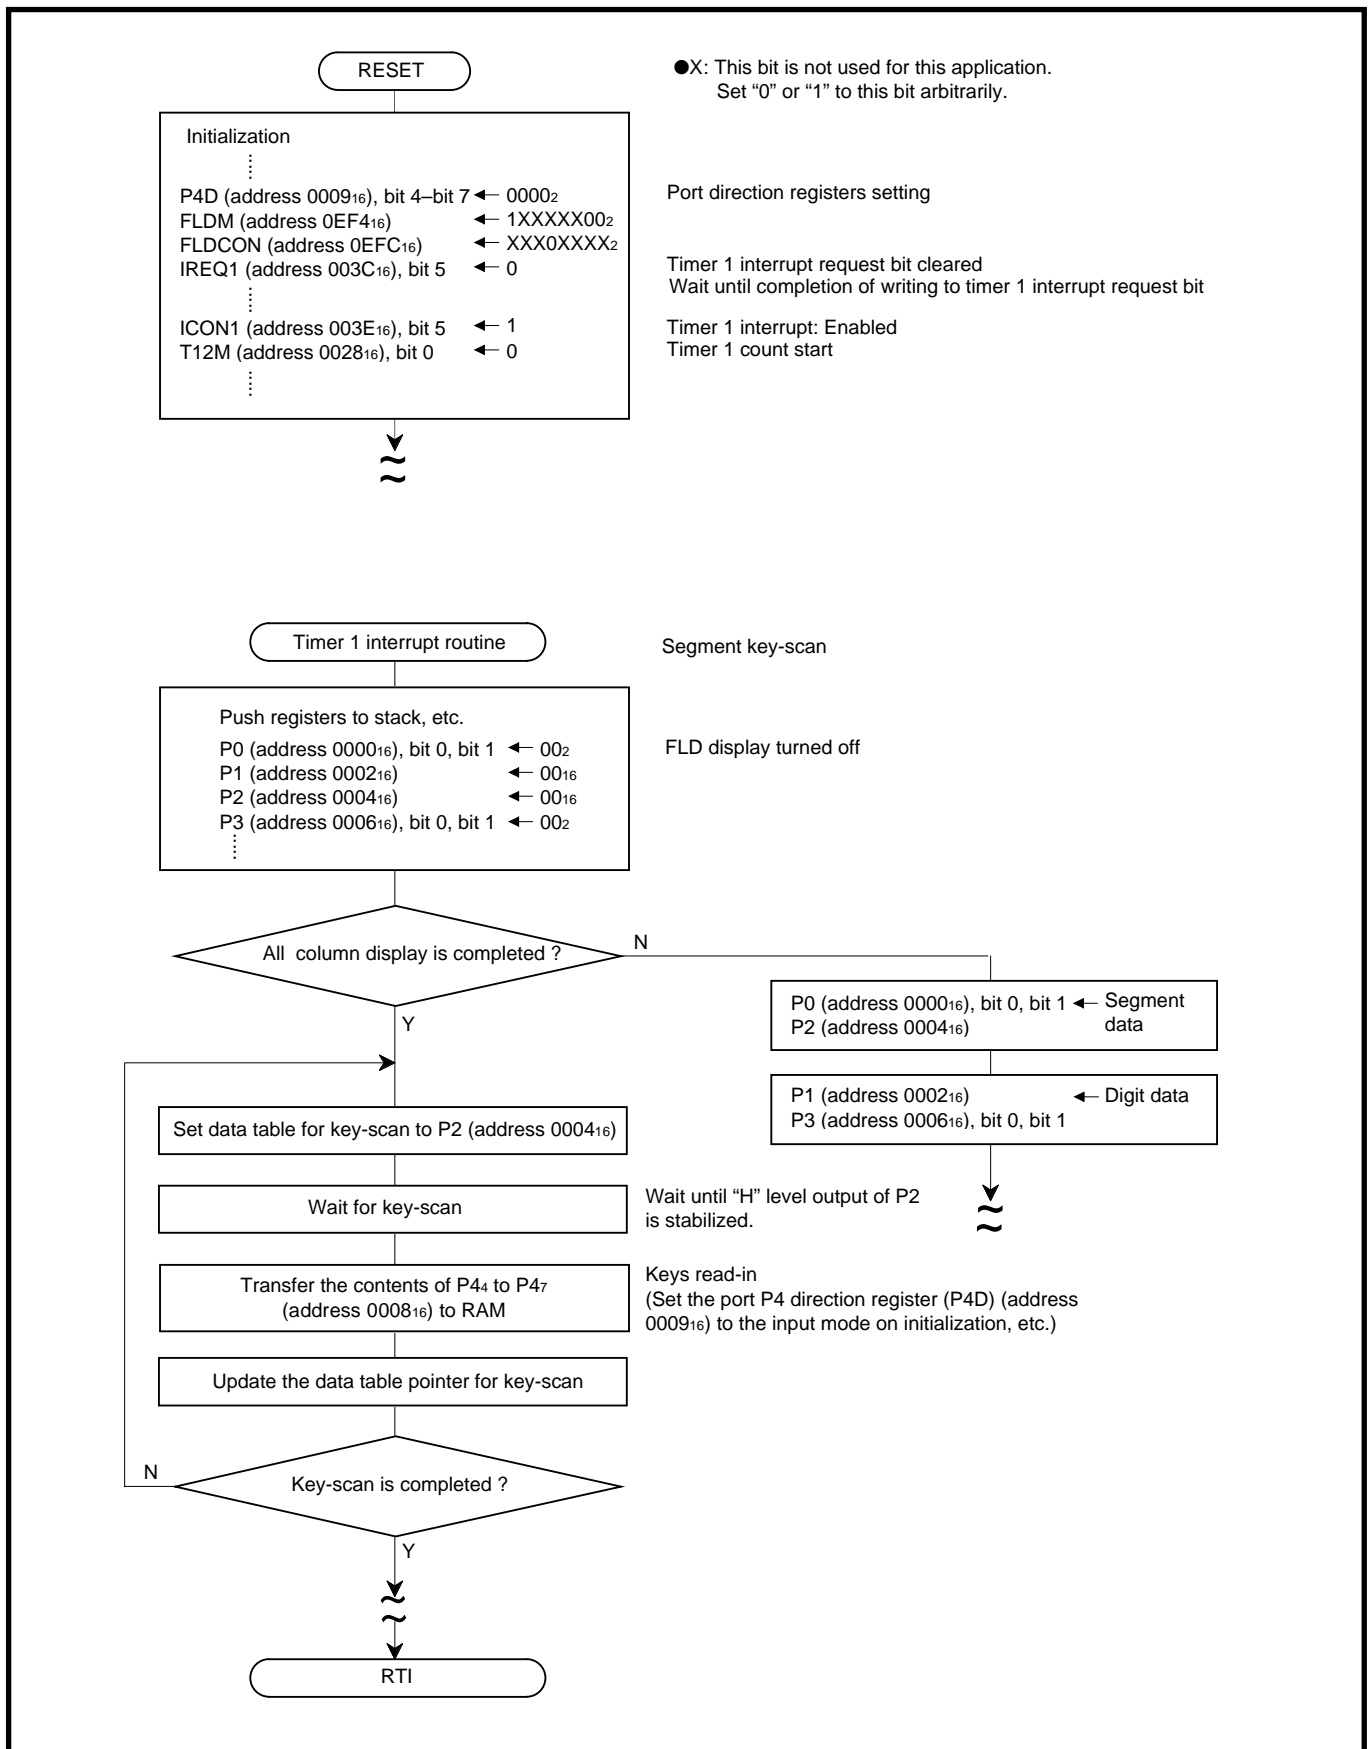

Fig. 2.4.31 Control procedure

# APPLICATION

## 2.4 FLD controller

### (4) Display by combination with digit expander (M35501FP\*) (basic combination example)

\* For M35501FP, refer to section “3.9 M35501FP”.

**Outline:** The fluorescent display which has many display numbers (36 segments × 16 digits) is displayed by using the digit expander (M35501FP).

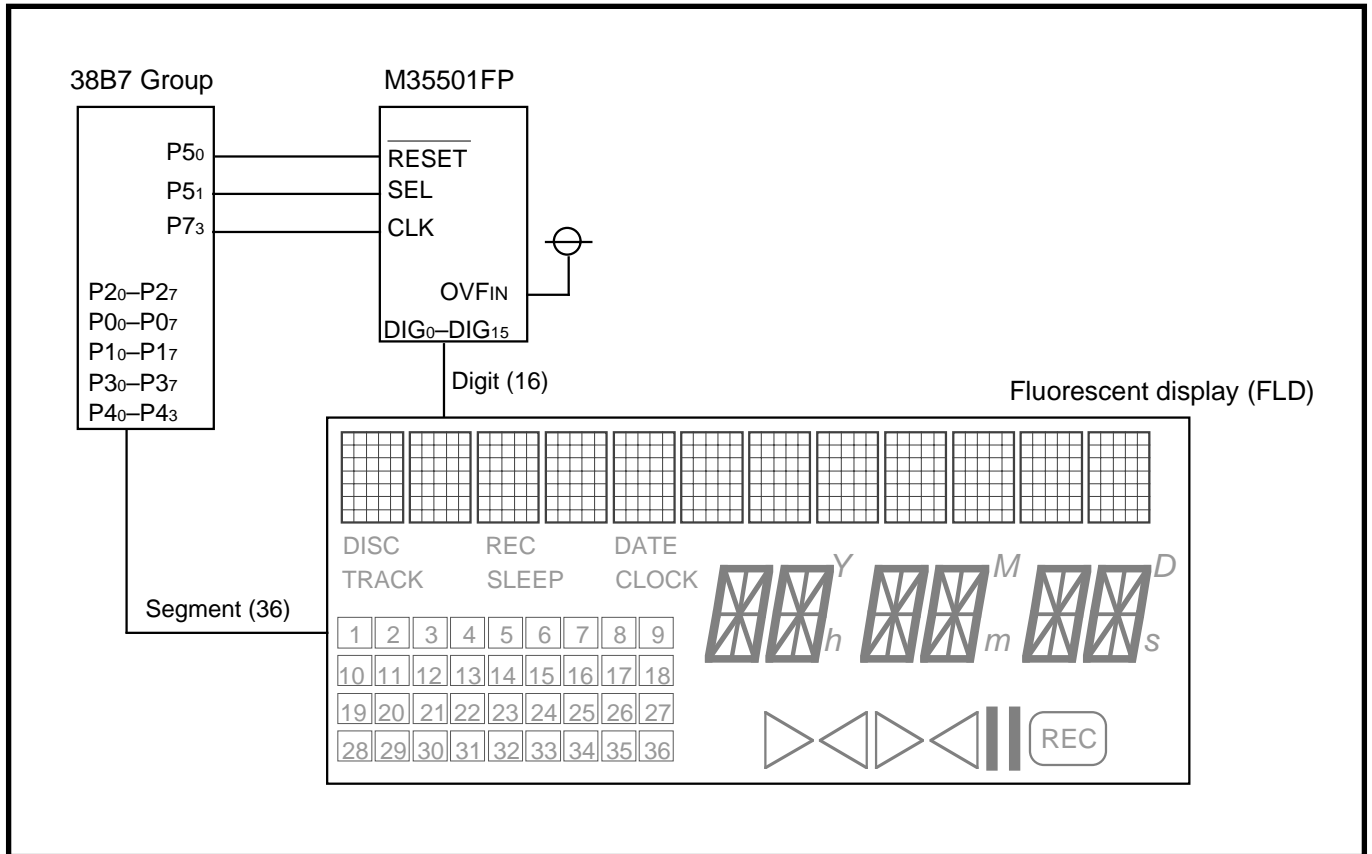

Fig. 2.4.32 Connection diagram

- Specifications:**
- Use of M35501FP (M35501FP: 16 digits, 38B7 Group: 36 segments)  
Ports P5<sub>0</sub> and P5<sub>1</sub> of 38B7 Group supply signals to the RESET and SEL pins of M35501FP respectively.  
The P7<sub>3</sub> pin (dimmer output pin) supply signals to the CLK pin of M35501FP.
  - Use of FLD automatic display mode of 38B7 Group
  - Display in gradation display mode and 16 timing mode
  - Toff1 = 40 μs, Toff2 = 64 μs, Tdisp = 204 μs, f(X<sub>IN</sub>) = 4 MHz

Figure 2.4.33 shows the timing chart of 38B7 Group and M35501FP, and Figure 2.4.34 shows the timing chart (enlarged view) of digit and segment output.

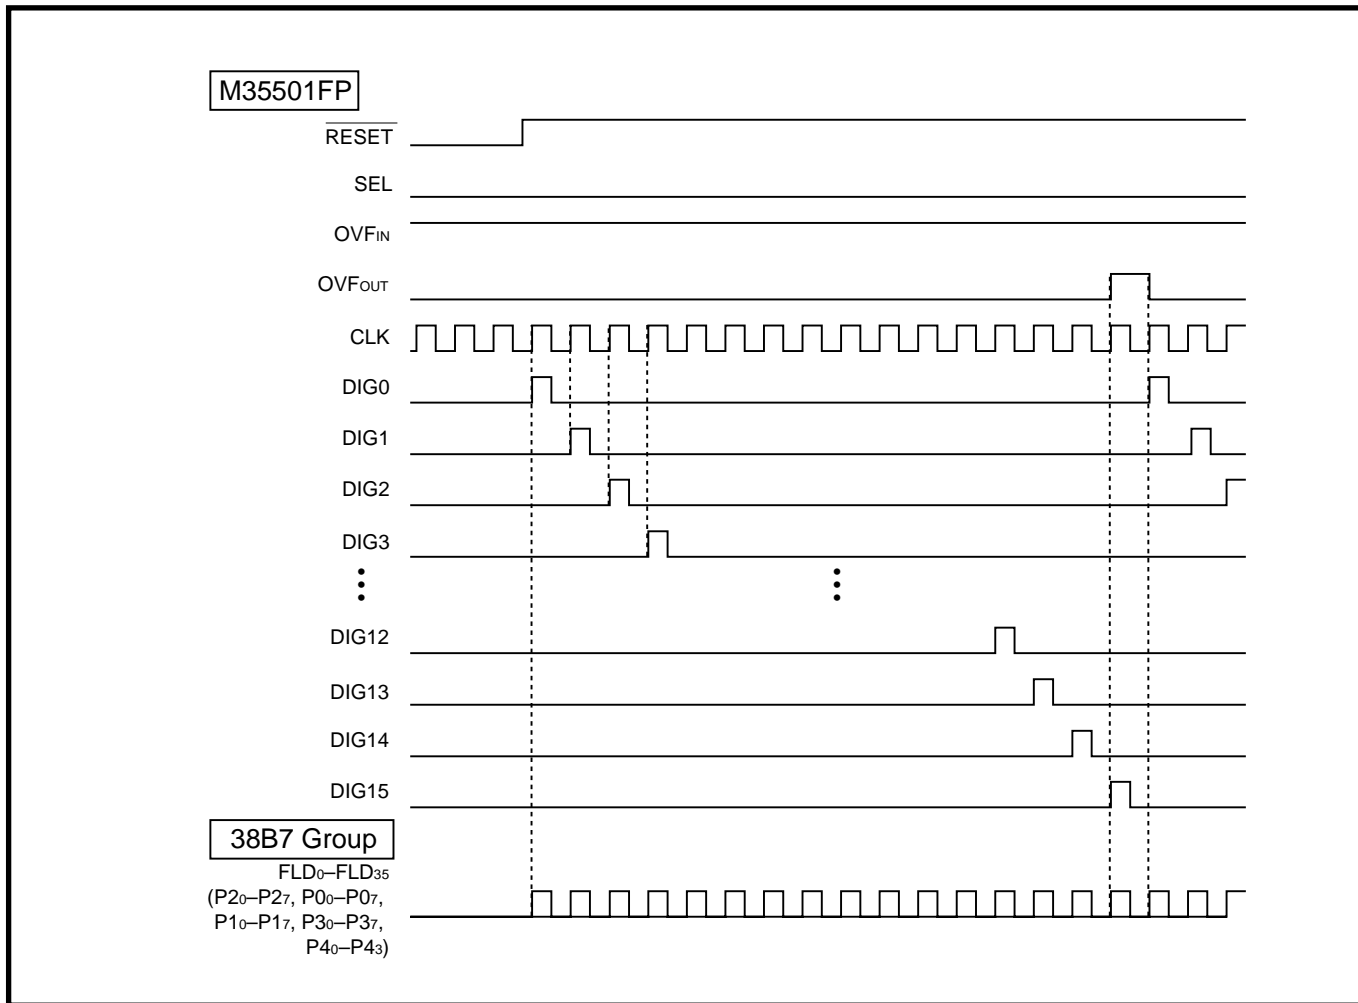

Fig. 2.4.33 Timing chart of 38B7 Group and M35501FP

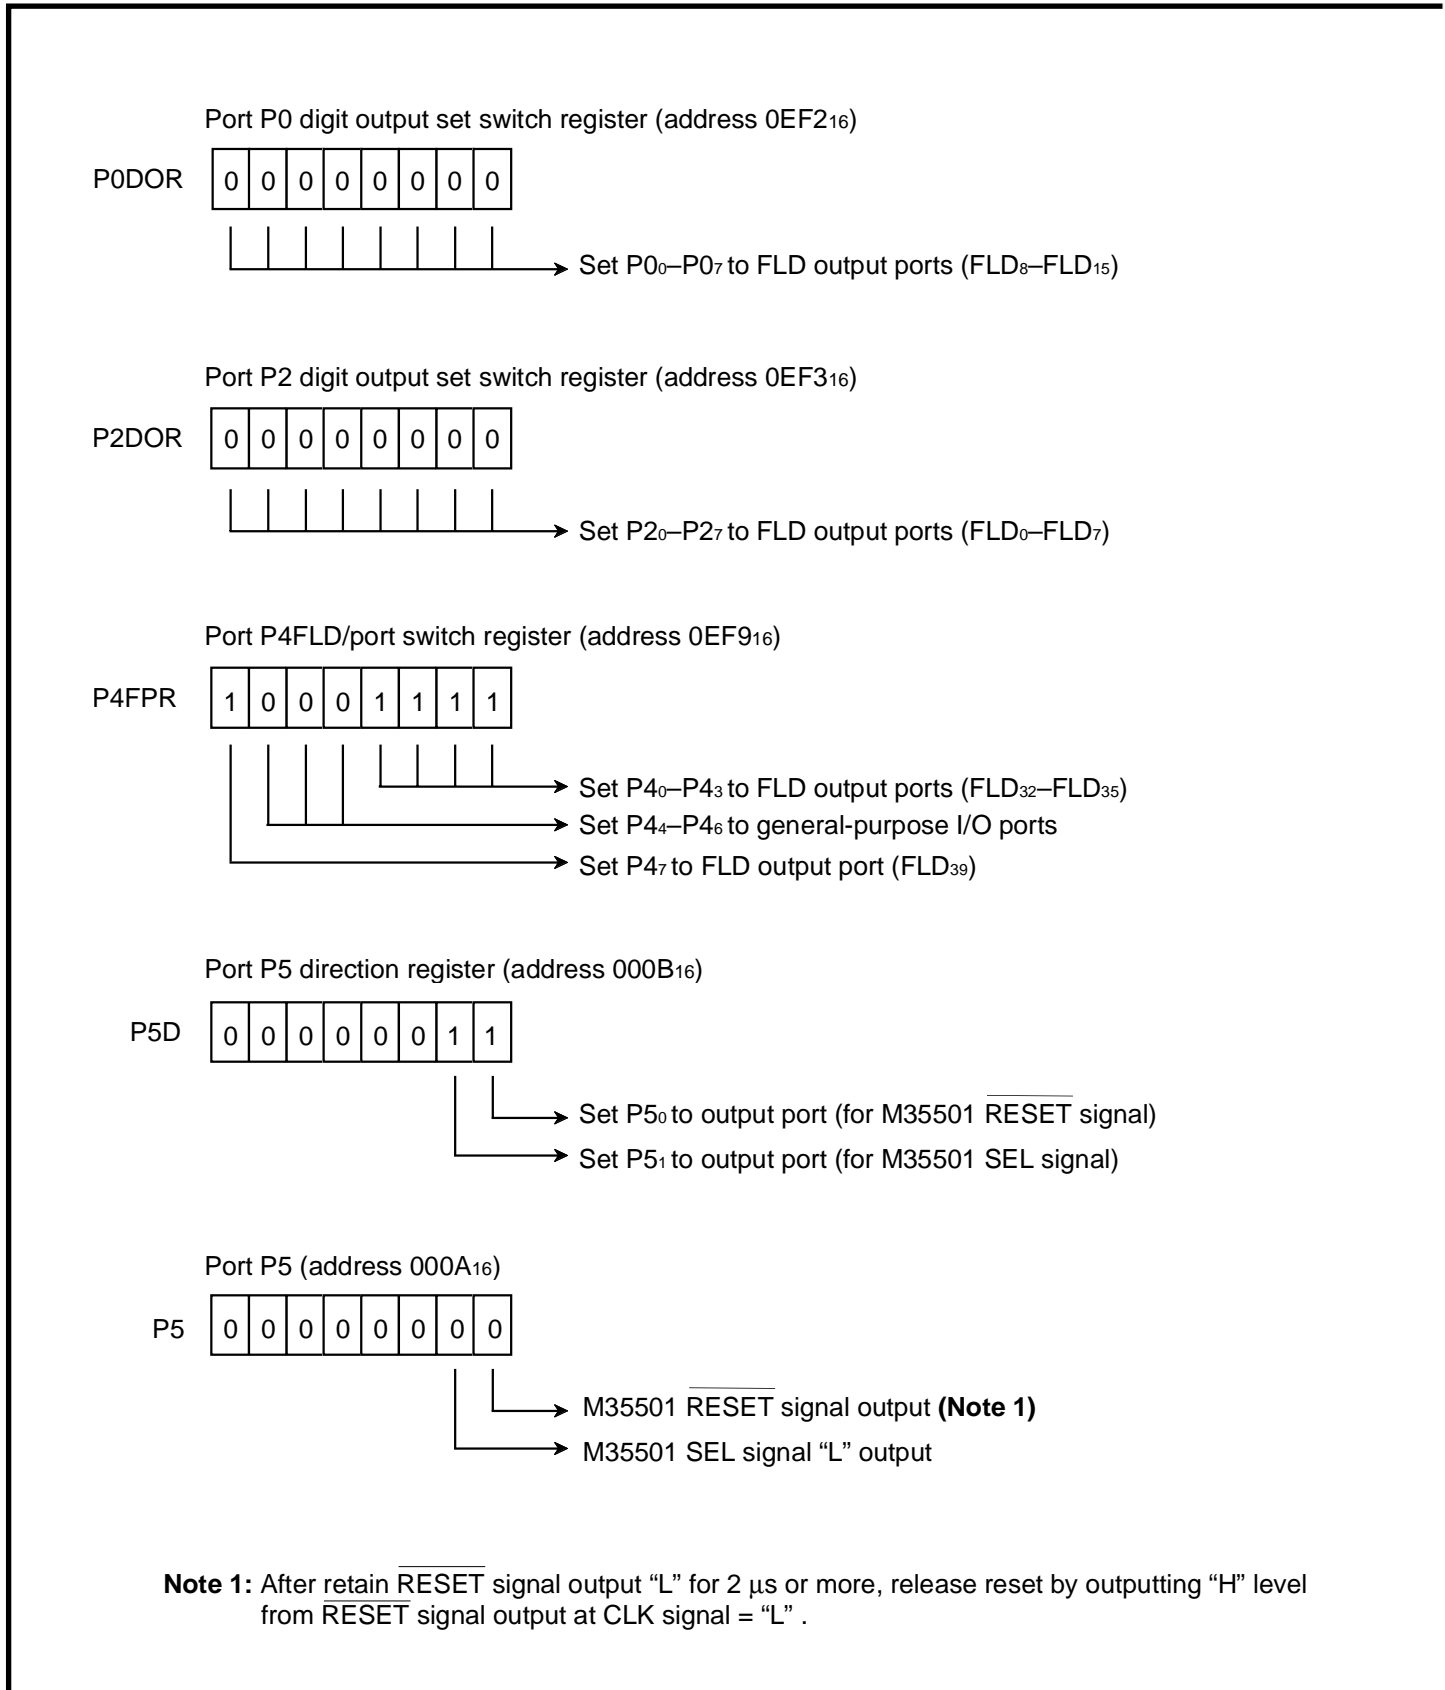

Fig. 2.4.34 Timing chart (enlarged view) of digit and segment output

# APPLICATION

## 2.4 FLD controller

Figure 2.4.35 shows the setting of relevant registers.

**Note 1:** After retain  $\overline{\text{RESET}}$  signal output "L" for 2  $\mu\text{s}$  or more, release reset by outputting "H" level from  $\overline{\text{RESET}}$  signal output at CLK signal = "L".

Fig. 2.4.35 Setting of relevant registers

 : Unused

Fig. 2.4.36 FLD digit allocation example

### Control procedure:

Figure 2.4.37 shows the control procedure.

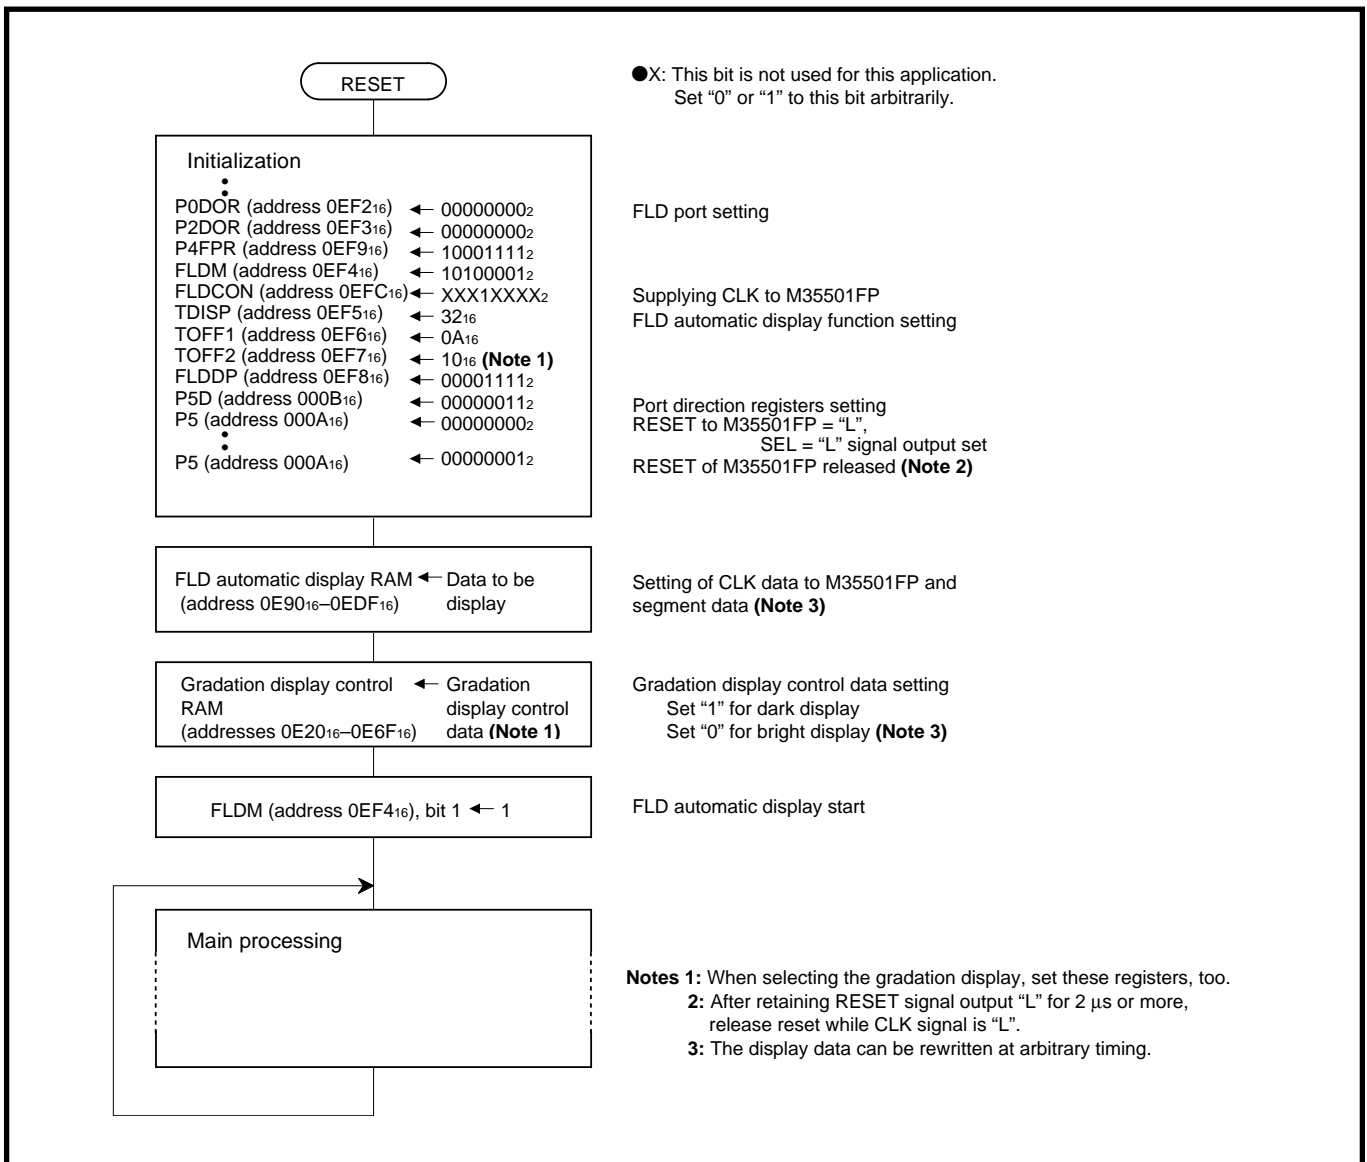

Fig. 2.4.37 Control procedure

# APPLICATION

## 2.4 FLD controller

### (5) Display by combination with digit expander (M35501FP\*) (example considering column discrepancy prevention)

\* For M35501FP, refer to section “3.9 M35501FP”.

**Outline:** In the case of (4), which is displayed by using the digit expander (M35501FP), if a noise enters signals between 38B7 Group and M35501FP, a column discrepancy of display may occur. Prevent the column discrepancy by using the OVF<sub>OUT</sub> output of M35501FP.

The OVF<sub>OUT</sub> pin of M35501FP outputs an overflow signal. The overflow signal is the signal which outputs “H” synchronizing to the last digit output signal of M35501FP, and the signal is output at definite intervals in the correct state. Incorrect state is detected by measuring the output period of this signal, and a column discrepancy is prevented.

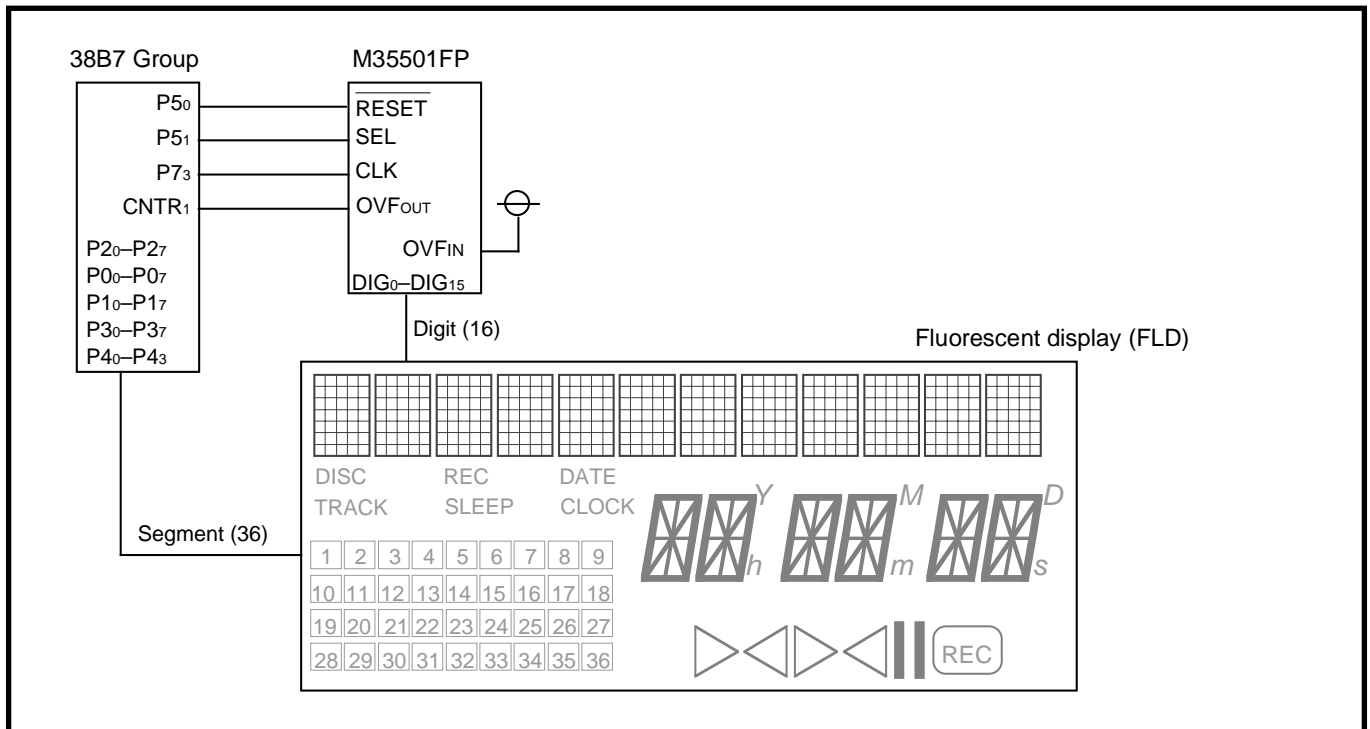

Fig. 2.4.38 Connection diagram

- Specifications:**
- Use of M35501FP (M35501: 16 digits, 38B7 Group: 36 segments)  
Ports P<sub>50</sub> and P<sub>51</sub> of 38B7 Group supply signal to the RESET and SEL pins of M35501FP respectively.  
The P<sub>73</sub> pin (dimmer output pin) supply signals to the CLK pin of M35501FP.
  - Use of FLD automatic display mode of 38B7 Group
  - Display in gradation display mode and 16 timing mode
  - T<sub>off1</sub> = 40 μs, T<sub>off2</sub> = 64 μs, T<sub>disp</sub> = 204 μs, f(X<sub>IN</sub>) = 4 MHz

**Countermeasures against column discrepancy** → •OVF<sub>OUT</sub> output of M35501FP input to CNTR<sub>1</sub> pin of 38B7 Group  
Input signal to CNTR<sub>1</sub> pin is counted as a count source by timer 4 of 38B7 Group  
The timer 6 interrupt is generated each time FLD display period (T<sub>disp</sub> (204 μs) × 16 column = 3.264 ms), and a value of timer 4 is confirmed. M35501FP is reset at incorrect state.

Figure 2.4.39 shows the timing chart (at correct state) of 38B7 Group and M35501FP, and Figure 2.4.40 shows the timing chart (at incorrect state) of 38B7 Group and M35501FP.

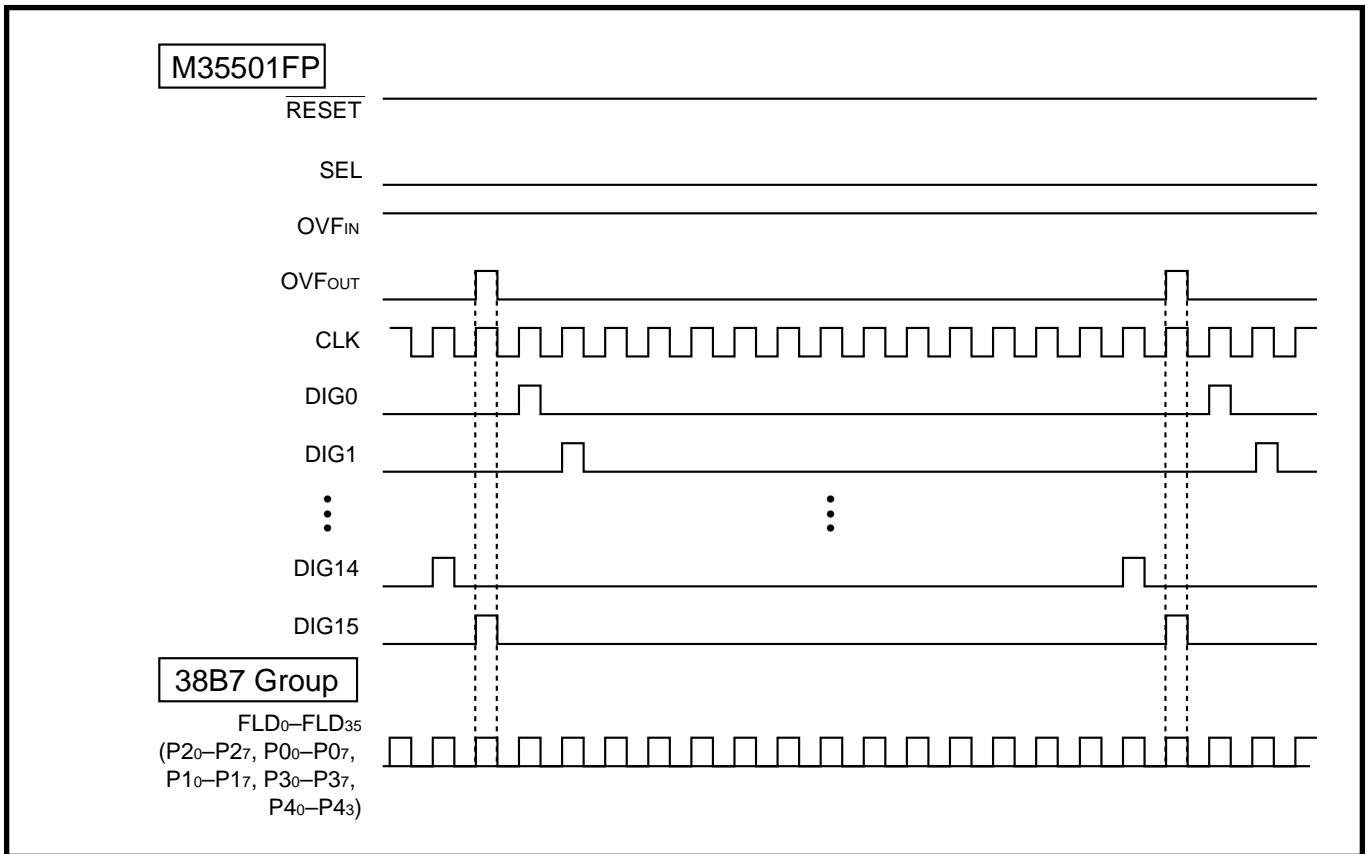

Fig. 2.4.39 Timing chart (at correct state) of 38B7 Group and M35501FP

Fig. 2.4.40 Timing chart (at incorrect state) of 38B7 Group and M35501FP

# APPLICATION

## 2.4 FLD controller

Figure 2.4.41 shows the setting of relevant registers.

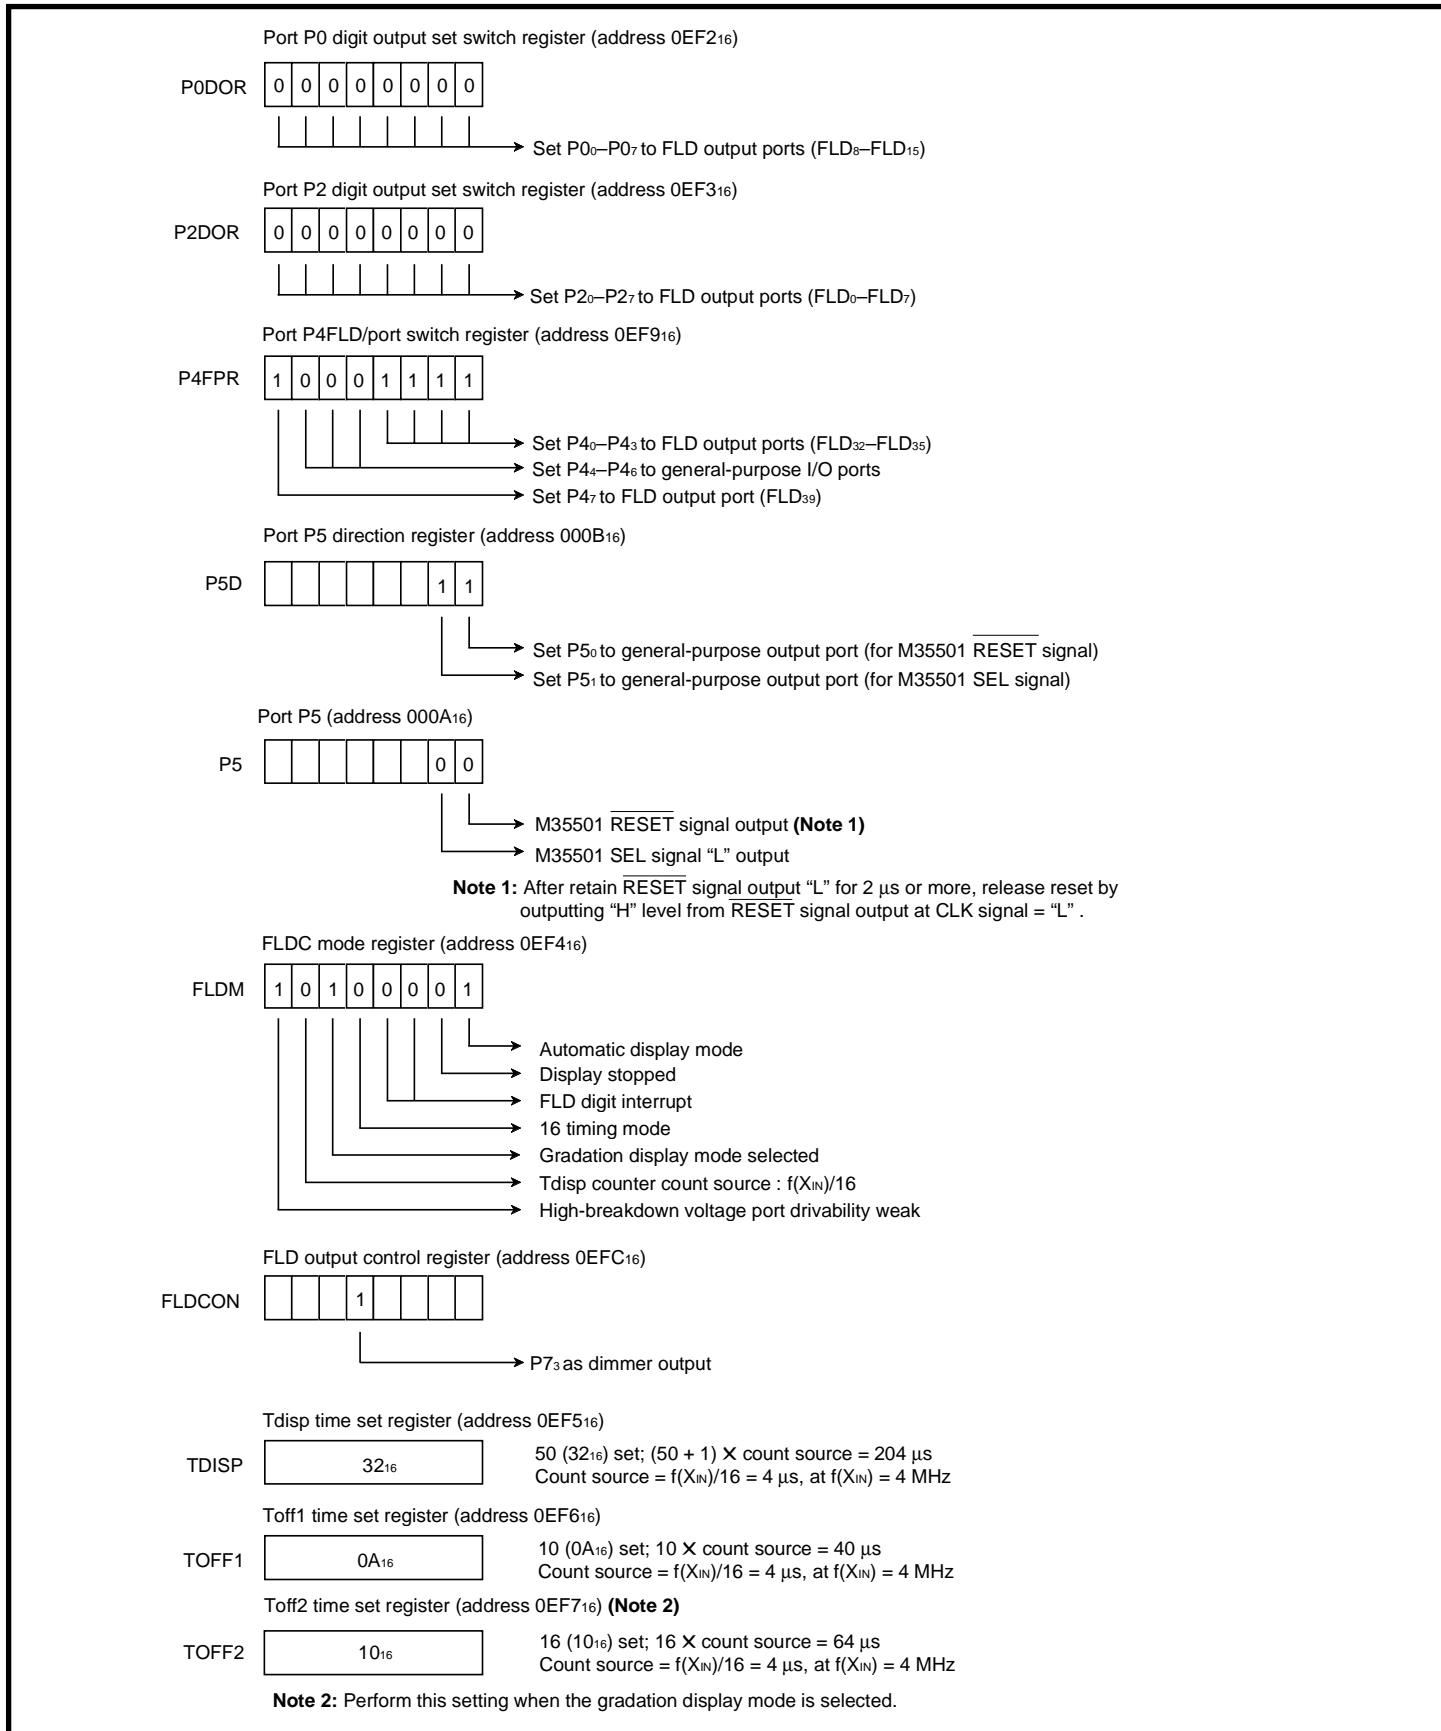

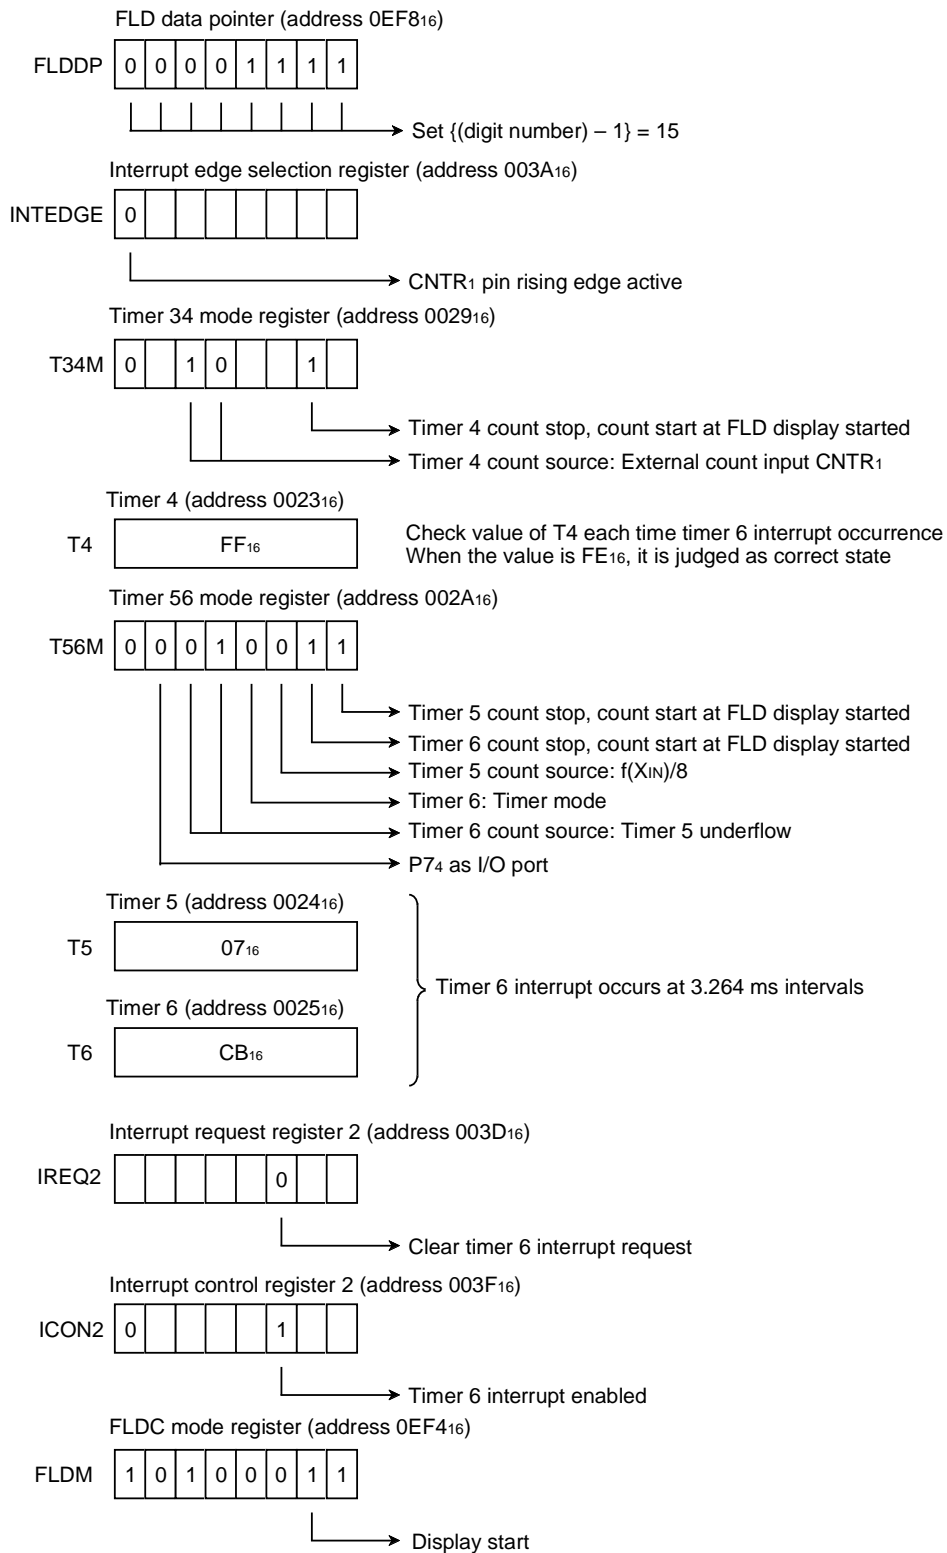

Fig. 2.4.41 Setting of relevant registers

# APPLICATION

## 2.4 FLD controller

### Control procedure:

Figure 2.4.42 shows the control procedure.

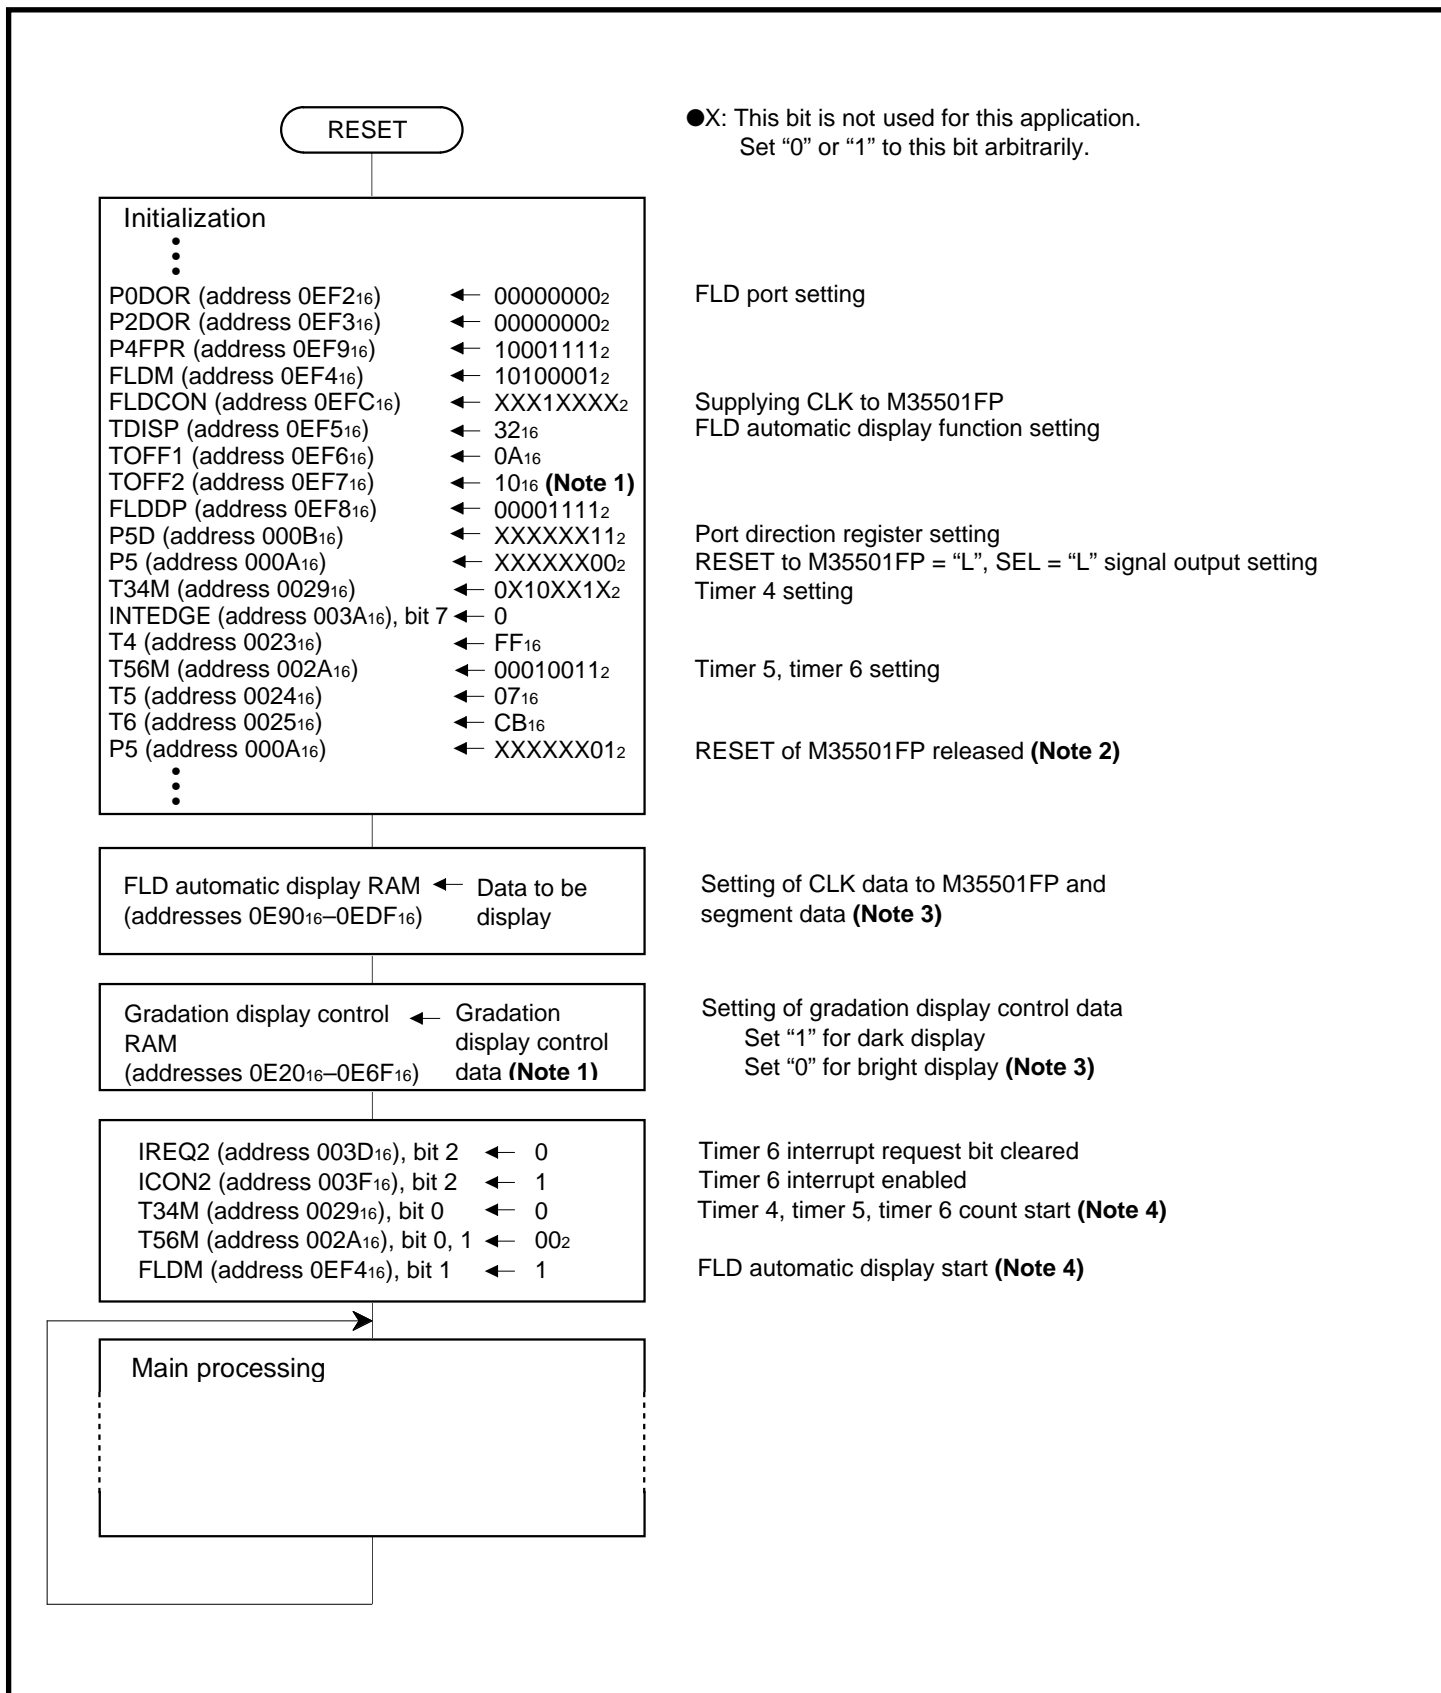

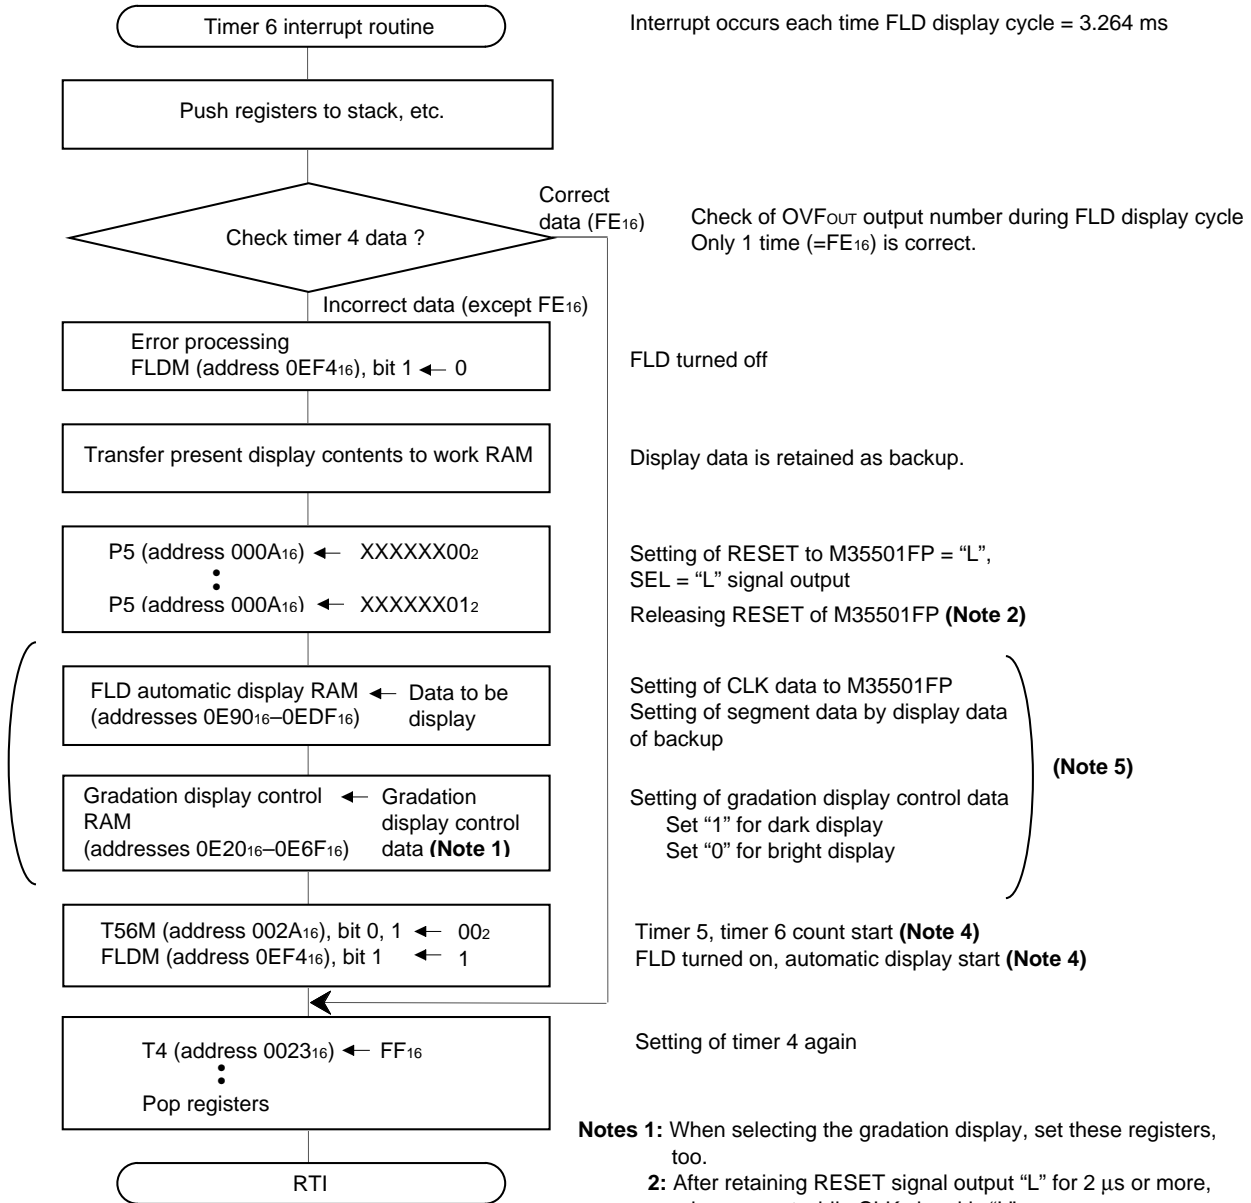

Fig. 2.4.42 Control procedure

**Notes 1:** When selecting the gradation display, set these registers, too.

**2:** After retaining RESET signal output "L" for 2 μs or more, release reset while CLK signal is "L".

**3:** The display data can be rewritten at arbitrary timing.

**4:** Synchronize count start timing of timer 5 and timer 6 with FLD automatic display start timing as possible.

**5:** Set segment data of M35501FP at reset and others according to necessity.

# APPLICATION

## 2.4 FLD controller

---

### 2.4.4 Notes on FLD controller

- Set a value of 03<sub>16</sub> or more to the Toff1 time set register.
- When displaying in the gradation display mode, select the 16 timing mode by the timing number control bit (bit 4 of FLDC mode register (address 0EF4<sub>16</sub>) = "0").

## 2.5 A-D converter

This paragraph describes the setting method of A-D converter relevant registers, notes etc.

## 2.5 A-D converter

### 2.5.3 A-D converter application examples

#### (1) Read-in of analog signal

**Outline:** The analog input voltage input from a sensor is converted to digital values.

Figure 2.5.8 shows a connection diagram, and Figure 2.5.9 shows the setting of relevant registers.

Fig. 2.5.8 Connection diagram

**Specifications:**

- Conversion of analog input voltage input from sensor to digital values
- Use of PA0/AN0 pin as analog input pin

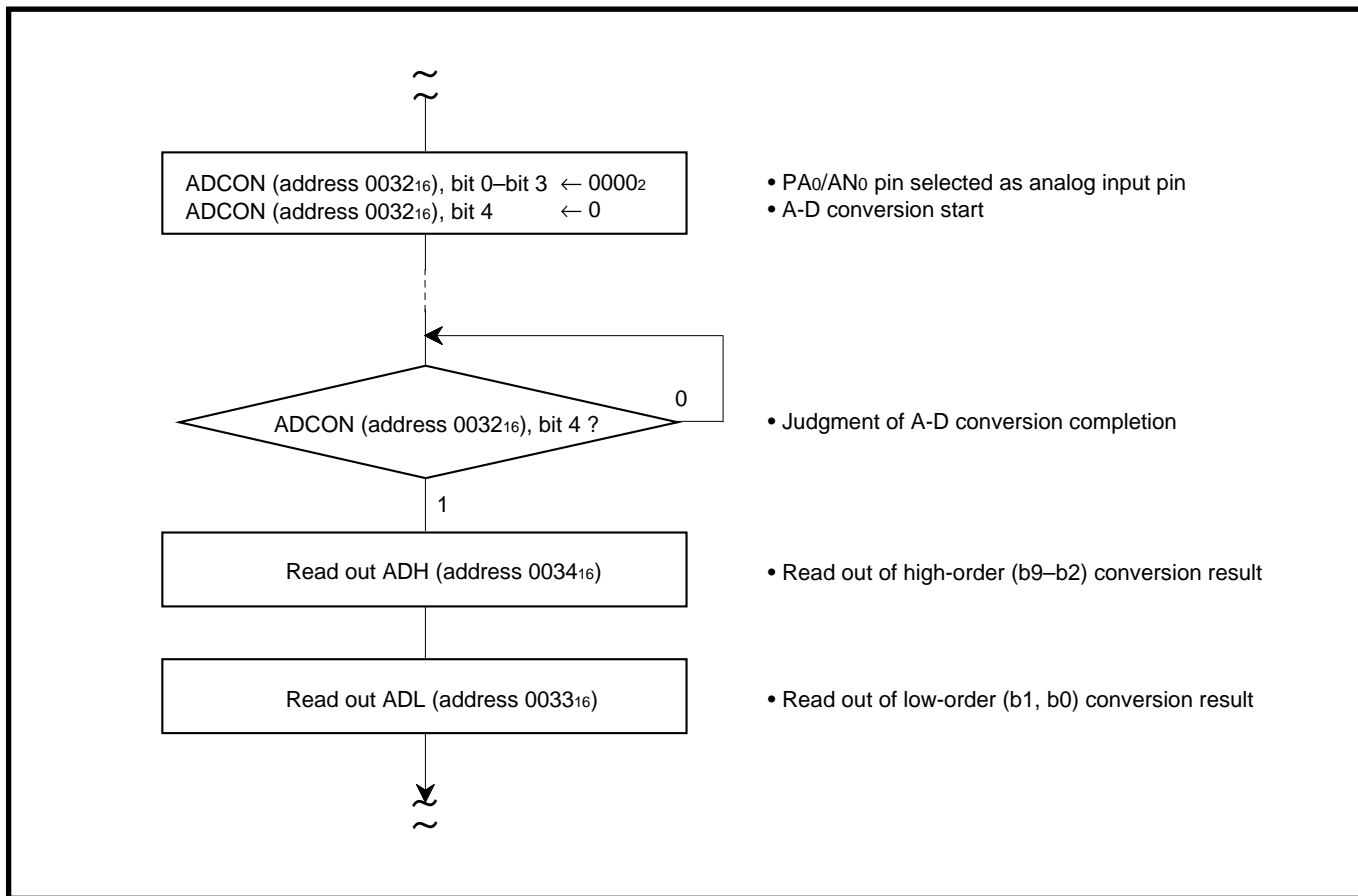

Fig. 2.5.9 Setting of relevant registers

**Control procedure:** A-D converter is started by performing register setting shown Figure 2.5.9. Figure 2.5.10 shows the control procedure.

**Fig. 2.5.10 Control procedure**

# APPLICATION

## 2.5 A-D converter

---

### 2.5.4 Notes on A-D converter

#### (1) Analog input pin

- Make the signal source impedance for analog input low, or equip an analog input pin with an external capacitor of 0.01  $\mu\text{F}$  to 1  $\mu\text{F}$ . Further, be sure to verify the operation of application products on the user side.

#### ● Reason

An analog input pin includes the capacitor for analog voltage comparison. Accordingly, when signals from signal source with high impedance are input to an analog input pin, charge and discharge noise generates. This may cause the A-D conversion precision to be worse.

#### (2) A-D converter power source pin

The AVss pin is A-D converter power source pin. Regardless of using the A-D conversion function or not, connect it as following :

- AVss : Connect to the Vss line

#### ● Reason

If the AVss pin is opened, the microcomputer may have a failure because of noise or others.

#### (3) Clock frequency during A-D conversion

The comparator consists of a capacity coupling, and a charge of the capacity will be lost if the clock frequency is too low. Thus, make sure the following during an A-D conversion.

- $f(\text{XIN})$  is 250 kHz or more
- Do not execute the **STP** instruction and **WIT** instruction

### 2.6 D-A converter

This paragraph describes the setting method of D-A converter relevant registers, notes etc.

#### 2.6.1 Memory assignment

Fig. 2.6.1 Memory assignment of D-A converter relevant registers

#### 2.6.2 Relevant registers

# APPLICATION

## 2.6 D-A converter

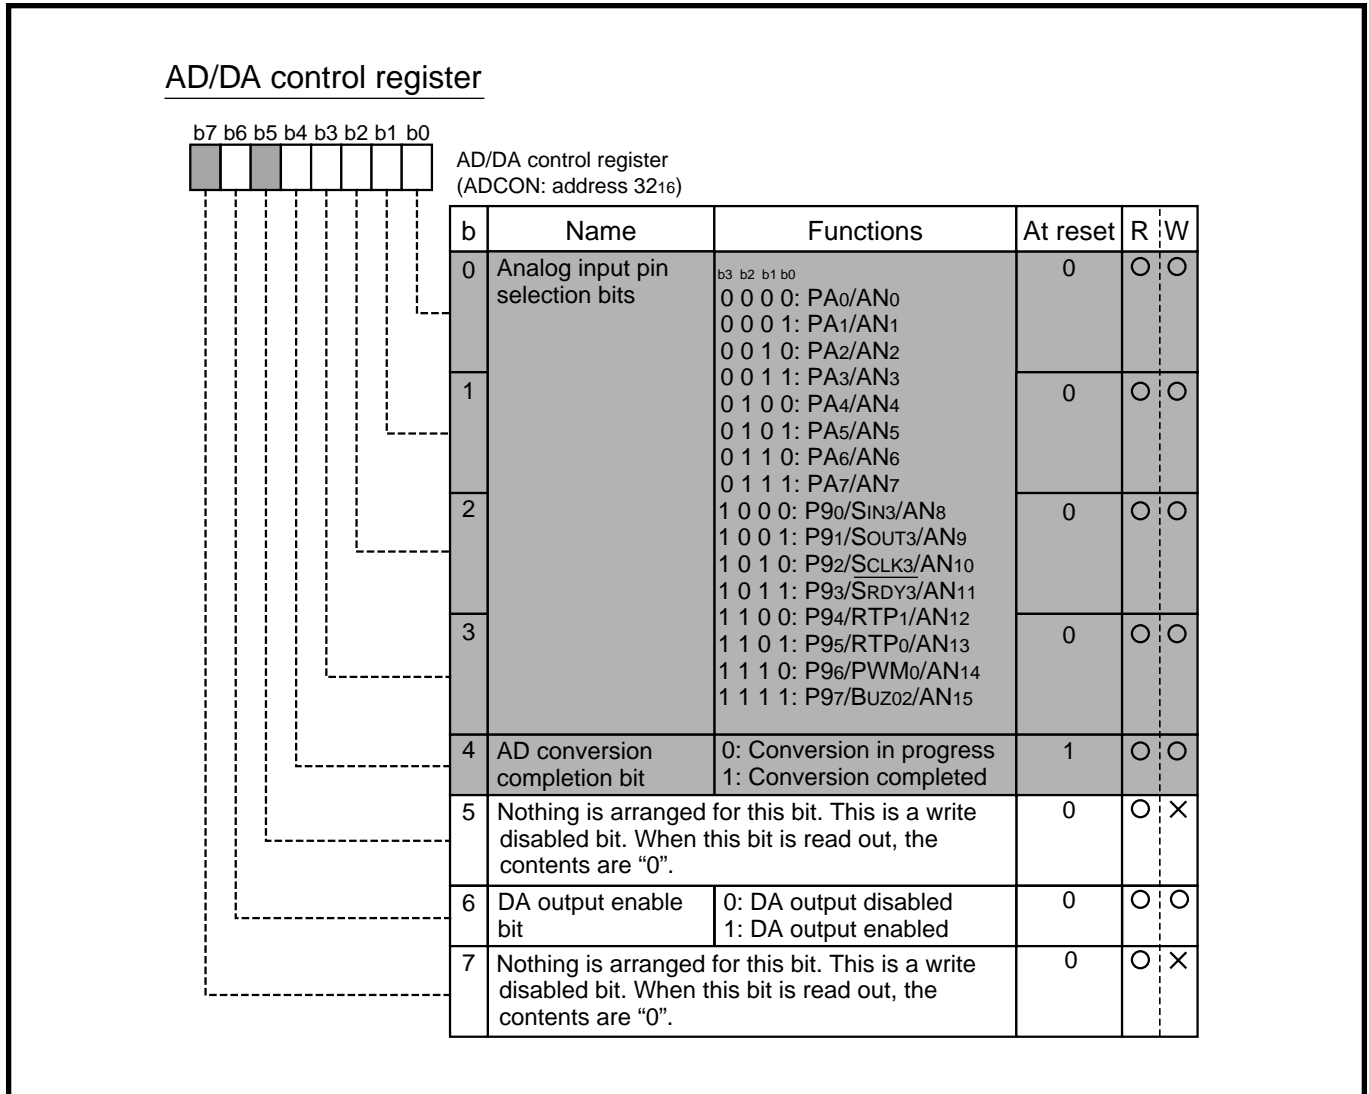

Fig. 2.6.3 Structure of AD/DA control register

### 2.6.3 D-A converter application examples

**Outline:** Digital value is converted to the analog output voltage.

Figure 2.6.4 shows a connection diagram, and Figure 2.6.5 shows the setting of relevant registers.

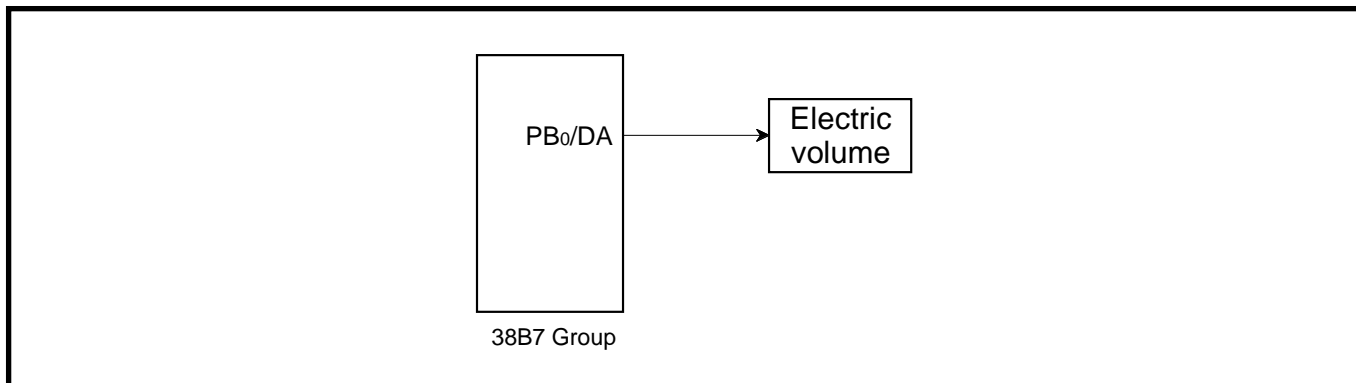

Fig. 2.6.4 Connection diagram

**Specifications:** •Conversion of digital value to analog output voltage.

Fig. 2.6.5 Setting of relevant registers

# APPLICATION

## 2.6 D-A converter

**Control procedure:** D-A converter is started by performing register setting shown Figure 2.6.5. Figure 2.6.6 shows the control procedure.

Fig. 2.6.6 Control procedure

### 2.6.4 Notes on D-A converter

#### (1) PB<sub>0</sub>/DA pin state at reset

The PB<sub>0</sub>/DA pin becomes a high-impedance state at reset.

#### (2) Connection with low-impedance load

If connecting a D-A output with a load having a low impedance, use an external buffer. It is because the D-A converter circuit does not include a buffer.

#### (3) Usable voltage

V<sub>cc</sub> must be 3.0 V or more when using the D-A converter.

### 2.7 PWM

This paragraph describes the setting method of PWM relevant registers, notes etc.

#### 2.7.1 Memory assignment

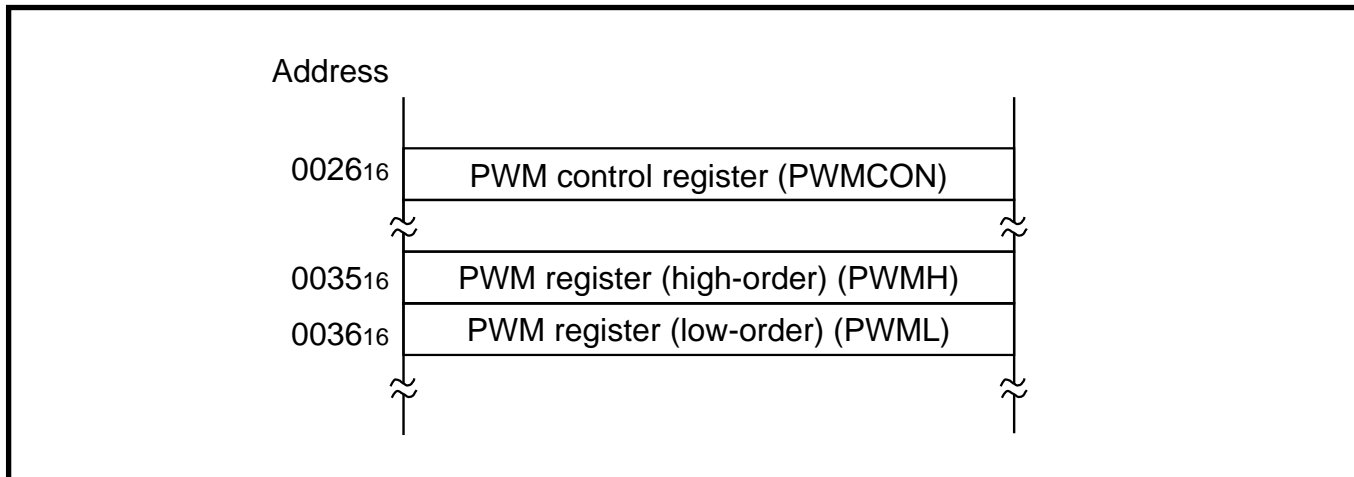

Fig. 2.7.1 Memory assignment of PWM relevant registers

## (1) Control of VS tuner

Figure 2.7.5 shows a connection diagram, and Figure 2.7.6 shows the setting of relevant registers.

Fig. 2.7.5 Connection diagram

- Outline:**
- Control of VS tuner by using the 14-bit resolution PWM<sub>0</sub> output function
  - $f(X_{IN}) = 4 \text{ MHz}$

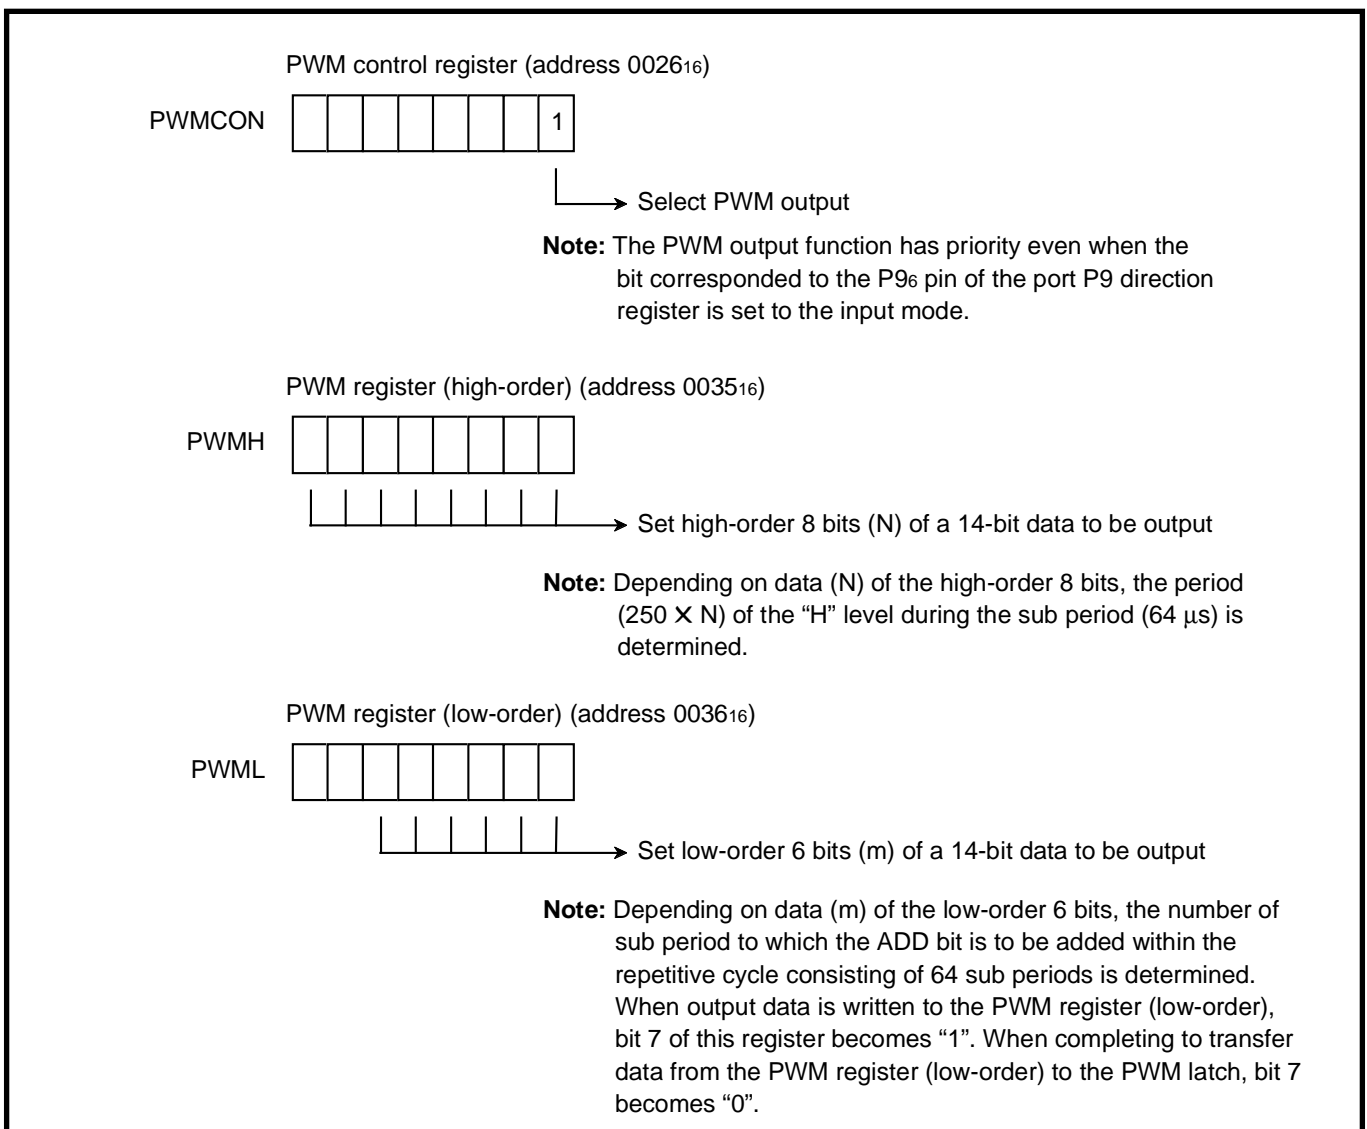

Fig. 2.7.6 Setting of relevant registers

# APPLICATION

## 2.7 PWM

**Control procedure:** PWM waveform is output to the external by setting relevant registers shown in Figure 2.7.6. This PWM<sub>0</sub> output is integrated through the low pass filter and converted into DC signals for control of the VS tuner. Figure 2.7.7 shows the control procedure.

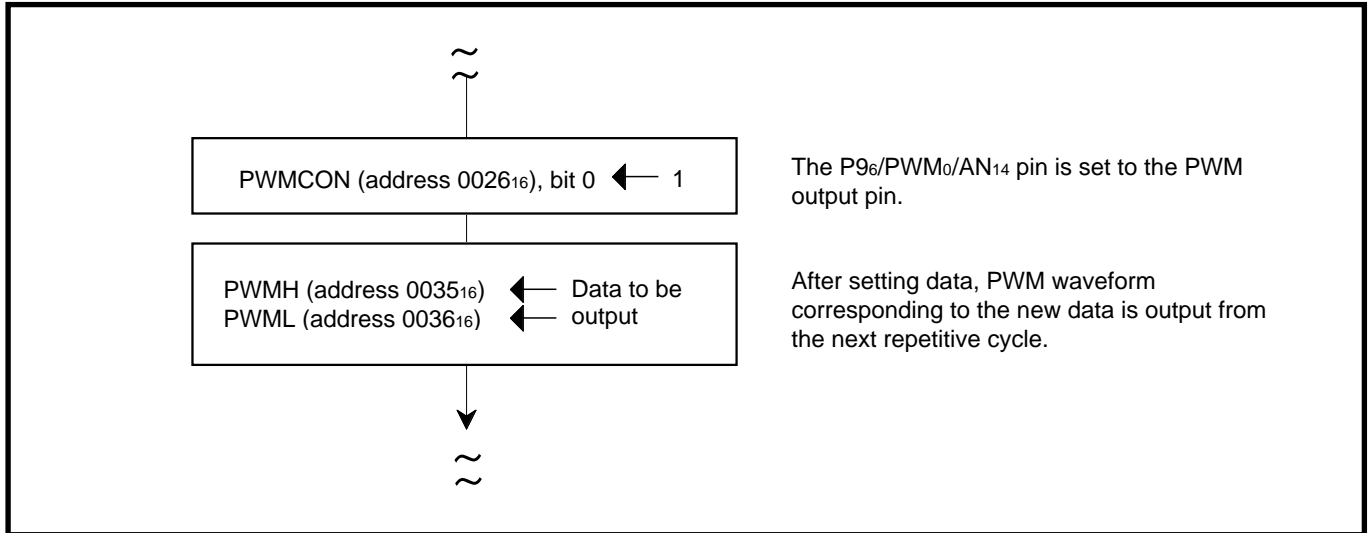

Fig. 2.7.7 Control procedure

### 2.7.4 Notes on PWM

- For PWM<sub>0</sub> output, “L” level is output first.
- After data is set to the PWM register (low-order) and the PWM register (high-order), PWM waveform corresponding to new data is output from next repetitive cycle.

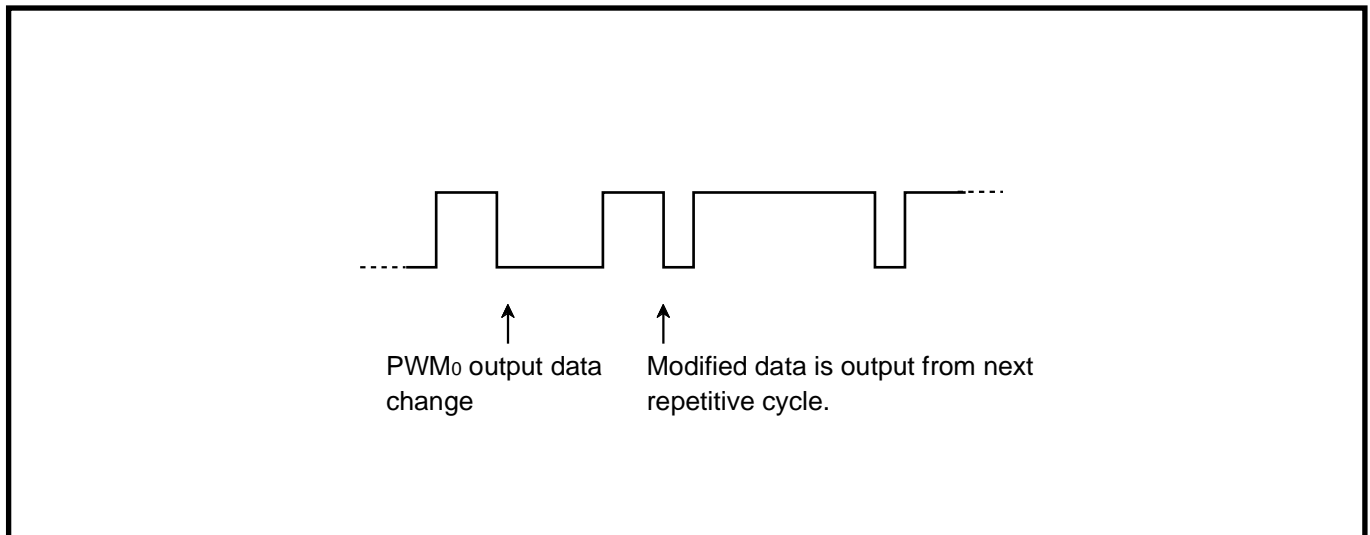

Fig. 2.7.8 PWM<sub>0</sub> output

## 2.8 Interrupt interval determination function

### 2.8 Interrupt interval determination function

This paragraph describes the setting method of interrupt interval determination function relevant registers, notes etc.

### 2.9 Watchdog timer

This paragraph describes the setting method of watchdog timer relevant register, notes etc.

#### 2.9.1 Memory assignment

Fig. 2.9.1 Memory assignment of watchdog timer relevant register

#### 2.9.2 Relevant register

Fig. 2.9.2 Structure of Watchdog timer control register

# APPLICATION

## 2.9 Watchdog timer

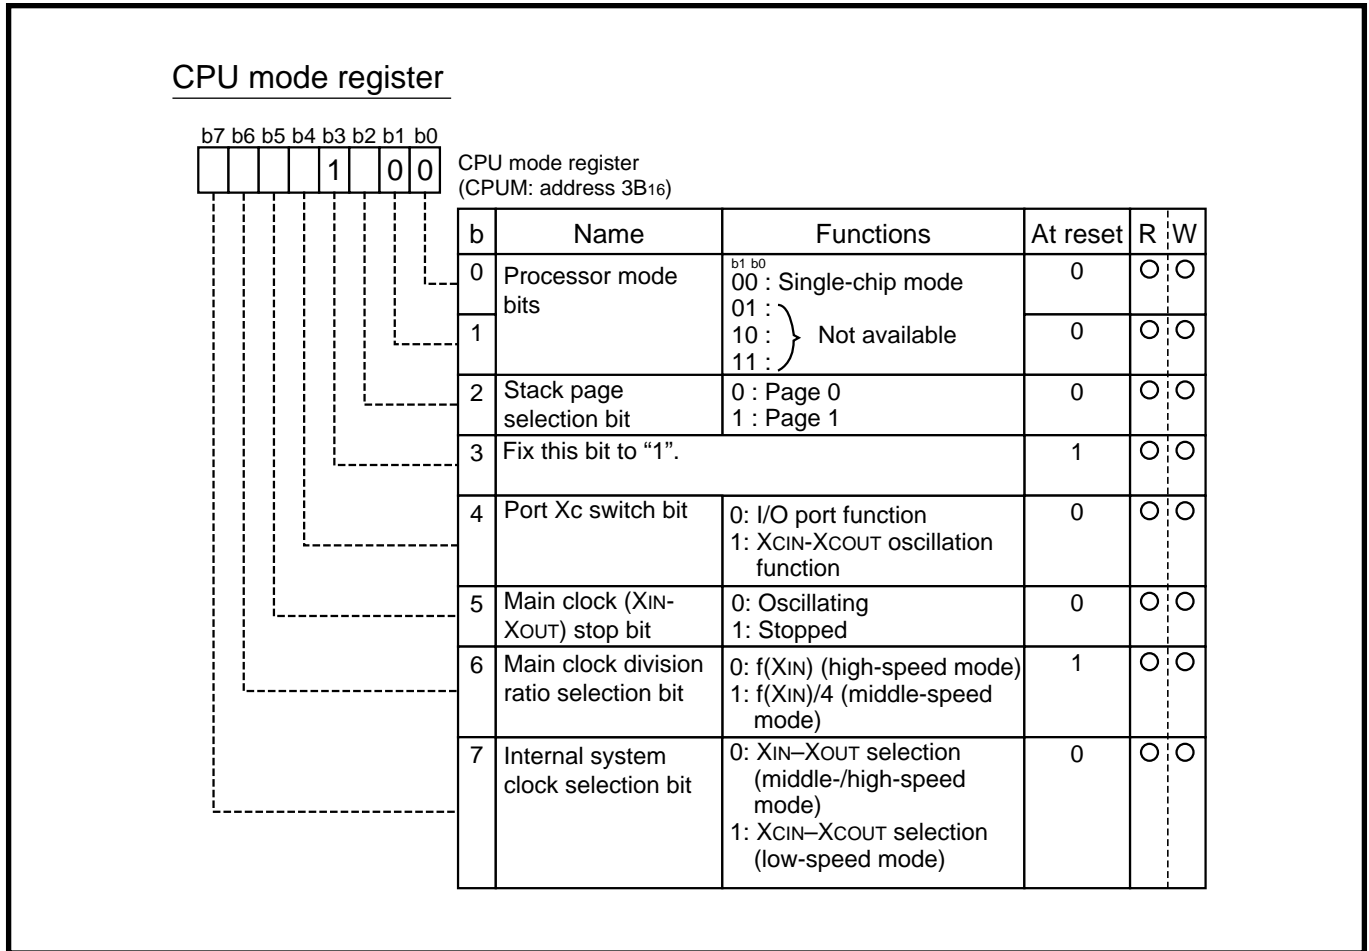

Fig. 2.9.3 Structure of CPU mode register

### 2.9.3 Watchdog timer application examples

**Outline:** When a program runs away, the watchdog timer makes the microcomputer return to the reset state.

**Specifications:** •When the watchdog timer H underflows, it is judged as incorrect program, and the microcomputer is returned to the reset state.

- Bit 7 of the watchdog timer control register is set to “0” at each cycle of the main routine before underflow of the watchdog timer H. (Initialization of watchdog timer value)

- Use of watchdog timer L underflow as count source of watchdog timer H

- Setting of main clock division ratio to  $f(X_{IN})$  (high-speed mode)

Figure 2.9.4 shows the connection of watchdog timer and the setting of the division ratio.

Figure 2.9.5 shows the setting of relevant registers and Figure 2.9.6 shows the control procedure.

Fig. 2.9.4 Connection of watchdog timer and setting of division ratio

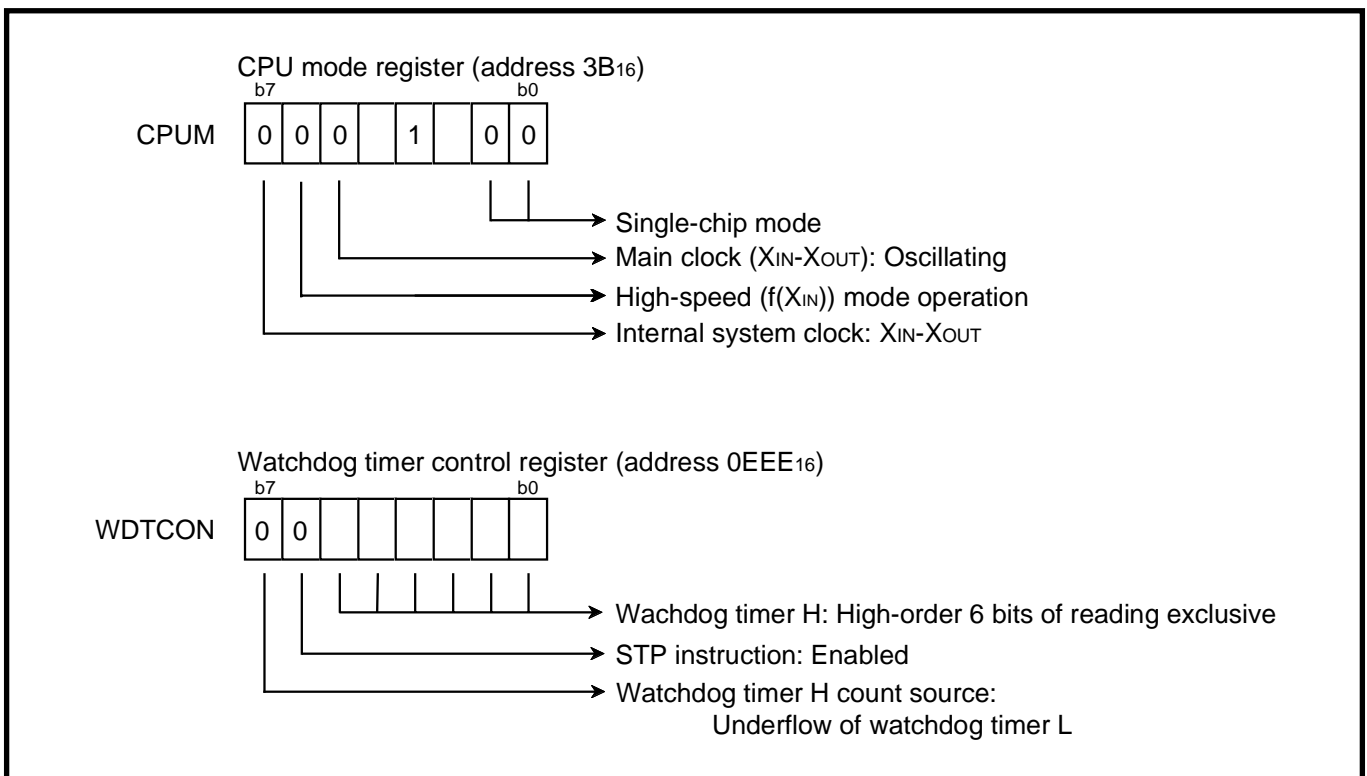

Fig. 2.9.5 Setting of relevant registers

# APPLICATION

## 2.9 Watchdog timer

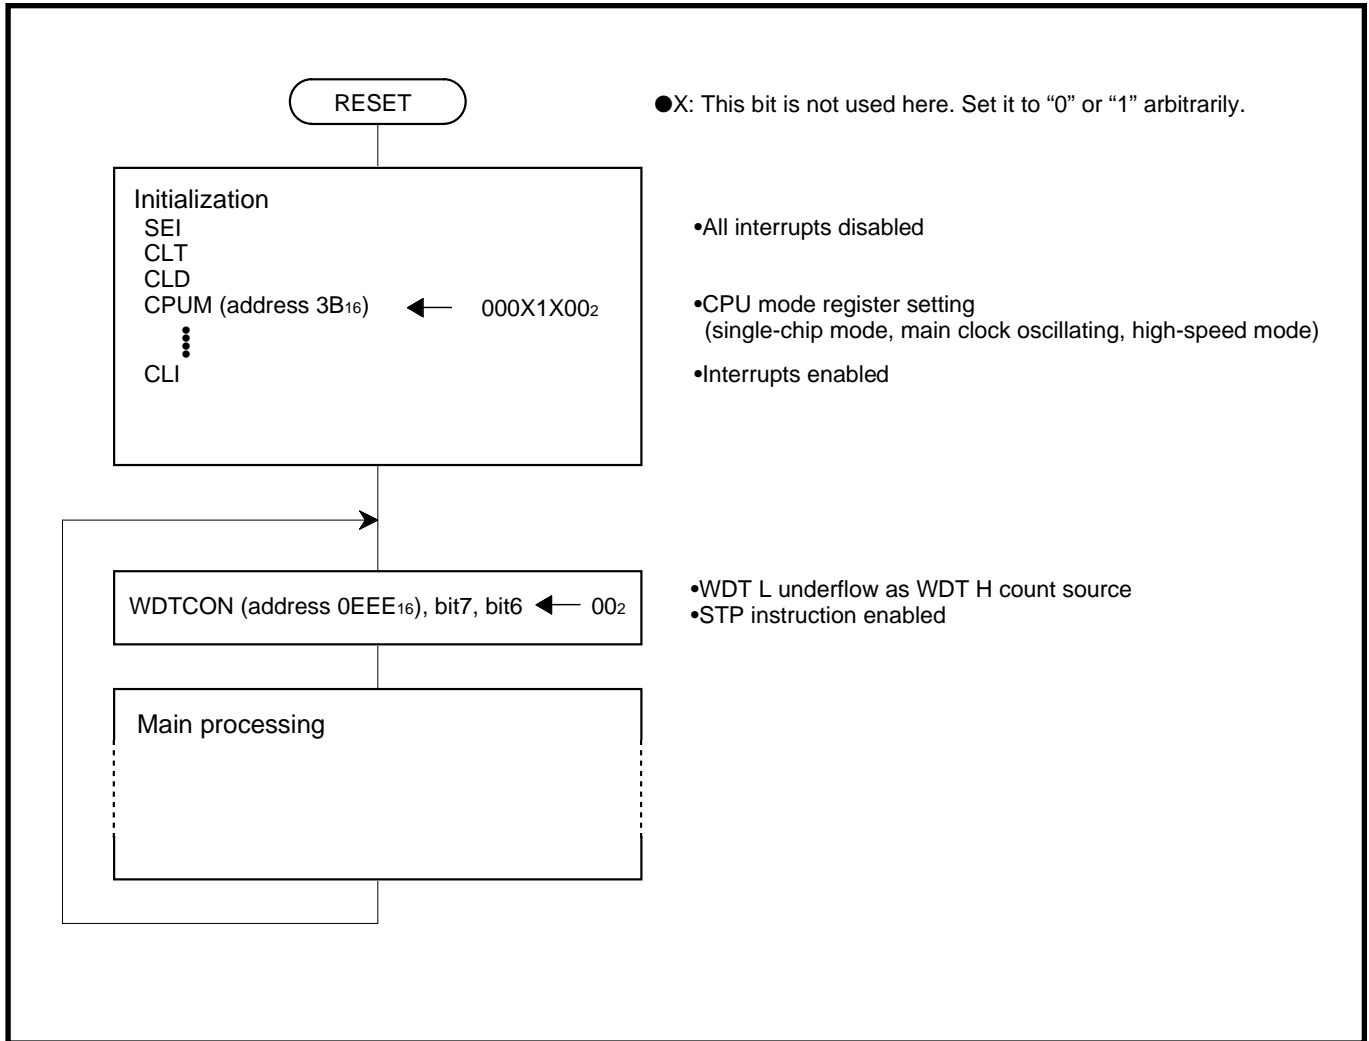

Fig. 2.9.6 Control procedure

### 2.9.4 Notes on watchdog timer

- The watchdog timer continues to count even while waiting for stop release. Accordingly, make sure that watchdog timer does not underflow during this term by writing to the watchdog timer control register (address 0EEE<sub>16</sub>) once before executing the STP instruction, etc.
- Once a "1" is written to the STP instruction disable bit (bit 6) of the watchdog timer control register (address 0EEE<sub>16</sub>), it cannot be programmed to "0" again. This bit becomes "0" after reset.

### 2.10 Buzzer output circuit

The output frequency can be selected from 1 kHz, 2 kHz, or 4 kHz (at  $f(X_{IN}) = 4.19$  MHz), and the output port can be selected between either the BUZ01 pin or the BUZ02 pin.

This paragraph describes the setting method of buzzer output circuit relevant register, notes etc.

#### 2.10.1 Memory assignment

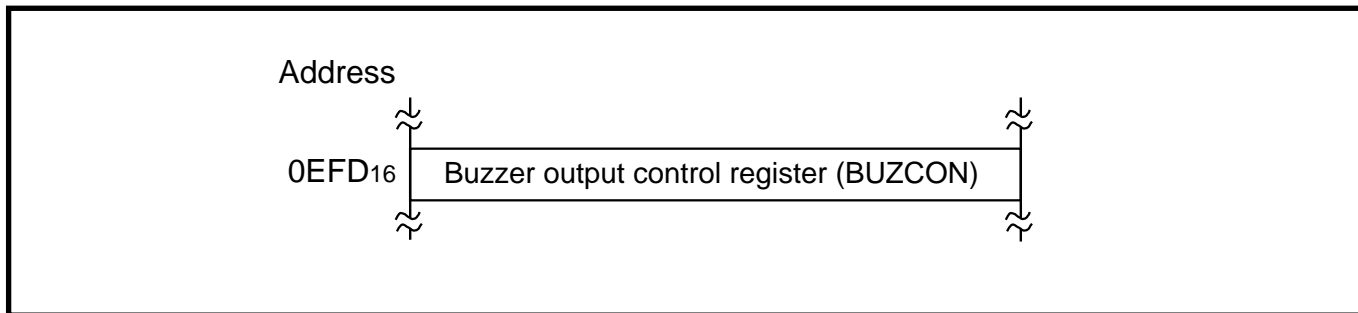

Fig. 2.10.1 Memory assignment of buzzer output circuit relevant register

#### 2.10.2 Relevant register

The buzzer output circuit starts outputting a buzzer by setting the buzzer output ON/OFF bit (bit 4) of the buzzer output control register.

Figure 2.10.2 shows the structure of the buzzer output control register.

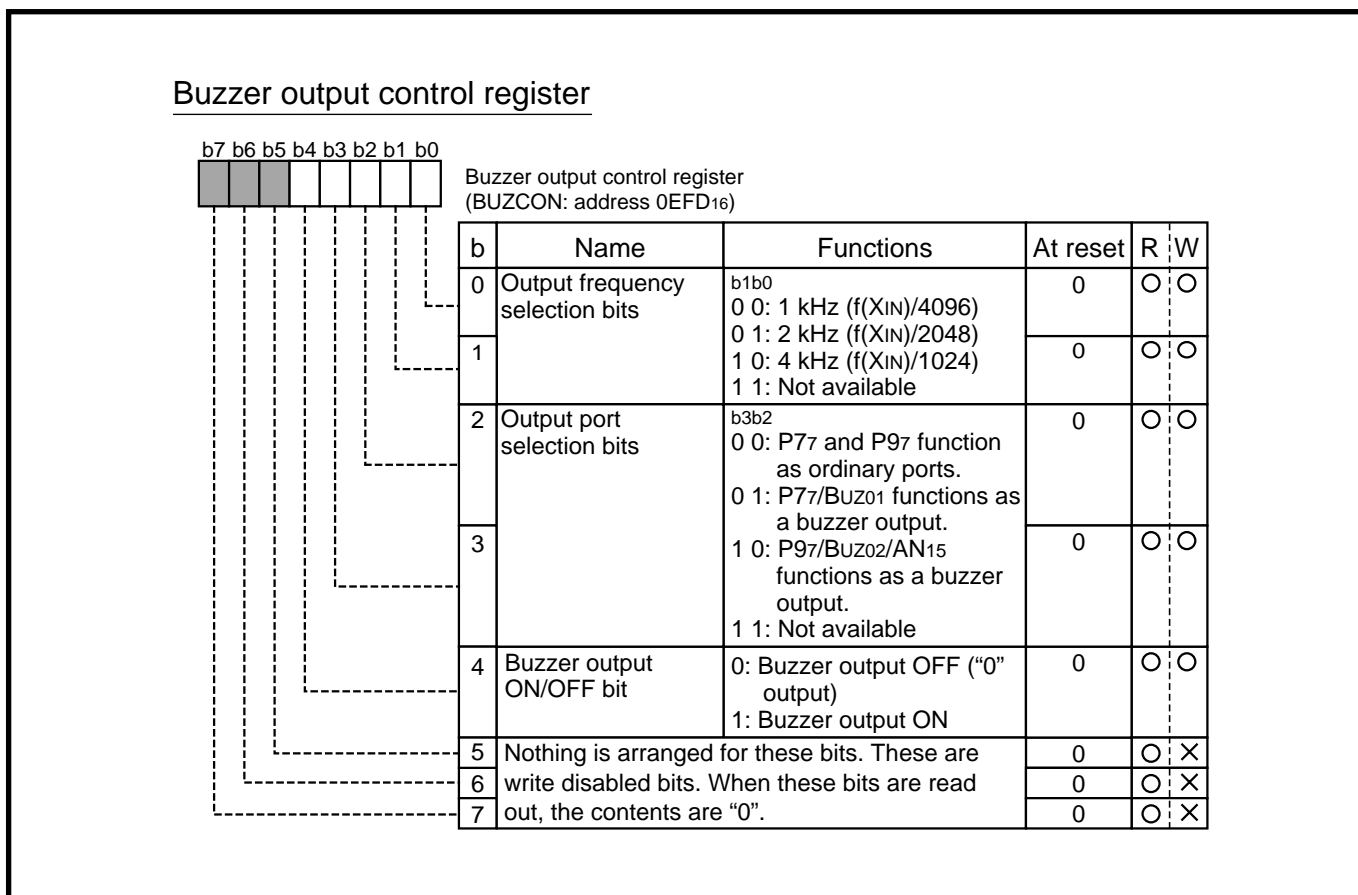

Fig. 2.10.2 Structure of buzzer output control register

# APPLICATION

## 2.10 Buzzer output circuit

### 2.10.3 Buzzer output circuit application examples

**Outline:** A buzzer output is performed by using the buzzer output circuit.

- Specifications:**
- $f(X_{IN}) = 4.19 \text{ MHz}$ , buzzer output frequency = 4 kHz
  - Buzzer output from BUZ01 pin

Figure 2.10.3 shows the connection of buzzer output circuit and the setting of the division ratio. Figure 2.10.4 shows the setting of relevant register. Figure 2.10.5 shows the control procedure.

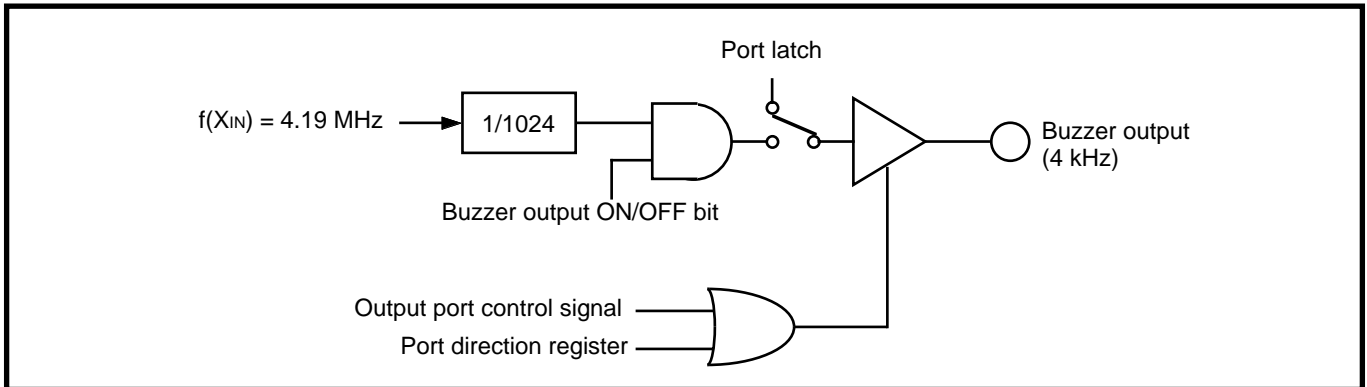

Fig. 2.10.3 Connection of buzzer output circuit and setting of division ratio

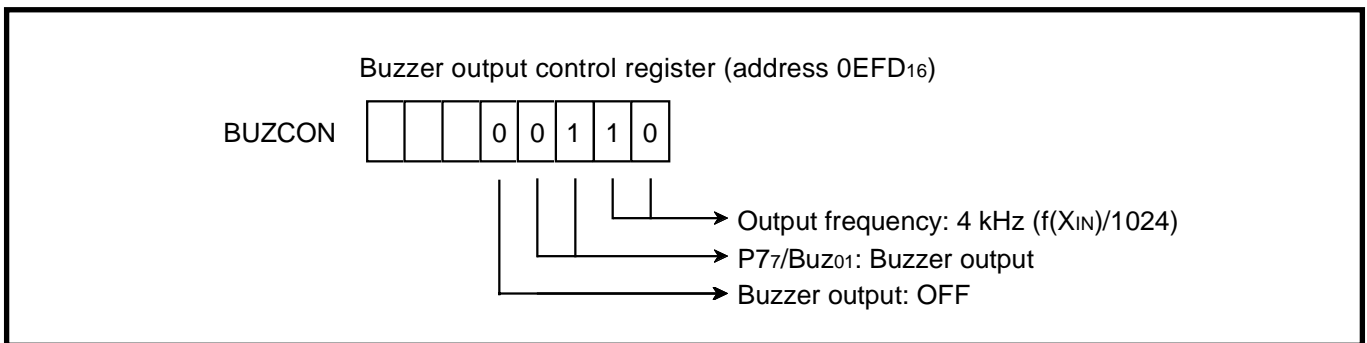

Fig. 2.10.4 Setting of relevant register

Fig. 2.10.5 Control procedure

### 2.11 Reset circuit

The reset state is caused by applying an “L” level to the  $\overline{\text{RESET}}$  pin. After that, the reset state is released by applying an “H” level to the  $\overline{\text{RESET}}$  pin, so that the program is executed in the middle-speed mode from the contents of the reset vector address.

#### 2.11.1 Connection example of reset IC

Figure 2.11.1 shows the example of power-on reset circuit. Figure 2.11.2 shows the system example which switches to the RAM backup mode by detecting a drop of the system power source voltage with the INT interrupt.

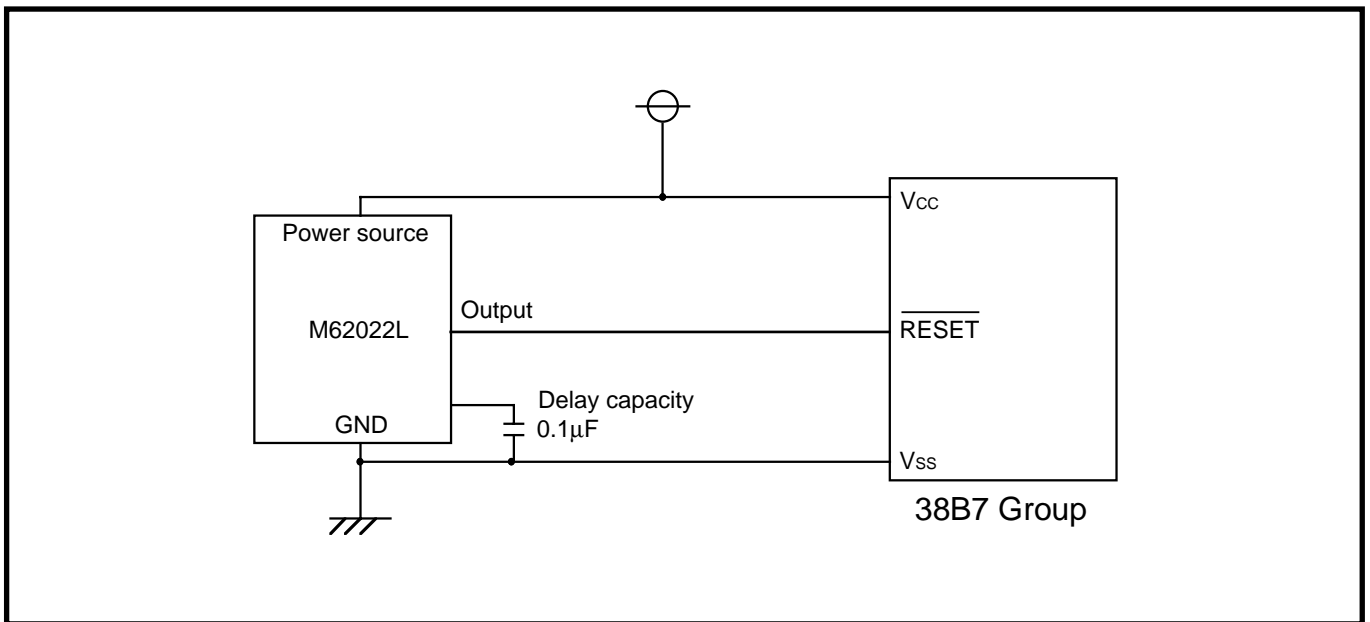

Fig. 2.11.1 Example of power-on reset circuit

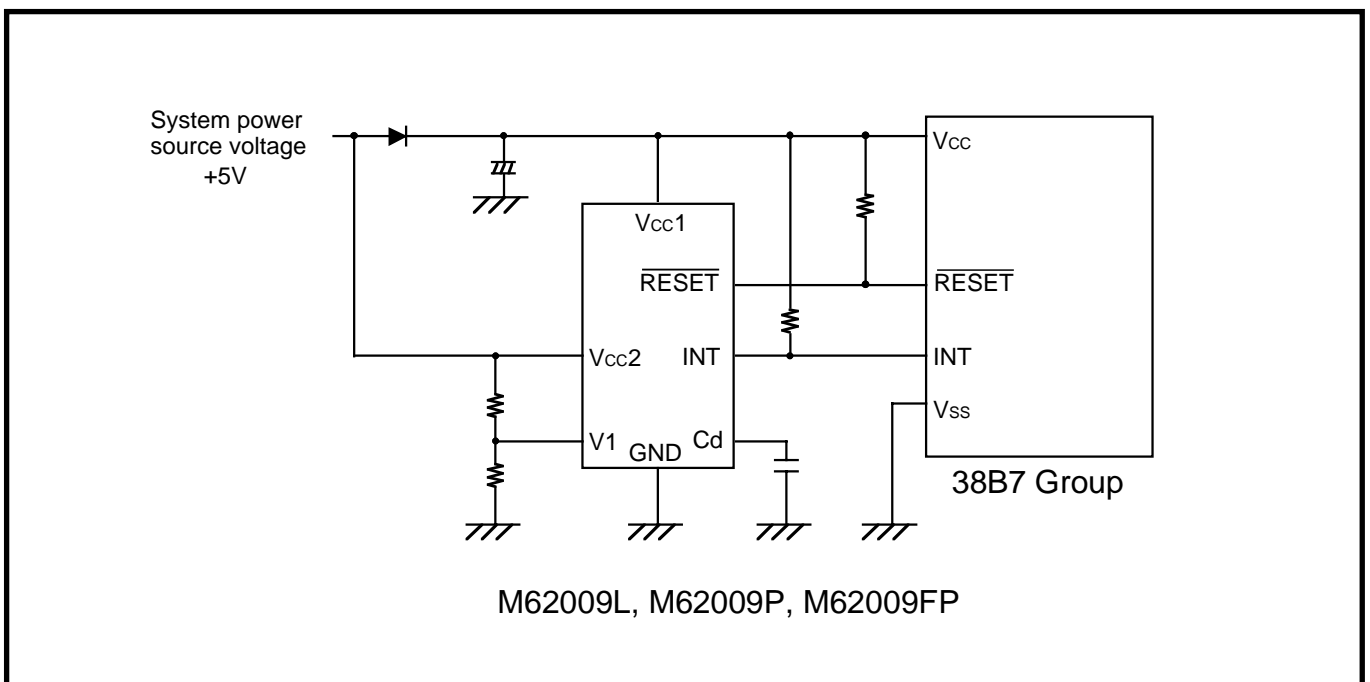

Fig. 2.11.2 RAM backup system example

# APPLICATION

## 2.11 Reset circuit

---

### 2.11.2 Notes on reset

#### (1) Reset input voltage control

Make sure that the reset input voltage is 0.54 V or less for Vcc of 2.7 V.

Perform switch to the high-speed mode when power source voltage is within 4.0 to 5.5 V.

#### (2) Countermeasure when $\overline{\text{RESET}}$ signal rise time is long

In case where the  $\overline{\text{RESET}}$  signal rise time is long, connect a ceramic capacitor or others across the  $\overline{\text{RESET}}$  pin and the Vss pin. And use a 1000 pF or more capacitor for high frequency use. When connecting the capacitor, note the following :

- Make the length of the wiring which is connected to a capacitor as short as possible.
- Be sure to verify the operation of application products on the user side.

#### ● Reason

If the several nanosecond or several ten nanosecond impulse noise enters the  $\overline{\text{RESET}}$  pin, it may cause a microcomputer failure.

### 2.11.3 Each port state during “L” state of $\overline{\text{RESET}}$ pin

Table 2.11.1 shows a pin state during “L” state of  $\overline{\text{RESET}}$  pin.

Table 2.11.1 Pin state during “L” state of  $\overline{\text{RESET}}$  pin

Pin name	Pin state
P0, P2	Output port (with pull-down resistor)
P1, P3	Input port (with pull-down resistor)
P4, P5, P6 <sub>0</sub> to P6 <sub>3</sub>	Input port (without pull-down resistor)
P6 <sub>4</sub> to P6 <sub>7</sub> , P7, P8 <sub>0</sub> to P8 <sub>3</sub> , P9, PA, PB <sub>0</sub> to PB <sub>6</sub>	Input port (floating)

### 2.12 Clock generating circuit

This paragraph explains the setting method of clock generating circuit relevant register, etc.

#### 2.12.1 Relevant register

Figure 2.12.1 shows the structure of the CPU mode register.

Fig. 2.12.1 Structure of CPU mode register

# APPLICATION

## 2.12 Clock generating circuit

### 2.12.2 Clock generating circuit application examples

#### (1) Status transition during power failure

**Outline:** The clock is counted up every one second by using the timer interrupt during a power failure.

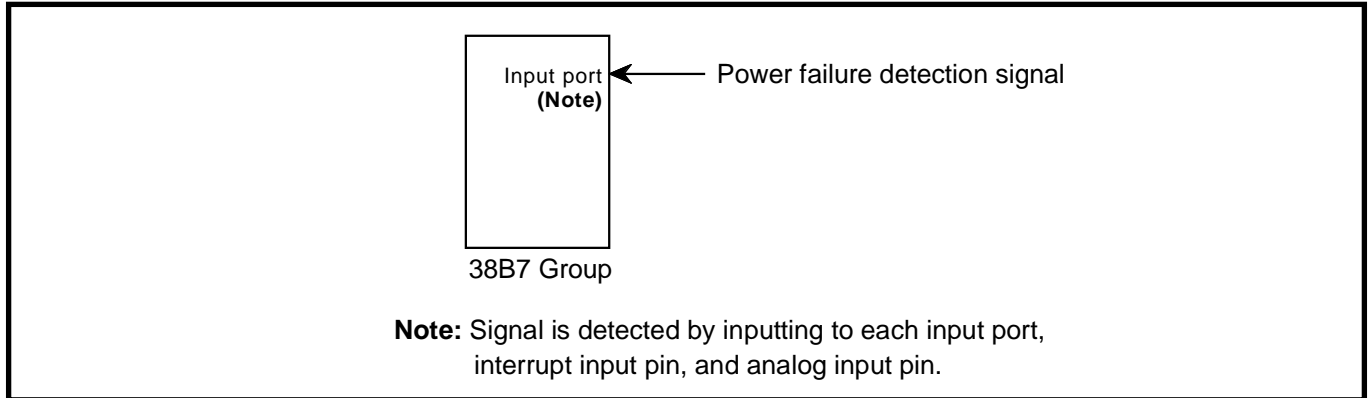

Fig. 2.12.2 Connection diagram

- Specifications:**
- Reducing power dissipation as low as possible while maintaining clock function
  - Clock:  $f(X_{IN}) = 4.19 \text{ MHz}$ ,  $f(X_{CIN}) = 32.768 \text{ kHz}$
  - Port processing
    - Input port: Fixed to “H” or “L” level on the external
    - Output port: Fixed to output level that does not cause current flow to the external  
(Example) When a circuit turns on LED at “L” output level, fix the output level to “H”.
    - I/O port: Input port → Fixed to “H” or “L” level on the external  
Output port → Output of data that does not consume current
    - $V_{REF}$ : Stop to supply to reference voltage input pin by external circuit

Figure 2.12.3 shows the status transition diagram during power failure and Figure 2.12.4 shows the setting of relevant registers.

Fig. 2.12.3 Status transition diagram during power failure

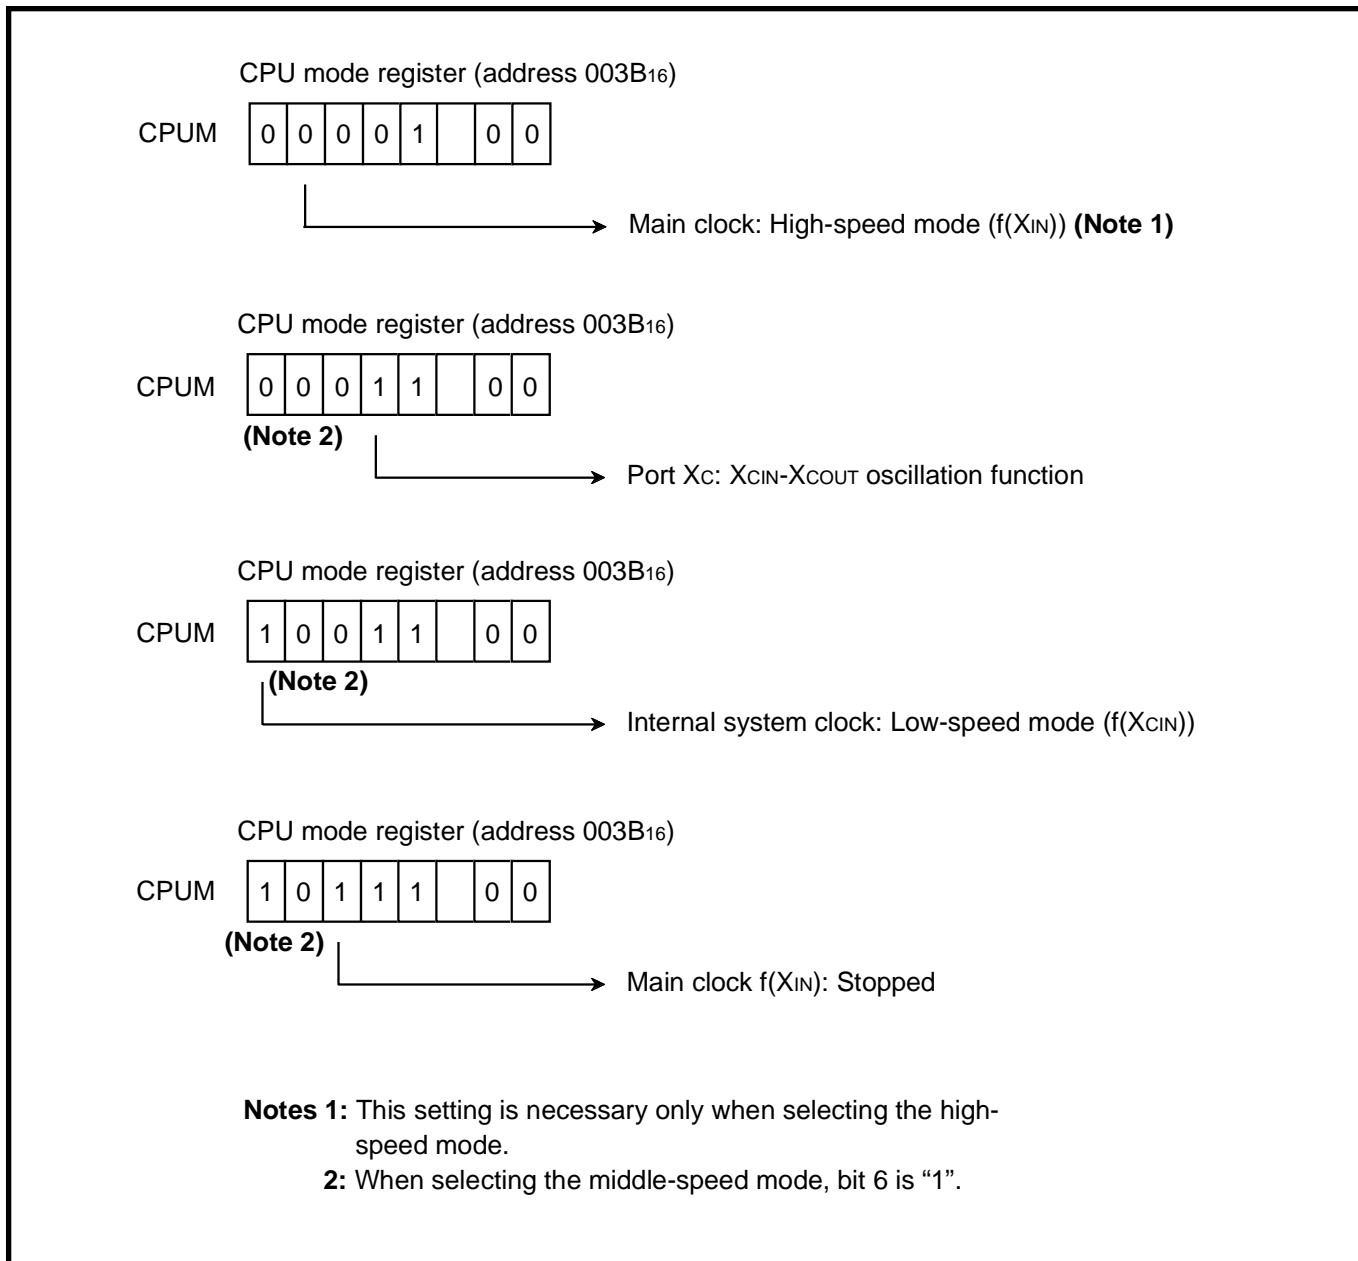

Fig. 2.12.4 Setting of relevant registers

# APPLICATION

## 2.12 Clock generating circuit

**Control procedure:** Set the relevant registers in the order shown below to prepare for a power failure.

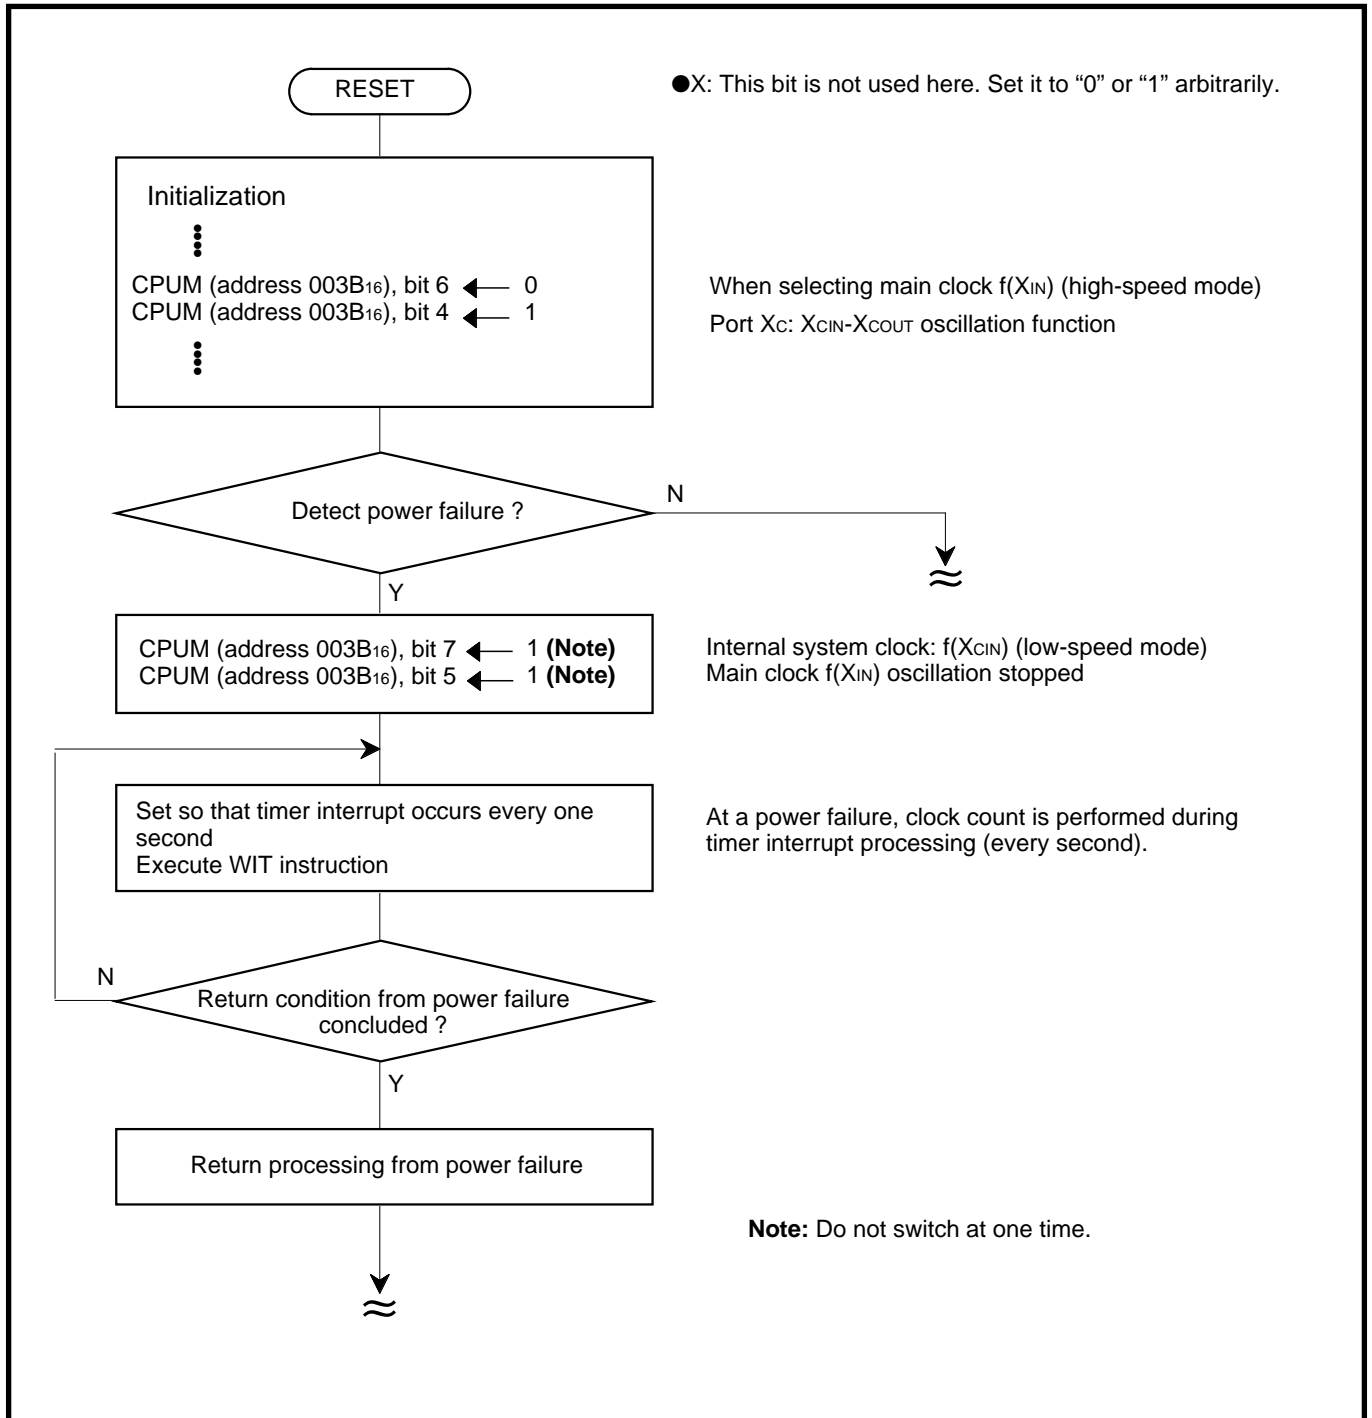

Fig. 2.12.5 Control procedure

### (2) Counting without clock error during power failure

**Outline:** It keeps counting without clock error during a power failure.

**Specifications:**

- Reducing power consumption as low as possible while maintaining clock function

- Clock:  $f(X_{IN}) = 4.19 \text{ MHz}$

- Sub clock:  $f(X_{CIN}) = 32.768 \text{ kHz}$

- Use of Timer 3 interrupt

For the peripheral circuit and the status transition during a power failure, refer to Figures 2.12.2 and 2.12.3.

Figure 2.12.6 shows the structure of clock counter, Figures 2.12.7 and 2.12.8 show the setting of relevant registers.

## 2.13 Flash memory

### 2.13 Flash memory

This paragraph explains the registers setting method and the notes relevant to the flash memory version.

#### 2.13.1 Overview

The flash memory version has functions similar to those of the mask ROM version except that the flash memory is built-in. However, some of SFR area of flash memory version is different from those of the mask ROM version (refer to “2.13.2 Memory map”).

In the flash memory version, the built-in flash memory can be operated by using the following three modes.

- CPU reprogramming mode
- Parallel input/output mode
- Serial input/output mode

#### 2.13.2 Memory map

M38B79FFFP has the built-in flash memory of 60 Kbytes.

Figure 2.13.1 shows the memory map of the flash memory version.

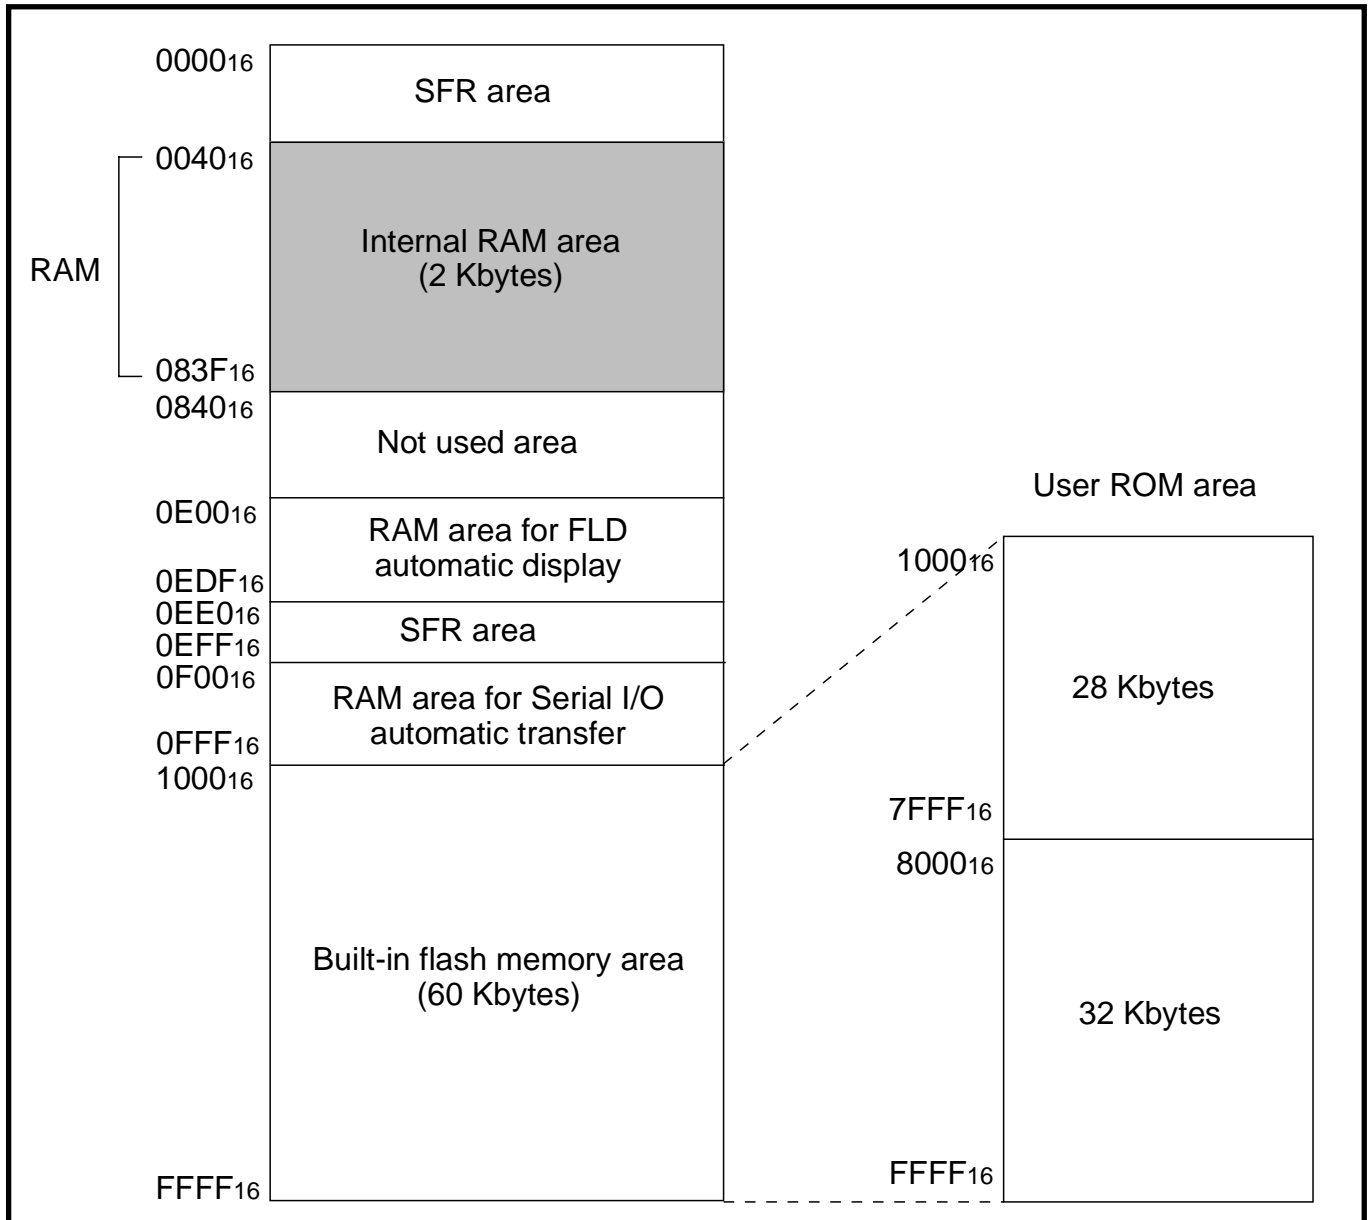

Fig. 2.13.1 Memory map of flash memory version for 38B7 Group

### 2.13.3 Relevant registers

Fig. 2.13.2 Memory map of registers relevant to flash memory

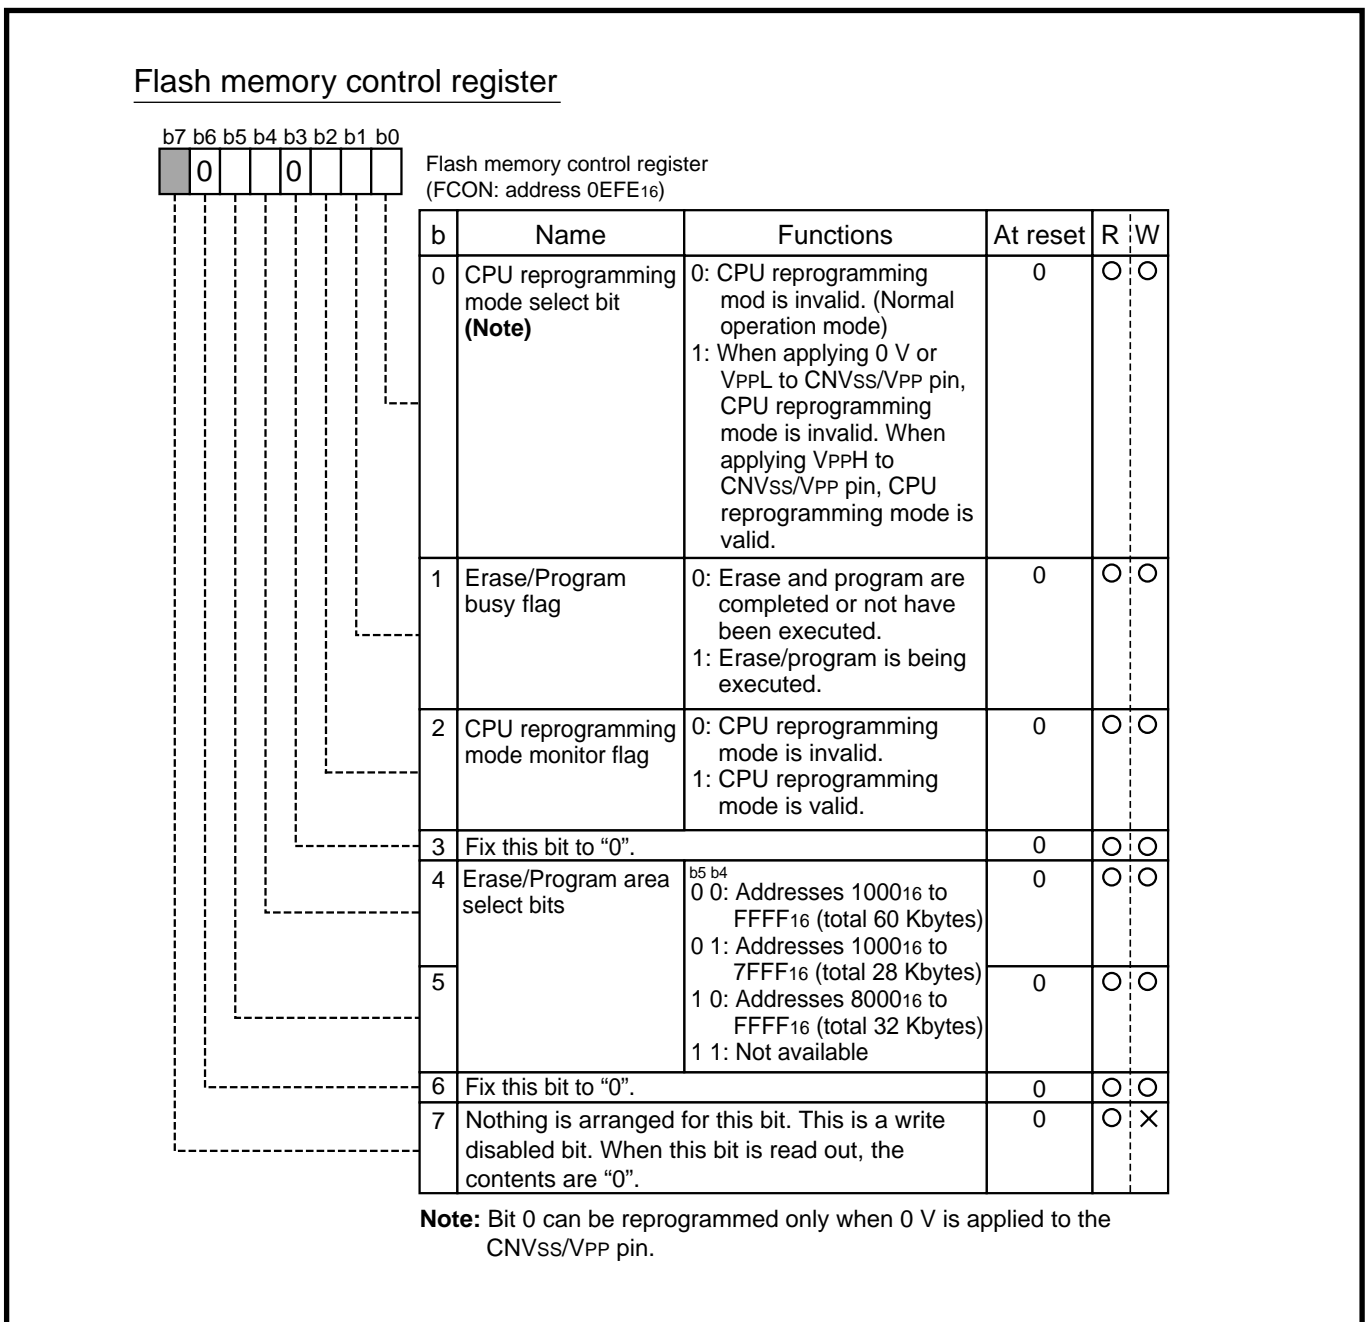

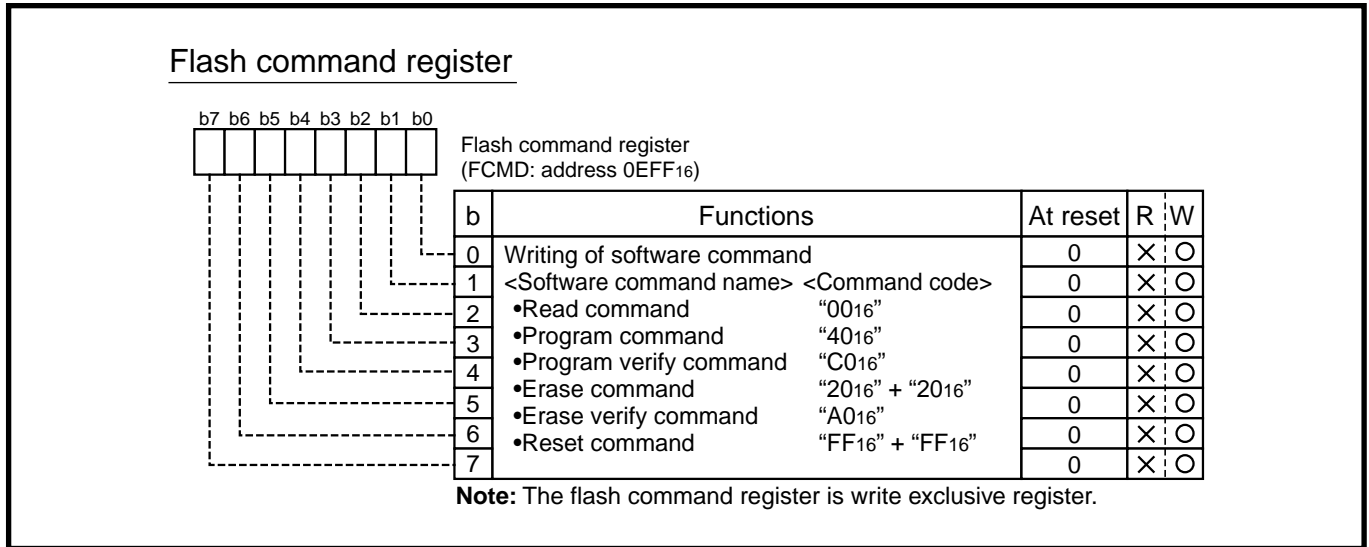

Fig. 2.13.3 Structure of Flash memory control register

# APPLICATION

## 2.13 Flash memory

**Fig. 2.13.4 Structure of Flash command register**

**Fig. 2.13.5 Structure of CPU mode register**

**2.13.4 Parallel I/O mode**

In the parallel I/O mode, program/erase to the built-in flash memory area can be performed by a general EPROM programmer.

Set the programming mode of EPROM programmer to M5M28F101 and the memory area of program/erase to 01000<sub>16</sub> to 0FFFF<sub>16</sub>. Be careful especially when erasing because if the setting of the memory area is mistaken when erasing, the products are damaged eternally.

Table 2.13.1 shows the setting of EPROM programmer when programming in the parallel I/O mode.

Recommended programmer: R4945A provided by ADVANTEST CORPORATION (<http://www.advantest.co.jp/index-e.html>)

**Table 2.13.1 Setting of EPROM programmer when parallel programming**

Products	Programming adapter	Programming mode	Memory area
M38B79FFFP	PCA4738F-100	M5M28F101	01000 <sub>16</sub> to 0FFFF <sub>16</sub>

**2.13.5 Serial I/O mode**

Table 2.13.2 shows the pin connection example using EFP-I\* between the programmer and the microcomputer when programming in the serial I/O mode.

\*EFP-I provided by Suissei Electronics System Co., Ltd. ([http://www.suissei.co.jp/index\\_e.htm](http://www.suissei.co.jp/index_e.htm))  
(Asia and Oceania limited-product)

**Table 2.13.2 Connection example to programmer when serial programming**

EFP-I		38B7 Group flash memory version	
Signal name	Target connector Line number	Pin name	Pin number
BUSY	1	P67/ $\overline{S}$ RDY2/ $\overline{S}$ CLK22/FLD <sub>55</sub>	33
VPP ( <b>Note 1</b> )	2	CNV <sub>SS</sub> ( <b>Note 1</b> )	17
VDD ( <b>Note 3</b> )	3	V <sub>CC</sub> ( <b>Note 3</b> )	24
SCL	4	P66/ $\overline{S}$ CLK21/FLD <sub>54</sub>	34
SDA	5	P64/RxD/FLD <sub>52</sub>	36
PGM/OE	6	P37/FLD <sub>31</sub>	57
RESET	7	$\overline{R}$ ESET	18
GND ( <b>Note 2</b> )	8	V <sub>SS</sub> , AV <sub>SS</sub> ( <b>Note 2</b> )	21, 97

**Notes 1:** Connect an approximate 0.01  $\mu$ F capacitor between CNV<sub>SS</sub>/V<sub>PP</sub> and GND for noise elimination.

**2:** When a serial programmer is connected, at first, connect both GNDs to be the same GND level.

**3:** When the V<sub>CC</sub> power has been already supplied to the target board, do not connect the VDD supply pin of the serial programmer to V<sub>CC</sub> of the target board.

# APPLICATION

## 2.13 Flash memory

---

### 2.13.6 CPU reprogramming mode

In the CPU reprogramming mode, by executing the software command with Central Processing Unit (CPU), the built-in flash memory area can be reprogrammed. Accordingly, the contents of the built-in flash memory area can be reprogrammed with the microcomputer mounted on board, without using the ROM programmer. Program the reprogramming program in advance to the built-in flash memory area. However, in the CPU reprogramming mode, the read from the built-in flash memory cannot be performed. Accordingly, after transferring the reprogramming control program on the internal RAM, not the built-in flash memory, execute it on the RAM.

In the CPU reprogramming mode, read command, program command, program verify command, erase command, erase verify command, and reset command can be used. As for details of each command, refer to “CHAPTER 1 Flash memory mode 3 (CPU reprogramming mode)”.

#### (1) CPU reprogramming mode beginning/release procedure

Operation procedure in the reprogramming mode for the built-in flash memory is described.

As for the control example, refer to “2.13.7 (2) Control example in the CPU reprogramming mode.”

#### [Beginning procedure]

- ① Apply 0 V to the CNV<sub>SS</sub>/V<sub>PP</sub> pin for reset release.
- ② Set the CPU mode register.
- ③ After CPU reprogramming mode control program is transferred to internal RAM, jump to this control program on RAM. (The following operations are controlled by this control program).
- ④ Set “1” to the CPU reprogramming mode select bit (bit 0 of address 0EFE<sub>16</sub>).
- ⑤ Apply V<sub>PPH</sub> to the CNV<sub>SS</sub>/V<sub>PP</sub> pin.
- ⑥ Wait till CNV<sub>SS</sub>/V<sub>PP</sub> pin becomes 12 V.
- ⑦ Read the CPU reprogramming mode monitor flag (bit 2 of address 0EFE<sub>16</sub>) to confirm that the CPU reprogramming mode is valid.
- ⑧ The operation of the flash memory is executed by software-command-writing to the flash command register (address 0EFF<sub>16</sub>).

**Note:** The following are necessary other than this:

- Control for data which is input from the external (serial I/O etc.) and to be programmed to the flash memory.
- Initial setting for ports, etc.
- Writing to the watchdog timer

#### [Release procedure]

- ① Apply 0 V to the CNV<sub>SS</sub>/V<sub>PP</sub> pin.
- ② Wait till CNV<sub>SS</sub>/V<sub>PP</sub> pin becomes 0 V.
- ③ Set the CPU reprogramming mode select bit (bit 0 of address 0EFE<sub>16</sub>) to “0”.

Also, execute the following processing before the CPU reprogramming mode is selected so that interrupts will not occur during the CPU reprogramming mode.

- Set the interrupt disable flag (I) to "1"

In the CPU reprogramming mode, write to the watchdog timer control register (address  $0EEE_{16}$ ) periodically in order not to generate the reset by the underflow of the watchdog timer H.

During the program execution (programming time: max.  $10\ \mu\text{s}$ ), watchdog timer H is set to " $FF_{16}$ ", watchdog timer L is set to " $FF_{16}$ " and the count is stopped. The count is started again after the program is executed or the execution of erase is completed. Accordingly, the setting of write period of the watchdog timer control register is no problem except for the program time and erase time.

When the interrupt request or reset occurs in the CPU reprogramming mode, the microcomputer enters the following state;

- Interrupt occurs

This may cause a program runaway because the read from the flash memory which has the interrupt vector area cannot be performed.

- Underflow of watchdog timer H, reset

This may cause a microcomputer reset; the built-in flash memory control circuit and the flash memory control register are reset.

Also, when the above interrupt and reset occur during program/erase, error data may still exist after reset release because the reprogramming of the flash memory is not completed, so that be careful. In this case, reprogramming of the flash memory in the parallel I/O mode or serial I/O mode is required.

### 2.13.7 Flash memory mode application examples

The control pin processing example on the system board in the serial I/O mode and the control example in the CPU reprogramming mode are described below.

#### (1) Control pin processing example on the system board in serial I/O mode

As shown in Figure 2.13.6, in the serial I/O mode, the contents of the built-in flash memory can be reprogrammed with the microcomputer mounted on board. In the serial I/O mode, the processing example of control pins (P37, P64, P66, P67, CNV<sub>SS</sub> and  $\overline{\text{RESET}}$  pin) is described below.

Fig. 2.13.6 Reprogramming example of built-in flash memory by serial I/O mode

# APPLICATION

## 2.13 Flash memory

### ① When control signals are not affected to user system circuit

When the control signals in the serial I/O mode are not used or not affected to the user system circuit, they can be connected as shown in Figure 2.13.7.

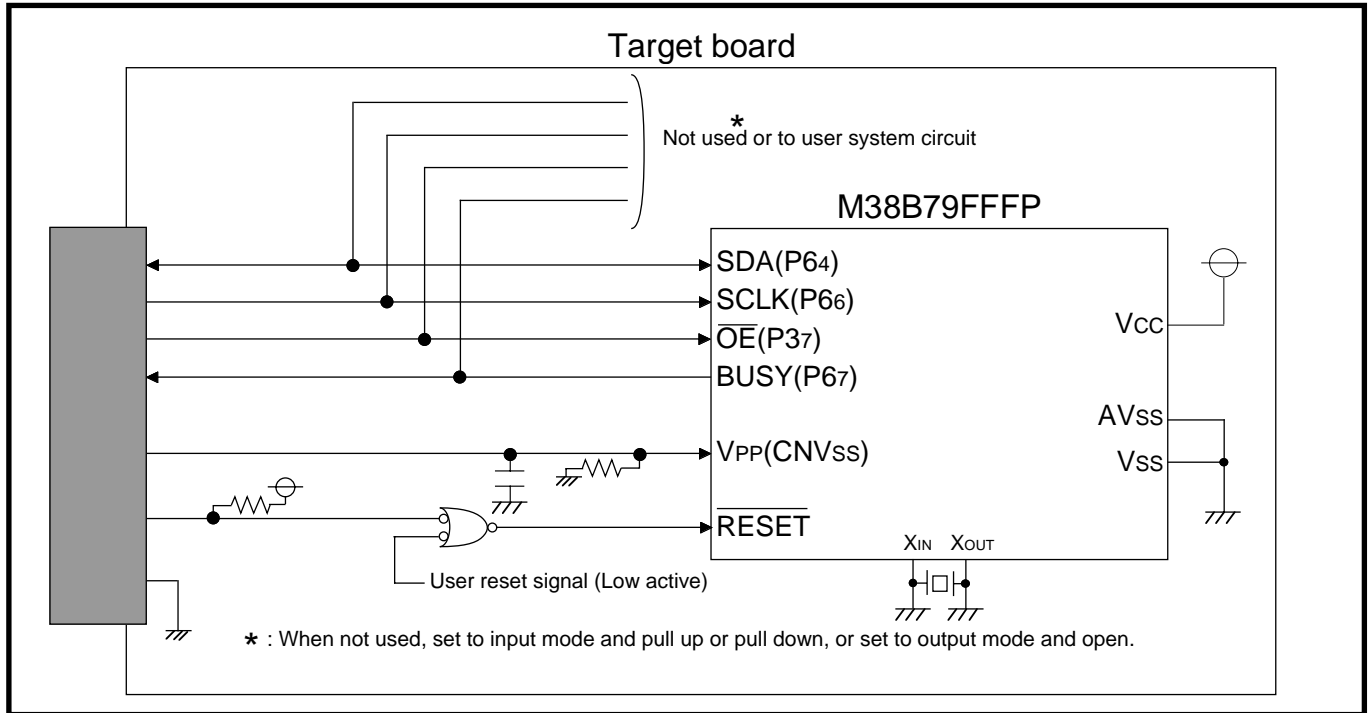

Fig. 2.13.7 Processing example of pins on board in serial I/O mode (1)

### ② When control signals are affected to user system circuit-1

Figure 2.13.8 shows the example that the control signals supplied to the user system circuit are cut-off by a jumper switch in the serial I/O mode.

Fig. 2.13.8 Processing example of pins on board in serial I/O mode (2)

### ③ When control signals are affected to user system circuit-2

Figure 2.13.9 shows the example that the control signals supplied to the user system circuit are cut-off by an analog switch (74HC4066) in the serial I/O mode.

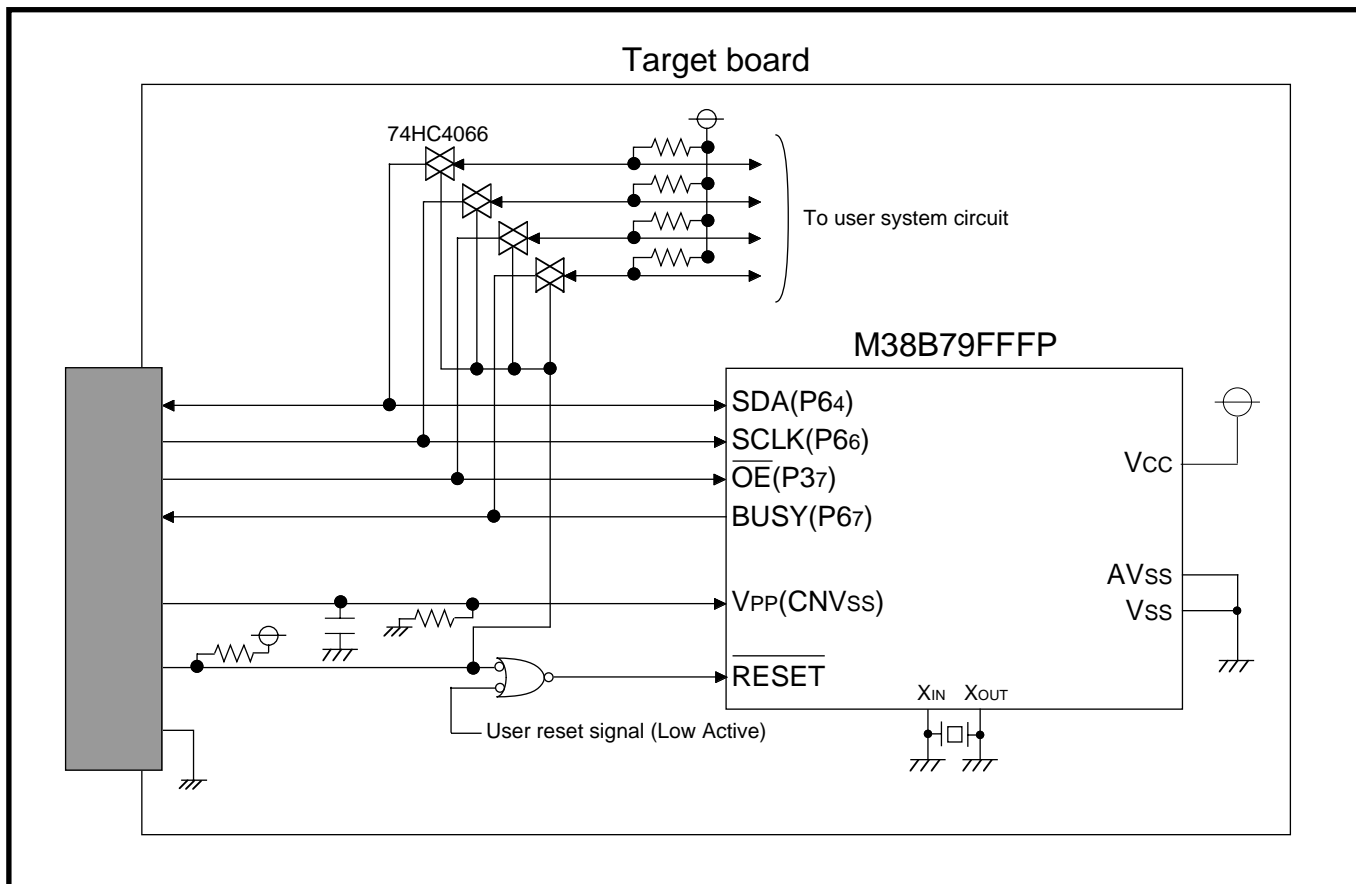

Fig. 2.13.9 Processing example of pins on board in serial I/O mode (3)

# APPLICATION

## 2.13 Flash memory

### (2) Control example in CPU reprogramming mode

In this example, the built-in flash memory is reprogrammed in the CPU reprogramming mode by serial I/O2, receiving the reprogramming data (updated data).

Figure 2.13.10 shows the example for the reprogramming system of the built-in flash memory by the CPU reprogramming mode.

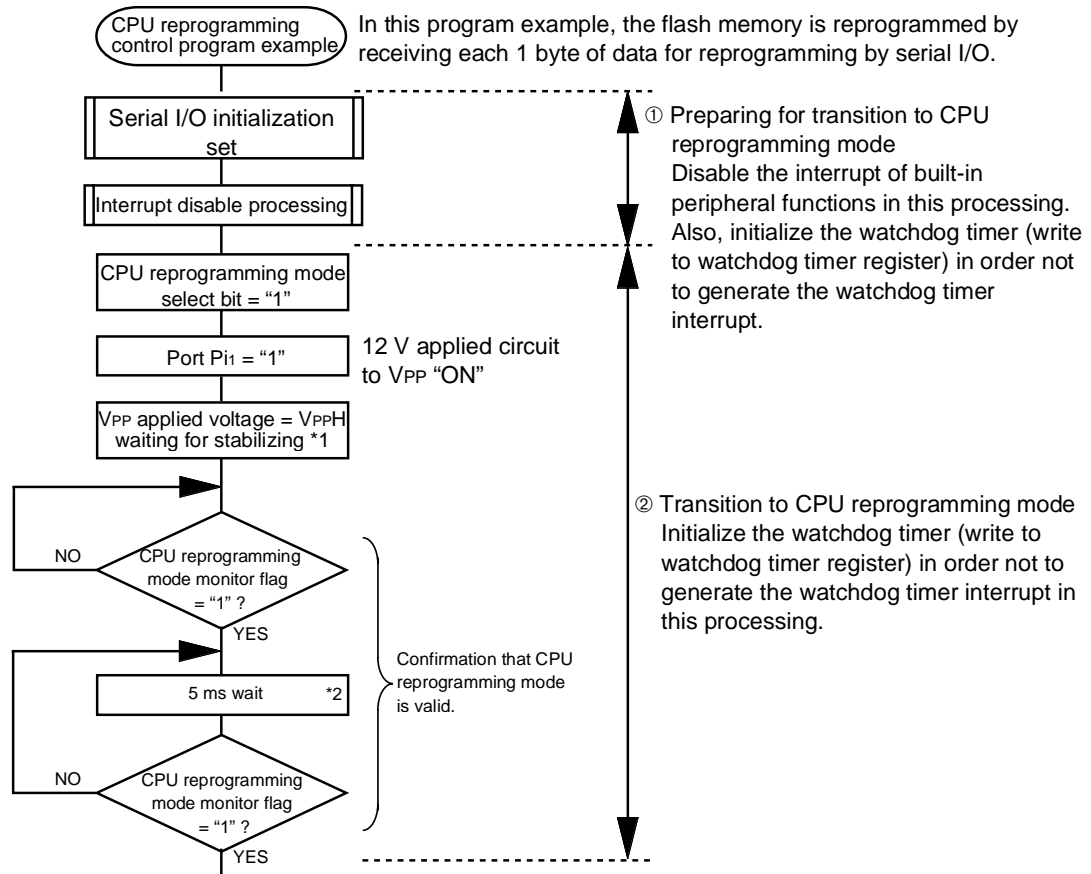

Fig. 2.13.10 Example for reprogramming system of built-in flash memory by CPU reprogramming mode

### ● Specifications

- ① CPU reprogramming mode is selected/released by the input signal to Pi2.
- ② Updated data is received by serial I/O2.
- ③ The transfer enable state of serial transmit side is judged by "L" level input to Pi0.
- ④ V<sub>PP</sub> control circuit is turned ON/OFF by the output from Pi1 (refer to Figure 2.13.15 and Figure 2.13.16).

**Note:** In this example, the following program is transferred to the internal RAM and executed on the internal RAM.

Continue to “CPU reprogramming control program example (2)” to the next page.

\*1: Waiting by software until VPP input voltage is stabilized at VPPH is recommended. (Refer to Figure 2.13.15 and Figure 2.13.16 VPP voltage control timing (A).)

\*2: The wait time depends on VPP control circuit (Refer to Figure 2.13.15 and Figure 2.13.16 VPP voltage control timing (C).)

---

### 2.13.8 Notes on CPU reprogramming mode

- (1) Transfer the CPU reprogramming mode control program to the internal RAM before selecting the CPU reprogramming mode, and then, execute it on the internal RAM. Additionally, when the subroutine or stack operation instruction is used in the control program, make sure in order not to destroy the control program transferred to the internal RAM through the stack area.
- (2) Be careful of the instruction description (specifying address, and so on) because the CPU reprogramming mode control program is transferred to the internal RAM and executed on the internal RAM.
- (3) Write to the watchdog timer control register periodically in order not to generate the watchdog timer interrupt by the CPU reprogramming mode control program (refer to “**2.9 Watchdog timer**”).

### 2.13.9 Notes on flash memory version

The CNV<sub>SS</sub> pin is connected to the internal memory circuit block by a low-ohmic resistance, since it has the multiplexed function to be a programmable power source pin (V<sub>PP</sub> pin) as well.

To improve the noise margin, connect the CNV<sub>SS</sub> pin to V<sub>SS</sub> through 1 to 10 kΩ resistance.

Even when the wiring of the CNV<sub>SS</sub> pin of the mask ROM version is connected to V<sub>SS</sub> through this resistor, that will not affect operation.

$\Sigma I_{OL}(\text{avg})$	“L” total average output current ( <b>Note 1</b> ) P64–P67, P70–P77, P80–P83, P90–P97, PA0–PA7, PB0–PB6			50	mA
$I_{OH}(\text{peak})$	“H” peak output current ( <b>Note 2</b> ) P00–P07, P10–P17, P20–P27, P30–P37, P40–P47, P50–P57, P60–P63			–40	mA
$I_{OH}(\text{peak})$	“H” peak output current ( <b>Note 2</b> ) P64–P67, P70–P77, P80–P83, P90–P97, PA0–PA7, PB0–PB6			–10	mA
$I_{OL}(\text{peak})$	“L” peak output current ( <b>Note 2</b> ) P64–P67, P70–P77, P80–P83, P90–P97, PA0–PA7, PB0–PB6			10	mA
$I_{OH}(\text{avg})$	“H” average output current ( <b>Note 3</b> ) P00–P07, P10–P17, P20–P27, P30–P37, P40–P47, P50–P57, P60–P63			–18	mA
$I_{OH}(\text{avg})$	“H” average output current ( <b>Note 3</b> ) P64–P67, P70–P77, P80–P83, P90–P97, PA0–PA7, PB0–PB6			–5	mA
$I_{OL}(\text{avg})$	“L” average output current ( <b>Note 3</b> ) P64–P67, P70–P77, P80–P83, P90–P97, PA0–PA7, PB0–PB6			5	mA
$f(\text{CNTR})$	Clock input frequency for timers 2, 4, and X (duty cycle 50 %)			250	kHz
$f(X_{IN})$	Main clock input oscillation frequency ( <b>Note 4</b> )			4.2	MHz
$f(X_{CIN})$	Sub-clock input oscillation frequency ( <b>Notes 4, 5</b> )		32.768	50	kHz

**Notes 1:** The total output current is the sum of all the currents flowing through all the applicable ports. The total average current is an average value measured over 100 ms. The total peak current is the peak value of all the currents.

**2:** The peak output current is the peak current flowing in each port.

**3:** The average output current  $I_{OL}(\text{avg})$ ,  $I_{OH}(\text{avg})$  are average value measured over 100 ms.

**4:** When the oscillation frequency has a duty cycle of 50%.

**5:** When using the microcomputer in low-speed mode, set the sub-clock input oscillation frequency on condition that  $f(X_{CIN}) < f(X_{IN})/3$ .

# APPENDIX

## 3.2 Standard characteristics

### 3.2.3 A-D conversion standard characteristics

Figure 3.2.9 shows the A-D conversion standard characteristics.

The lower line on the graph indicates the absolute precision error. It expresses the deviation from the ideal value. For example, the conversion of output code from  $00_{16}$  to  $01_{16}$  occurs ideally at the point of  $AN_0 = 2.5$  mV, but the measured value is  $-2$  mV. Accordingly, the measured point of conversion is defined as " $2.5 - 2 = 0.5$  mV".

The upper line on the graph indicates the width of input voltages equivalent to output codes. For example, the measured width of the input voltage for output code  $60_{16}$  is 6 mV, so that the differential nonlinear error is defined as " $6 - 5 = 1$  mV (0.2 LSB)".

Fig. 3.2.9 A-D conversion standard characteristics

### 3.3 Notes on use

#### 3.3.1 Notes on interrupts

##### (1) Change of relevant register settings

When switching an active edge of an external interrupt or switching an interrupt sources of an interrupt vector address where two or more interrupt sources are allocated, the interrupt request bit may be set to "1". When not requiring the interrupt occurrence synchronized with these setting, take the following sequence.

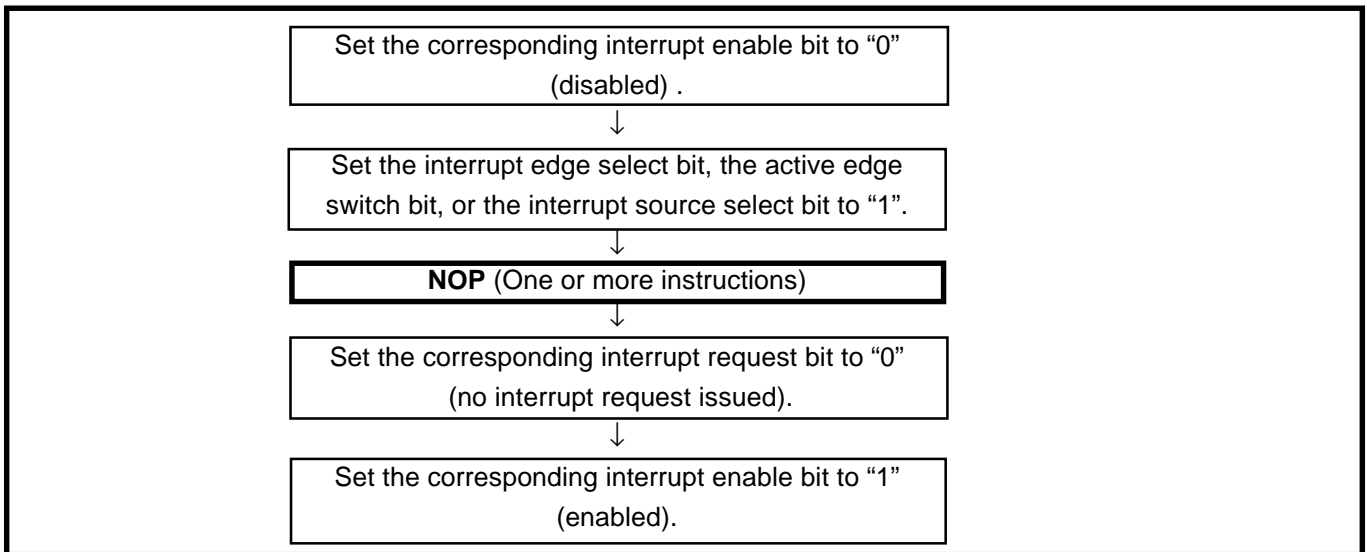

Fig. 3.3.1 Setting procedure of relevant registers

##### ■ Reason

When setting the followings, the interrupt request bit may be set to "1".

- When switching external interrupt active edge

Related register: Interrupt edge selection register (address 3A<sub>16</sub>)

- When switching interrupt sources of an interrupt vector address where two or more interrupt sources are allocated

Related register: Interrupt source switch register (address 39<sub>16</sub>)

##### (2) Check of interrupt request bit

- When executing the **BBC** or **BBS** instruction to an interrupt request bit of an interrupt request register immediately after this bit is set to "0" by using a data transfer instruction, execute one or more instructions before executing the **BBC** or **BBS** instruction.

##### ■ Reason

If the **BBC** or **BBS** instruction is executed immediately after an interrupt request bit of an interrupt request register is cleared to "0", the value of the interrupt request bit before being cleared to "0" is read.

# APPENDIX

## 3.3 Notes on use

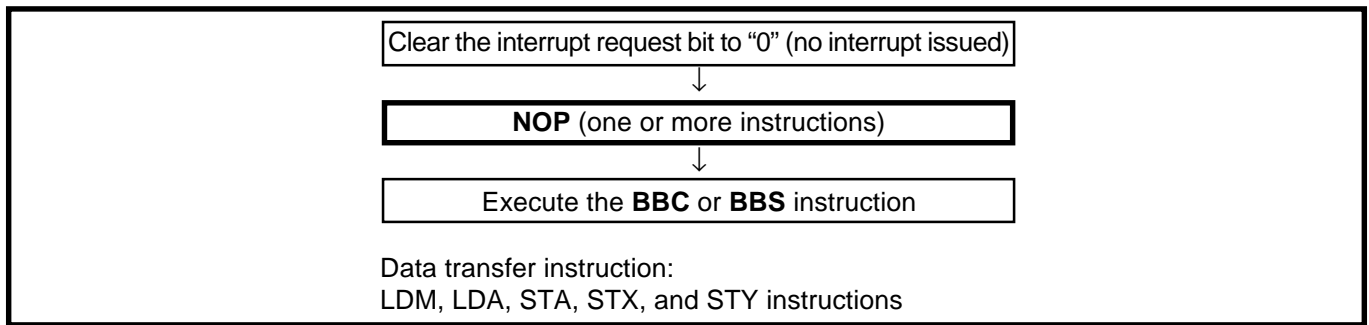

Fig. 3.3.2 Sequence of check of interrupt request bit

### (3) Structure of interrupt control register 2

Fix the bit 7 of the interrupt control register 2 to "0". Figure 3.3.3 shows the structure of the interrupt control register 2.

Fig. 3.3.3 Structure of interrupt control register 2

### 3.3.2 Notes on I/O port

#### (1) Notes in standby state

In standby state\*1 for low-power dissipation, do not make input levels of an input port and an I/O port "undefined".

Pull-up (connect the port to VCC) or pull-down (connect the port to VSS) these ports through a resistor.

When determining a resistance value, note the following points:

- External circuit
- Variation of output levels during the ordinary operation

When using an optional built-in pull-up resistor, note on varied current values:

- When setting as an input port : Fix its input level
- When setting as an output port : Prevent current from flowing out to external

#### ● Reason

The potential which is input to the input buffer in a microcomputer is unstable in the state that input levels of a input port and an I/O port are "undefined". This may cause power source current.

\*1 standby state: stop mode by executing **STP** instruction  
wait mode by executing **WIT** instruction

#### (2) Modifying port latch of I/O port with bit managing instruction

When the port latch of an I/O port is modified with the bit managing instruction\*2, the value of the unspecified bit may be changed.

#### ● Reason

The bit managing instructions are read-modify-write form instructions for reading and writing data by a byte unit. Accordingly, when these instructions are executed on a bit of the port latch of an I/O port, the following is executed to all bits of the port latch.

- As for bit which is set for input port:  
The pin state is read in the CPU, and is written to this bit after bit managing.
- As for bit which is set for output port:  
The bit value is read in the CPU, and is written to this bit after bit managing.

Note the following:

- Even when a port which is set as an output port is changed for an input port, its port latch holds the output data.
- As for a bit of which is set for an input port, its value may be changed even when not specified with a bit managing instruction in case where the pin state differs from its port latch contents.

\*2 Bit managing instructions: **SEB** and **CLB** instructions

### (3) Pull-up/Pull-down control

When each port which has built-in pull-up/pull-down resistor is set to output port, pull-up/pull-down control of corresponding port becomes invalid. (Pull-up/pull-down cannot be set.)

#### ● Reason

Pull-up/pull-down control is valid only when each direction register is set to the input mode.

### 3.3.3 Notes on serial I/O1

#### (1) Clock

##### ■ Using internal clock

After setting the synchronous clock to an internal clock, clear the serial I/O interrupt request bit before perform the normal serial I/O transfer or the serial I/O automatic transfer.

##### ■ Using external clock

After inputting "H" level to the external clock input pin, clear the serial I/O interrupt request bit before performing the normal serial I/O transfer or the serial I/O automatic transfer.

#### (2) Using serial I/O1 interrupt

Clear bit 3 of the interrupt request register 1 to "0" by software before enabling interrupts.

#### (3) State of S<sub>OUT1</sub> pin

The S<sub>OUT1</sub> pin control bit of the serial I/O1 control register 2 can be used to select the state of the S<sub>OUT1</sub> pin when serial data is not transferred; either output active or high-impedance. However, when selecting an external synchronous clock; the S<sub>OUT1</sub> pin can become the high-impedance state by setting the S<sub>OUT1</sub> pin control bit to "1" when the serial I/O1 clock input is at "H" after transfer completion.

#### (4) Serial I/O initialization bit

- Set "0" to the serial I/O initialization bit of the serial I/O1 control register 1 when terminating a serial transfer during transferring.
- When writing "1" to the serial I/O initialization bit, the serial I/O1 is enabled, but each register is not initialized. Set the value of each register by program.

# APPENDIX

## 3.3 Notes on use

---

### (5) Handshake signal

#### ■ $S_{BUSY1}$ input signal

Input an “H” level to the  $S_{BUSY1}$  input and an “L” level signal to the  $\overline{S_{BUSY1}}$  input in the initial state. When the external synchronous clock is selected, switch the input level to the  $S_{BUSY1}$  input and the  $\overline{S_{BUSY1}}$  input while the serial I/O1 clock input is in “H” state.

#### ■ $S_{RDY1}$ input•output signal

When selecting the internal synchronous clock, input an “L” level to the  $S_{RDY1}$  input and an “H” level signal to the  $\overline{S_{RDY1}}$  input in the initial state.

### (6) 8-bit serial I/O mode

#### ■ When selecting external synchronous clock

When an external synchronous clock is selected, the contents of the serial I/O1 register are being shifted continually while the transfer clock is input to the serial I/O1 clock pin. In this case, control the clock externally.

### (7) In automatic transfer serial I/O mode

#### ■ Set of automatic transfer interval

- When the  $S_{BUSY1}$  output is used, and the  $S_{BUSY1}$  output and the  $S_{STB1}$  output function as signals for each transfer data set by the  $S_{BUSY1}$  output• $S_{STB1}$  output function selection bit of serial I/O1 control register 2; the transfer interval is inserted before the first data is transmitted/received, and after the last data is transmitted/received. Accordingly, regardless of the contents of the  $S_{BUSY1}$  output• $S_{STB1}$  output function selection bit, this transfer interval for each 1-byte data becomes 2 cycles longer than the value set by the automatic transfer interval set bits of serial I/O1 control register 3.
- When using the  $S_{STB1}$  output, regardless of the contents of the  $S_{BUSY1}$  output• $S_{STB1}$  output function selection bit, this transfer interval for each 1-byte data becomes 2 cycles longer than the value set by the automatic transfer interval set bits of serial I/O1 control register 3.
- When using the combined output of  $S_{BUSY1}$  and  $S_{STB1}$  as the signal for each of all transfer data set, the transfer interval after completion of transmission/reception of the last data becomes 2 cycles longer than the value set by the automatic transfer interval set bits.
- When selecting an external clock, the set of automatic transfer interval becomes invalid.
- Set the transfer interval of each 1-byte data transfer as the following:

##### (1) Not using FLD controller

Keep the interval for 5 cycles or more of internal system clock from clock rising of the last bit of 1-byte data.

##### (2) Using FLD controller

###### (a) Not using gradation display

Keep the interval for 17 cycles or more of internal system clock from clock rising of the last bit of 1-byte data.

###### (b) Using gradation display

Keep the interval for 27 cycles or more of internal system clock from clock rising of the last bit of 1-byte data.

#### ■ Set of serial I/O1 transfer counter

- Write the value decreased by 1 from the number of transfer data bytes to the serial I/O1 transfer counter.
- When selecting an external clock, after writing a value to the serial I/O1 register/transfer counter, wait for 5 or more cycles of internal system clock before inputting the transfer clock to the serial I/O1 clock pin.

#### ■ Serial I/O initialization bit

A serial I/O1 automatic transfer interrupt request occurs when “0” is written to the serial I/O initialization bit during an operation. Disable it with the interrupt enable bit as necessary by program.

**Table 3.3.1 SIO1CON3 (address 001C<sub>16</sub>) setting example selecting internal synchronous clock**

Serial I/O1 control register 3, SIO1CON3 (address 001C <sub>16</sub> )		Not using FLDC	Not using gradation display mode	Using gradation display mode
Internal synchronous clock selection bits (b7 to b5)	Automatic transfer interval set bits (b4 to b0)			
0 0 0 : f(XIN) / 4	0 0 0 0 0 : 2 cycles of transfer clocks	Usable	Prohibited	Prohibited
	0 0 0 0 1 : 3 cycles of transfer clocks	Usable	Prohibited	Prohibited
	0 0 0 1 0 : 4 cycles of transfer clocks	Usable	Prohibited	Prohibited
	0 0 0 1 1 : 5 cycles of transfer clocks	Usable	Usable	Usable
0 0 1 : f(XIN) / 8	0 0 0 0 0 : 2 cycles of transfer clocks	Usable	Prohibited	Prohibited
	0 0 0 0 1 : 3 cycles of transfer clocks	Usable	Usable	Usable
0 1 0 : f(XIN) / 16	0 0 0 0 0 : 2 cycles of transfer clocks	Usable	Usable	Usable

**Table 3.3.2 SIO1CON3 (address 001C<sub>16</sub>) setting example selecting external synchronous clock**

Serial I/O1 control register 3, SIO1CON3 (address 001C <sub>16</sub> ), Automatic transfer interval set bits	"n" cycles of transfer clocks
Not using FLDC	Transfer clock X n cycles ≥ 5 cycles of internal system clock
Not using gradation display mode	Transfer clock X n cycles ≥ 17 cycles of internal system clock
Using gradation display mode	Transfer clock X n cycles ≥ 27 cycles of internal system clock

### 3.3.4 Notes on serial I/O2

#### (1) Notes when selecting clock synchronous serial I/O

##### ① Stop of transmission operation

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, clear the transmit enable bit to "0" (transmit disabled).

##### ● Reason

Since transmission is not stopped and the transmission circuit is not initialized even if only the serial I/O2 enable bit is cleared to "0" (serial I/O2 disabled), the internal transmission is running (in this case, since pins Tx<sub>D</sub>, Rx<sub>D</sub>, S<sub>CLK21</sub>, S<sub>CLK22</sub> and S<sub>RDY2</sub> function as I/O ports, the transmission data is not output). When data is written to the transmit buffer register in this state, data starts to be shifted to the transmit shift register. When the serial I/O2 enable bit is set to "1" at this time, the data during internally shifting is output to the Tx<sub>D</sub> pin and an operation failure occurs.

##### ② Stop of receive operation

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, clear the receive enable bit to "0" (receive disabled), or clear the serial I/O2 enable bit to "0" (serial I/O2 disabled).

##### ③ Stop of transmit/receive operation

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, simultaneously clear both the transmit enable bit and receive enable bit to "0" (transmit and receive disabled).

(when data is transmitted and received in the clock synchronous serial I/O mode, any one of data transmission and reception cannot be stopped.)

##### ● Reason

In the clock synchronous serial I/O mode, the same clock is used for transmission and reception. If any one of transmission and reception is disabled, a bit error occurs because transmission and reception cannot be synchronized.

In this mode, the clock circuit of the transmission circuit also operates for data reception. Accordingly, the transmission circuit does not stop by clearing only the transmit enable bit to "0" (transmit disabled). Also, the transmission circuit is not initialized by clearing the serial I/O2 enable bit to "0" (serial I/O2 disabled) (refer to (1), ①).

# APPENDIX

## 3.3 Notes on use

### (2) Notes when selecting clock asynchronous serial I/O

#### ① Stop of transmission operation

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, clear the transmit enable bit to “0” (transmit disabled).

#### ● Reason

Since transmission is not stopped and the transmission circuit is not initialized even if only the serial I/O2 enable bit is cleared to “0” (serial I/O2 disabled), the internal transmission is running (in this case, since pins TxD, RxD, S<sub>CLK21</sub>, S<sub>CLK22</sub> and S<sub>RDY2</sub> function as I/O ports, the transmission data is not output). When data is written to the transmit buffer register in this state, data starts to be shifted to the transmit shift register. When the serial I/O2 enable bit is set to “1” at this time, the data during internally shifting is output to the TxD pin and an operation failure occurs.

#### ② Stop of receive operation

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, clear the receive enable bit to “0” (receive disabled).

#### ③ Stop of transmit/receive operation

##### Only transmission operation is stopped.

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, clear the transmit enable bit to “0” (transmit disabled).

#### ● Reason

Since transmission is not stopped and the transmission circuit is not initialized even if only the serial I/O2 enable bit is cleared to “0” (serial I/O2 disabled), the internal transmission is running (in this case, since pins TxD, RxD, S<sub>CLK21</sub>, S<sub>CLK22</sub> and S<sub>RDY2</sub> function as I/O ports, the transmission data is not output). When data is written to the transmit buffer register in this state, data starts to be shifted to the transmit shift register. When the serial I/O2 enable bit is set to “1” at this time, the data during internally shifting is output to the TxD pin and an operation failure occurs.

##### Only receive operation is stopped.

As for the serial I/O2 that can be used as either a clock synchronous or an asynchronous (UART) serial I/O, clear the receive enable bit to “0” (receive disabled).

### (3) S<sub>RDY2</sub> output of reception side

When signals are output from the S<sub>RDY2</sub> pin on the reception side by using an external clock in the clock synchronous serial I/O mode, set all of the receive enable bit, the S<sub>RDY2</sub> output enable bit, and the transmit enable bit to “1” (transmit enabled).

### (4) Setting serial I/O2 control register again

Set the serial I/O2 control register again after the transmission and the reception circuits are reset by clearing both the transmit enable bit and the receive enable bit to “0.”

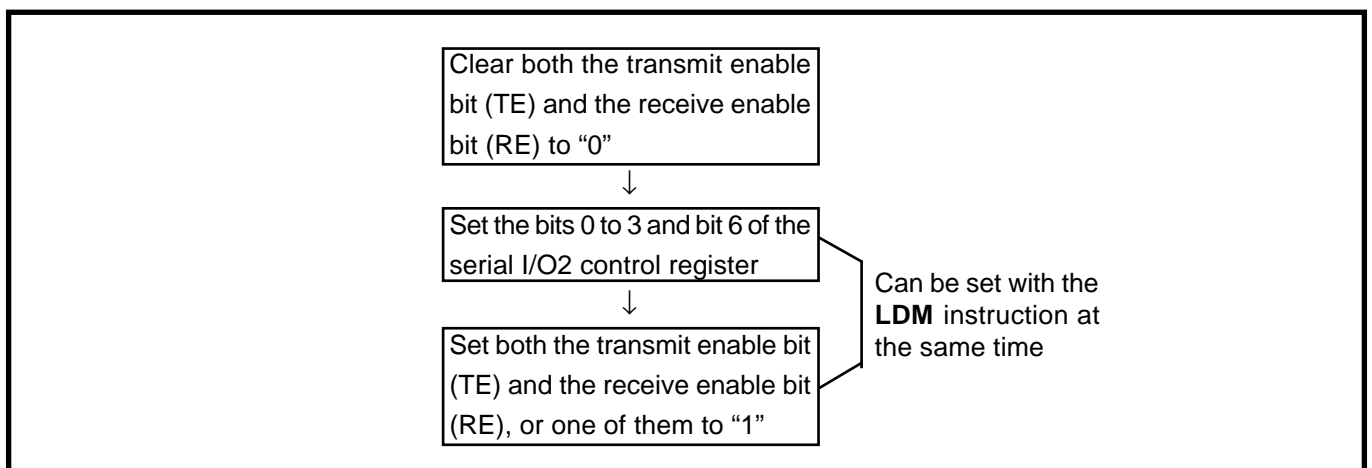

Fig. 3.3.4 Sequence of setting serial I/O2 control register again

**(5) Data transmission control with referring to transmit shift register completion flag**

The transmit shift register completion flag changes from “1” to “0” with a delay of 0.5 to 1.5 shift clocks. When data transmission is controlled with referring to the flag after writing the data to the transmit buffer register, note the delay.

**(6) Transmission control when external clock is selected**

When an external clock is used as the synchronous clock for data transmission, set the transmit enable bit to “1” at “H” of the serial I/O2 clock input level. Also, write the transmit data to the transmit buffer register (serial I/O shift register) at “H” of the serial I/O2 clock input level.

**(7) Setting procedure when serial I/O2 transmit interrupt is used**

When setting the transmit enable bit to “1”, the serial I/O2 transmit interrupt request bit is automatically set to “1”. When not requiring the interrupt occurrence synchronized with the transmission enabled, take the following sequence.

- ① Set the serial I/O1 transmit interrupt enable bit to “0” (disabled).
- ② Set the transmit enable bit to “1”.
- ③ Set the serial I/O1 transmit interrupt request bit to “0” after 1 or more instructions have been executed.
- ④ Set the serial I/O1 transmit interrupt enable bit to “1” (enabled).

**(8) Using TxD pin**

The P6<sub>s</sub>/TxD P-channel output disable bit of UART control register is valid in both cases: using as a normal I/O port and as the TxD pin. Do not supply V<sub>cc</sub> + 0.3 V or more even when using the P6<sub>s</sub>/TxD pin as an N-channel open-drain output.

Additionally, in the serial I/O2, the TxD pin latches the last bit and continues to output it after completing transmission.

### 3.3.5 Notes on FLD controller

- Set a value of 03<sub>16</sub> or more to the Toff1 time set register.
- When displaying in the gradation display mode, select the 16 timing mode by the timing number control bit (bit 4 of FLDC mode register (address 0EF4<sub>16</sub>) = “0”).

# APPENDIX

## 3.3 Notes on use

### 3.3.6 Notes on A-D converter

#### (1) Analog input pin

- Make the signal source impedance for analog input low, or equip an analog input pin with an external capacitor of 0.01  $\mu\text{F}$  to 1  $\mu\text{F}$ . Further, be sure to verify the operation of application products on the user side.

#### ● Reason

An analog input pin includes the capacitor for analog voltage comparison. Accordingly, when signals from signal source with high impedance are input to an analog input pin, charge and discharge noise generates. This may cause the A-D conversion precision to be worse.

#### (2) A-D converter power source pin

The AVSS pin is A-D converter power source pin. Regardless of using the A-D conversion function or not, connect it as following :

- AVSS : Connect to the VSS line

#### ● Reason

If the AVSS pin is opened, the microcomputer may have a failure because of noise or others.

#### (3) Clock frequency during A-D conversion

The comparator consists of a capacity coupling, and a charge of the capacity will be lost if the clock frequency is too low. Thus, make sure the following during an A-D conversion.

- $f(\text{XIN})$  is 250 kHz or more
- Do not execute the **STP** instruction and **WIT** instruction

### 3.3.7 Notes on D-A converter

#### (1) PB<sub>0</sub>/DA state at reset

The PB<sub>0</sub>/DA pin becomes a high-impedance state at reset.

#### (2) Connection with low-impedance load

If connecting a D-A output with a load having a low impedance, use an external buffer. It is because the D-A converter circuit does not include a buffer.

#### (3) Usable voltage

Vcc must be 3.0 V or more when using the D-A converter.

### 3.3.8 Notes on PWM

- For PWM<sub>0</sub> output, "L" level is output first.
- After data is set to the PWM register (low-order) and the PWM register (high-order), PWM waveform corresponding to new data is output from next repetitive cycle.

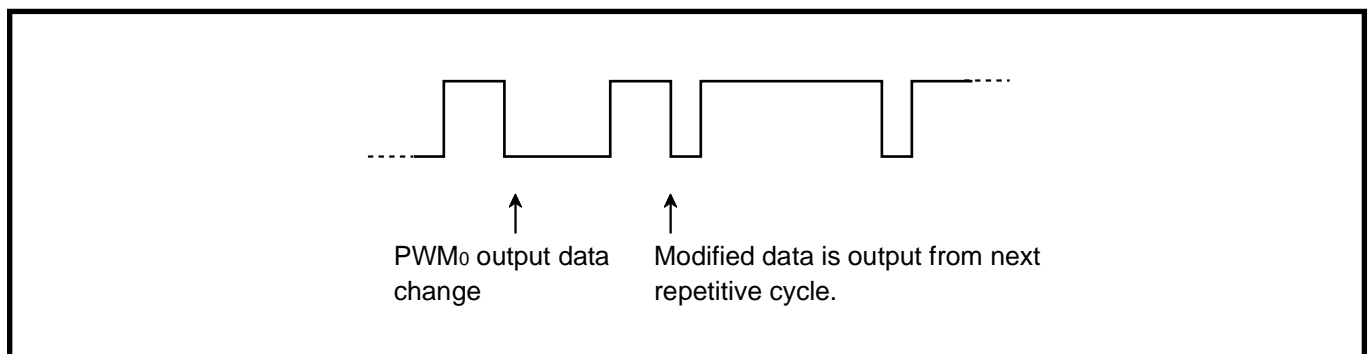

Fig. 3.3.5 PWM<sub>0</sub> output

### 3.3.9 Notes on watchdog timer

- The watchdog timer continues to count even while waiting for stop release. Accordingly, make sure that watchdog timer does not underflow during this term by writing to the watchdog timer control register (address 0EEE<sub>16</sub>) once before executing the STP instruction, etc.
- Once a “1” is written to the STP instruction disable bit (bit 6) of the watchdog timer control register (address 0EEE<sub>16</sub>), it cannot be programmed to “0” again. This bit becomes “0” after reset.

### 3.3.10 Notes on reset

#### (1) Reset input voltage control

Make sure that the reset input voltage is 0.5 V or less for V<sub>cc</sub> of 2.7 V.

Perform switch to the high-speed mode when power source voltage is within 4.0 to 5.5 V.

#### (2) Countermeasure when RESET signal rise time is long

In case where the RESET signal rise time is long, connect a ceramic capacitor or others across the RESET pin and the V<sub>ss</sub> pin. And use a 1000 pF or more capacitor for high frequency use. When connecting the capacitor, note the following :

- Make the length of the wiring which is connected to a capacitor as short as possible.
- Be sure to verify the operation of application products on the user side.

#### ● Reason

If the several nanosecond or several ten nanosecond impulse noise enters the RESET pin, it may cause a microcomputer failure.

### 3.3.11 Each port state during “L” state of RESET pin

Table 3.3.3 shows a pin state during “L” state of RESET pin.

**Table 3.3.3 Pin state during “L” state of RESET pin**

Pin name	Pin state
P0, P2	Output port (with pull-down resistor)
P1, P3	Input port (with pull-down resistor)
P4, P5, P6 <sub>0</sub> to P6 <sub>3</sub>	Input port (without pull-down resistor) ( <b>Note</b> )
P6 <sub>4</sub> to P6 <sub>7</sub> , P7, P8 <sub>0</sub> to P8 <sub>3</sub> , P9, PA, PB <sub>0</sub> to PB <sub>6</sub>	Input port (floating)

**Note:** Whether built-in pull-down resistors are connected or not can be specified in ordering mask ROM.

# APPENDIX

## 3.3 Notes on use

---

### 3.3.12 Notes on programming

#### (1) Processor status register

##### ① Initializing of processor status register

Flags which affect program execution must be initialized after a reset. In particular, it is essential to initialize the T and D flags because they have an important effect on calculations.

##### ● Reason

After a reset, the contents of the processor status register (PS) are undefined except for the I flag which is "1".

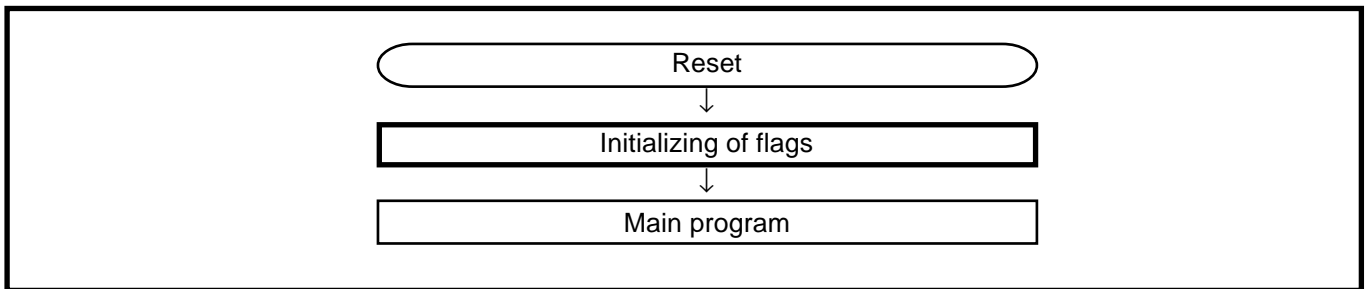

Fig. 3.3.6 Initialization of processor status register

##### ② How to reference the processor status register

To reference the contents of the processor status register (PS), execute the **PHP** instruction once then read the contents of (S+1). If necessary, execute the **PLP** instruction to return the PS to its original status.

A **NOP** instruction should be executed after every **PLP** instruction.

Fig. 3.3.7 Sequence of PLP instruction execution

Fig. 3.3.8 Stack memory contents after PHP instruction execution

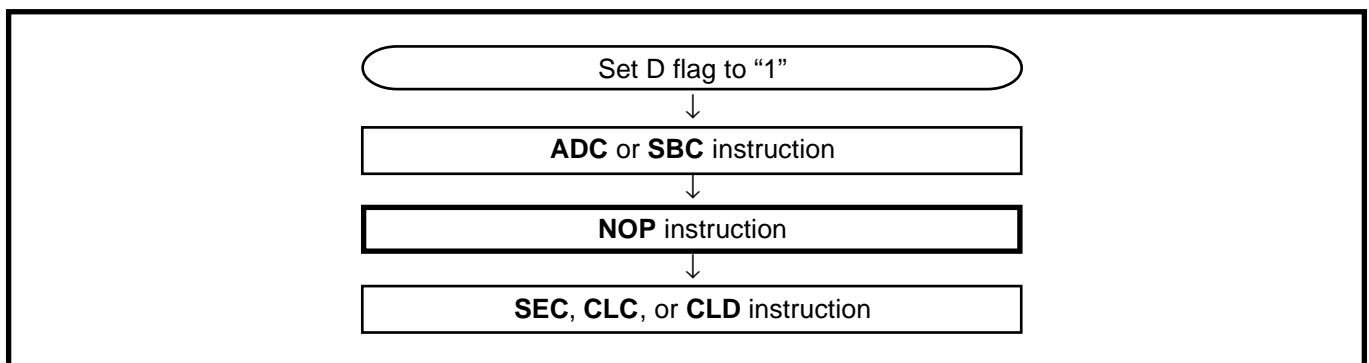

**(2) Decimal calculations****① Execution of decimal calculations**

The **ADC** and **SBC** are the only instructions which will yield proper decimal notation, set the decimal mode flag (D) to “1” with the **SED** instruction. After executing the **ADC** or **SBC** instruction, execute another instruction before executing the **SEC**, **CLC**, or **CLD** instruction.

**② Notes on status flag in decimal mode**

When decimal mode is selected, the values of three of the flags in the status register (the N, V, and Z flags) are invalid after a **ADC** or **SBC** instruction is executed.

The carry flag (C) is set to “1” if a carry is generated as a result of the calculation, or is cleared to “0” if a borrow is generated. To determine whether a calculation has generated a carry, the C flag must be initialized to “0” before each calculation. To check for a borrow, the C flag must be initialized to “1” before each calculation.

**Fig. 3.3.9 Status flag at decimal calculations**

**(3) JMP instruction**

When using the **JMP** instruction in indirect addressing mode, do not specify the last address on a page as an indirect address.

# APPENDIX

## 3.3 Notes on use

---

### 3.3.13 Notes on CPU reprogramming mode

- (1) Transfer the CPU reprogramming mode control program to the internal RAM before selecting the CPU reprogramming mode, and then, execute it on the internal RAM. Additionally, when the subroutine or stack operation instruction is used in the control program, make sure in order not to destroy the control program transferred to the internal RAM through the stack area.
- (2) Be careful of the instruction description (specifying address, and so on) because the CPU reprogramming mode control program is transferred to the internal RAM and executed on the internal RAM.
- (3) Write to the watchdog timer control register periodically in order not to generate the watchdog timer interrupt by the CPU reprogramming mode control program (refer to “**2.9 Watchdog timer**”).

### 3.3.14 Notes on flash memory version

The CNV<sub>SS</sub> pin is connected to the internal memory circuit block by a low-ohmic resistance, since it has the multiplexed function to be a programmable power source pin (V<sub>PP</sub> pin) as well.

To improve the noise margin, connect the CNV<sub>SS</sub> pin to V<sub>SS</sub> through 1 to 10 kΩ resistance.

Even when the wiring of the CNV<sub>SS</sub> pin of the mask ROM version is connected to V<sub>SS</sub> through this resistor, that will not affect operation.

### 3.3.15 Termination of unused pins

#### (1) Terminate unused pins

① Output ports : Open

② Input ports :

Connect each pin to VCC or VSS through each resistor of 1 k $\Omega$  to 10 k $\Omega$ .

As for pins whose potential affects to operation modes such as pin INT or others, select the VCC pin or the VSS pin according to their operation mode.

③ I/O ports :

- Set the I/O ports for the input mode and connect them to VCC or VSS through each resistor of 1 k $\Omega$  to 10 k $\Omega$ .

Ports that permit the selecting of a built-in pull-up resistor can also use this resistor. Set the I/O ports for the output mode and open them at "L" or "H".

- When opening them in the output mode, the input mode of the initial status remains until the mode of the ports is switched over to the output mode by the program after reset. Thus, the potential at these pins is undefined and the power source current may increase in the input mode. With regard to an effects on the system, thoroughly perform system evaluation on the user side.
- Since the direction register setup may be changed because of a program runaway or noise, set direction registers by program periodically to increase the reliability of program.

#### (2) Termination remarks

① Input ports and I/O ports :

Do not open in the input mode.

● Reason

- The power source current may increase depending on the first-stage circuit.
- An effect due to noise may be easily produced as compared with proper termination ② and ③ shown on the above.

② I/O ports :

When setting for the input mode, do not connect to VCC or VSS directly.

● Reason

If the direction register setup changes for the output mode because of a program runaway or noise, a short circuit may occur between a port and VCC (or VSS).

③ I/O ports :

When setting for the input mode, do not connect multiple ports in a lump to VCC or VSS through a resistor.

● Reason

If the direction register setup changes for the output mode because of a program runaway or noise, a short circuit may occur between ports.

- At the termination of unused pins, perform wiring at the shortest possible distance (20 mm or less) from microcomputer pins.

# APPENDIX

## 3.4 Countermeasures against noise

### 3.4 Countermeasures against noise

Countermeasures against noise are described below. The following countermeasures are effective against noise in theory, however, it is necessary not only to take measures as follows but to evaluate before actual use.

#### 3.4.1 Shortest wiring length

The wiring on a printed circuit board can function as an antenna which feeds noise into the microcomputer. The shorter the total wiring length (by mm unit), the less the possibility of noise insertion into a microcomputer.

##### (1) Wiring for $\overline{\text{RESET}}$ pin

Make the length of wiring which is connected to the  $\overline{\text{RESET}}$  pin as short as possible. Especially, connect a capacitor across the  $\overline{\text{RESET}}$  pin and the  $V_{\text{SS}}$  pin with the shortest possible wiring (within 20 mm).

##### ● Reason

The width of a pulse input into the  $\overline{\text{RESET}}$  pin is determined by the timing necessary conditions. If noise having a shorter pulse width than the standard is input to the  $\overline{\text{RESET}}$  pin, the reset is released before the internal state of the microcomputer is completely initialized. This may cause a program runaway.

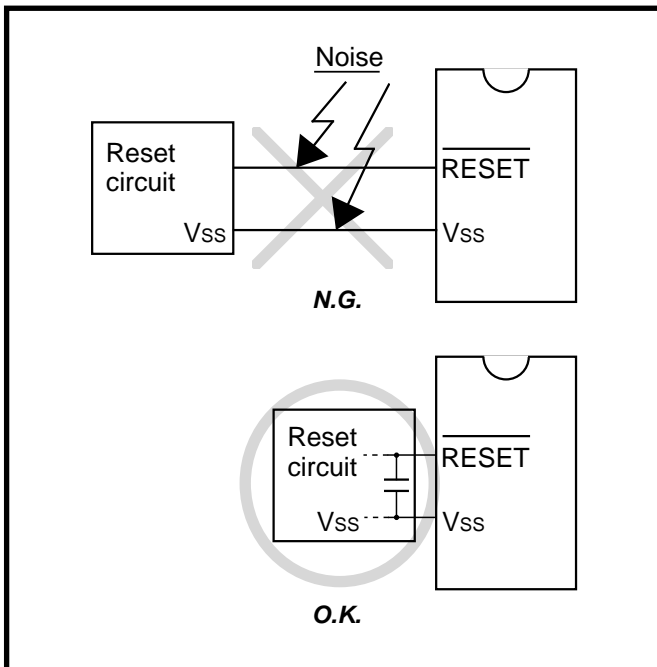

Fig. 3.4.1 Wiring for the  $\overline{\text{RESET}}$  pin

### (2) Wiring for clock input/output pins

- Make the length of wiring which is connected to clock I/O pins as short as possible.
- Make the length of wiring (within 20 mm) across the grounding lead of a capacitor which is connected to an oscillator and the Vss pin of a microcomputer as short as possible.
- Separate the Vss pattern only for oscillation from other Vss patterns.

#### ● Reason

If noise enters clock I/O pins, clock waveforms may be deformed. This may cause a program failure or program runaway. Also, if a potential difference is caused by the noise between the Vss level of a microcomputer and the Vss level of an oscillator, the correct clock will not be input in the microcomputer.

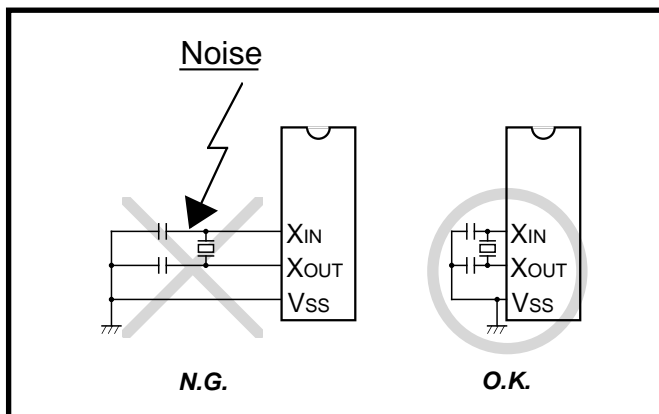

Fig. 3.4.2 Wiring for clock I/O pins

### (3) Wiring to CNVss pin

Connect the CNVss pin to the Vss pin with the shortest possible wiring.

#### ● Reason

The processor mode of a microcomputer is influenced by a potential at the CNVss pin. If a potential difference is caused by the noise between pins CNVss and Vss, the processor mode may become unstable. This may cause a microcomputer malfunction or a program runaway.

Fig. 3.4.3 Wiring for CNVss pin

# APPENDIX

## 3.4 Countermeasures against noise

### (4) Wiring to VPP pin of flash memory version

Connect an approximately 5 kΩ resistor to the VPP pin the shortest possible in series and also to the Vss pin. When not connecting the resistor, make the length of wiring between the VPP pin and the Vss pin the shortest possible.

**Note:** Even when a circuit which included an approximately 5 kΩ resistor is used in the Mask ROM version, the microcomputer operates correctly.

#### ● Reason

The VPP pin of the flash memory version is the power source input pin for the built-in flash memory. When programming/erasing in the built-in flash memory, the impedance of the VPP pin is low to allow the electric current for writing/erasing flow into the flash memory. Because of this, noise can enter easily. If noise enters the VPP pin, abnormal instruction codes or data are read from the built-in flash memory, which may cause a program runaway.

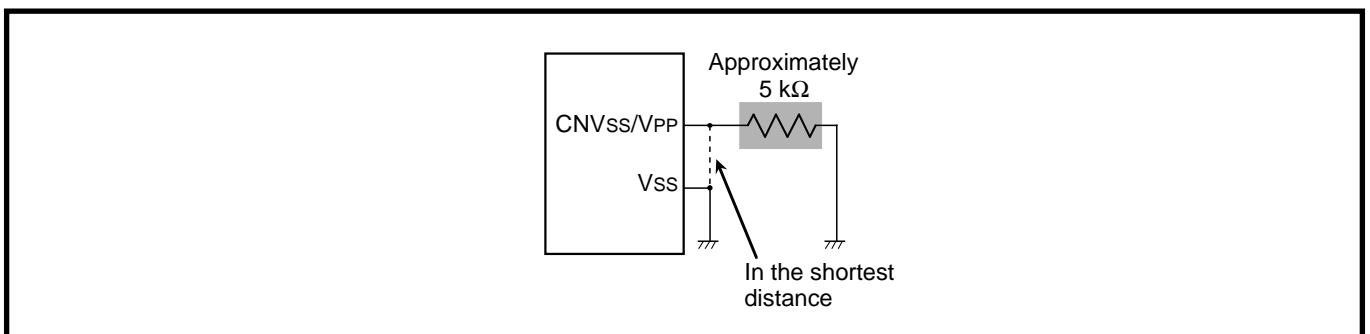

Fig. 3.4.4 Wiring for the VPP pin of the flash memory version

### 3.4.2 Connection of bypass capacitor across Vss line and Vcc line

Connect an approximately 0.1 μF bypass capacitor across the Vss line and the Vcc line as follows:

- Connect a bypass capacitor across the Vss pin and the Vcc pin at equal length.
- Connect a bypass capacitor across the Vss pin and the Vcc pin with the shortest possible wiring.
- Use lines with a larger diameter than other signal lines for Vss line and Vcc line.
- Connect the power source wiring via a bypass capacitor to the Vss pin and the Vcc pin.

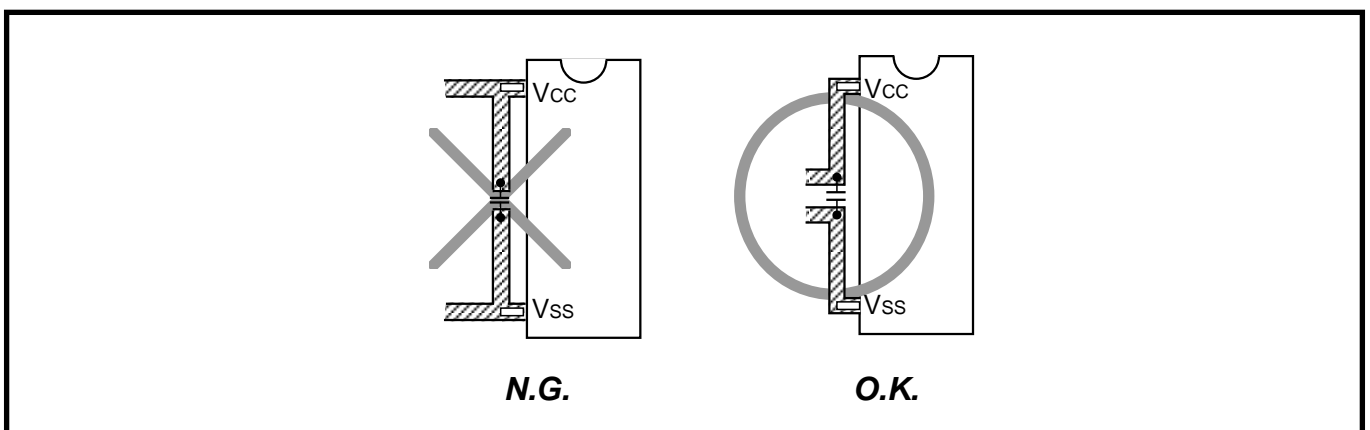

Fig. 3.4.5 Bypass capacitor across the Vss line and the Vcc line

### 3.4.3 Wiring to analog input pins

- Connect an approximately  $100\ \Omega$  to  $1\ \text{k}\Omega$  resistor to an analog signal line which is connected to an analog input pin in series. Besides, connect the resistor to the microcomputer as close as possible.
- Connect an approximately  $1000\ \text{pF}$  capacitor across the  $V_{SS}$  pin and the analog input pin. Besides, connect the capacitor to the  $V_{SS}$  pin as close as possible. Also, connect the capacitor across the analog input pin and the  $V_{SS}$  pin at equal length.

#### ● Reason

Signals which is input in an analog input pin (such as an A-D converter/comparator input pin) are usually output signals from sensor. The sensor which detects a change of event is installed far from the printed circuit board with a microcomputer, the wiring to an analog input pin is longer necessarily. This long wiring functions as an antenna which feeds noise into the microcomputer, which causes noise to an analog input pin.

If a capacitor between an analog input pin and the  $V_{SS}$  pin is grounded at a position far away from the  $V_{SS}$  pin, noise on the GND line may enter a microcomputer through the capacitor.

Fig. 3.4.6 Analog signal line and a resistor and a capacitor

# APPENDIX

## 3.4 Countermeasures against noise

### 3.4.4 Oscillator concerns

Take care to prevent an oscillator that generates clocks for a microcomputer operation from being affected by other signals.

#### (1) Keeping oscillator away from large current signal lines

Install a microcomputer (and especially an oscillator) as far as possible from signal lines where a current larger than the tolerance of current value flows.

● Reason

In the system using a microcomputer, there are signal lines for controlling motors, LEDs, and thermal heads or others. When a large current flows through those signal lines, strong noise occurs because of mutual inductance.

Fig. 3.4.7 Wiring for a large current signal line

#### (2) Installing oscillator away from signal lines where potential levels change frequently

Install an oscillator and a connecting pattern of an oscillator away from signal lines where potential levels change frequently. Also, do not cross such signal lines over the clock lines or the signal lines which are sensitive to noise.

● Reason

Signal lines where potential levels change frequently (such as the CNTR pin signal line) may affect other lines at signal rising edge or falling edge. If such lines cross over a clock line, clock waveforms may be deformed, which causes a microcomputer failure or a program runaway.

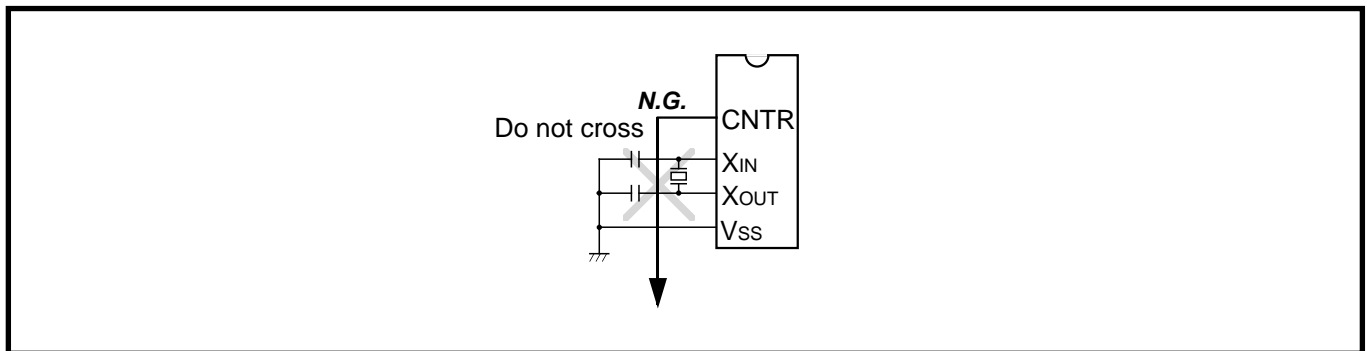

Fig. 3.4.8 Wiring of signal lines where potential levels change frequently

### (3) Oscillator protection using Vss pattern

As for a two-sided printed circuit board, print a Vss pattern on the underside (soldering side) of the position (on the component side) where an oscillator is mounted.

Connect the Vss pattern to the microcomputer Vss pin with the shortest possible wiring. Besides, separate this Vss pattern from other Vss patterns.

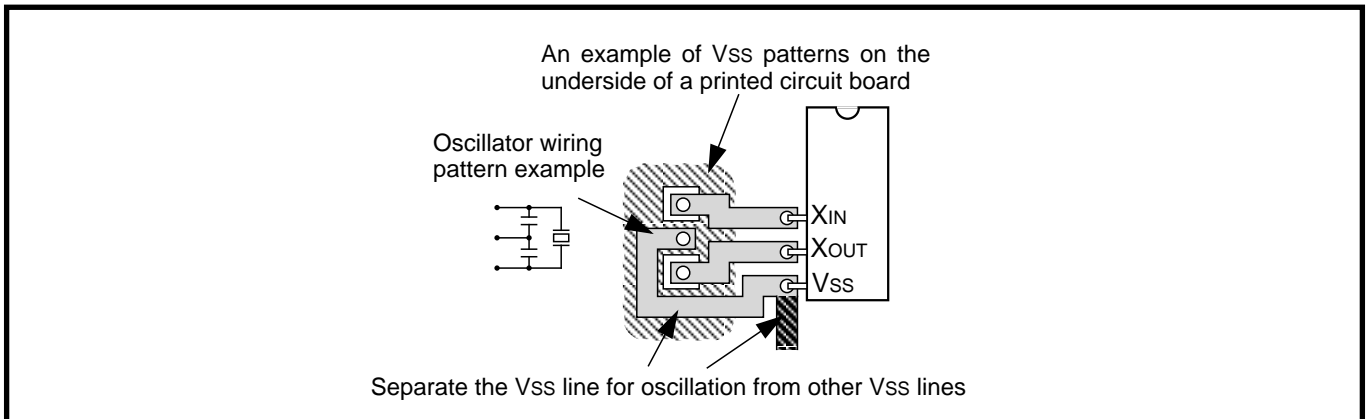

Fig. 3.4.9 Vss pattern on the underside of an oscillator

### 3.4.5 Setup for I/O ports

Setup I/O ports using hardware and software as follows:

#### <Hardware>

- Connect a resistor of 100  $\Omega$  or more to an I/O port in series.

#### <Software>

- As for an input port, read data several times by a program for checking whether input levels are equal or not.
- As for an output port, since the output data may reverse because of noise, rewrite data to its port latch at fixed periods.
- Rewrite data to direction registers and pull-up control registers at fixed periods.

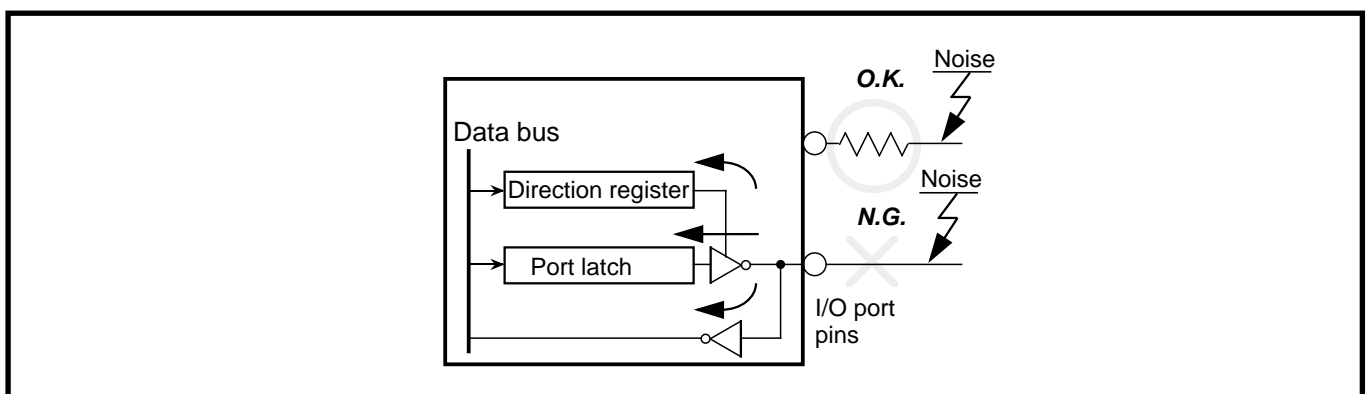

Fig. 3.4.10 Setup for I/O ports

# APPENDIX

## 3.4 Countermeasures against noise

### 3.4.6 Providing of watchdog timer function by software

If a microcomputer runs away because of noise or others, it can be detected by a software watchdog timer and the microcomputer can be reset to normal operation. This is equal to or more effective than program runaway detection by a hardware watchdog timer. The following shows an example of a watchdog timer provided by software.

In the following example, to reset a microcomputer to normal operation, the main routine detects errors of the interrupt processing routine and the interrupt processing routine detects errors of the main routine. This example assumes that interrupt processing is repeated multiple times in a single main routine processing.

#### <The main routine>

- Assigns a single byte of RAM to a software watchdog timer (SWDT) and writes the initial value N in the SWDT once at each execution of the main routine. The initial value N should satisfy the following condition:  
 $N+1 \geq (\text{Counts of interrupt processing executed in each main routine})$   
As the main routine execution cycle may change because of an interrupt processing or others, the initial value N should have a margin.
- Watches the operation of the interrupt processing routine by comparing the SWDT contents with counts of interrupt processing after the initial value N has been set.
- Detects that the interrupt processing routine has failed and determines to branch to the program initialization routine for recovery processing in the following case:  
If the SWDT contents do not change after interrupt processing.

#### <The interrupt processing routine>

- Decrements the SWDT contents by 1 at each interrupt processing.
- Determines that the main routine operates normally when the SWDT contents are reset to the initial value N at almost fixed cycles (at the fixed interrupt processing count).
- Detects that the main routine has failed and determines to branch to the program initialization routine for recovery processing in the following case:  
If the SWDT contents are not initialized to the initial value N but continued to decrement and if they reach 0 or less.

## 3.7 Machine instructions

### 3.7 Machine instructions

Symbol	Function	Details	Addressing mode																				
			IMP			IMM			A			BIT, A, R			ZP			BIT, ZP, R					
			OP	n	#	OP	n	#	OP	n	#	OP	n	#	OP	n	#	OP	n	#			
ADC (Note 1) (Note 5)	When T = 0 $A \leftarrow A + M + C$  When T = 1 $M(X) \leftarrow M(X) + M + C$	When T = 0, this instruction adds the contents M, C, and A; and stores the results in A and C. When T = 1, this instruction adds the contents of M(X), M and C; and stores the results in M(X) and C. When T=1, the contents of A remain unchanged, but the contents of status flags are changed. M(X) represents the contents of memory where is indicated by X.				69	2	2										65	3	2			
AND (Note 1)	When T = 0 $A \leftarrow A \wedge M$  When T = 1 $M(X) \leftarrow M(X) \wedge M$	When T = 0, this instruction transfers the contents of A and M to the ALU which performs a bit-wise AND operation and stores the result back in A. When T = 1, this instruction transfers the contents M(X) and M to the ALU which performs a bit-wise AND operation and stores the results back in M(X). When T = 1, the contents of A remain unchanged, but status flags are changed. M(X) represents the contents of memory where is indicated by X.				29	2	2										25	3	2			
ASL		This instruction shifts the content of A or M by one bit to the left, with bit 0 always being set to 0 and bit 7 of A or M always being contained in C.							0A	2	1							06	5	2			
BBC (Note 4)	$A_i$ or $M_i = 0?$	This instruction tests the designated bit i of M or A and takes a branch if the bit is 0. The branch address is specified by a relative address. If the bit is 1, next instruction is executed.										$13$ $\downarrow$ $20i$	4	2				$17$ $\downarrow$ $20i$	5	3			
BBS (Note 4)	$A_i$ or $M_i = 1?$	This instruction tests the designated bit i of the M or A and takes a branch if the bit is 1. The branch address is specified by a relative address. If the bit is 0, next instruction is executed.										$03$ $\downarrow$ $20i$	4	2				$07$ $\downarrow$ $20i$	5	3			
BCC (Note 4)	$C = 0?$	This instruction takes a branch to the appointed address if C is 0. The branch address is specified by a relative address. If C is 1, the next instruction is executed.																					
BCS (Note 4)	$C = 1?$	This instruction takes a branch to the appointed address if C is 1. The branch address is specified by a relative address. If C is 0, the next instruction is executed.																					
BEQ (Note 4)	$Z = 1?$	This instruction takes a branch to the appointed address when Z is 1. The branch address is specified by a relative address. If Z is 0, the next instruction is executed.																					
BIT	$A \wedge M$	This instruction takes a bit-wise logical AND of A and M contents; however, the contents of A and M are not modified. The contents of N, V, Z are changed, but the contents of A, M remain unchanged.																24	3	2			
BMI (Note 4)	$N = 1?$	This instruction takes a branch to the appointed address when N is 1. The branch address is specified by a relative address. If N is 0, the next instruction is executed.																					
BNE (Note 4)	$Z = 0?$	This instruction takes a branch to the appointed address if Z is 0. The branch address is specified by a relative address. If Z is 1, the next instruction is executed.

JMP	If addressing mode is ABS $PCL \leftarrow ADL$ $PCH \leftarrow ADH$ If addressing mode is IND $PCL \leftarrow M(ADH, ADL)$ $PCH \leftarrow M(ADH, ADL + 1)$ If addressing mode is ZP, IND $PCL \leftarrow M(00, ADL)$ $PCH \leftarrow M(00, ADL + 1)$	This instruction jumps to the address designated by the following three addressing modes: Absolute Indirect Absolute Zero Page Indirect Absolute																		
JSR	$M(S) \leftarrow PCH$ $S \leftarrow S - 1$ $M(S) \leftarrow PCL$ $S \leftarrow S - 1$ After executing the above, if addressing mode is ABS, $PCL \leftarrow ADL$ $PCH \leftarrow ADH$ if addressing mode is SP, $PCL \leftarrow ADL$ $PCH \leftarrow FF$ If addressing mode is ZP, IND, $PCL \leftarrow M(00, ADL)$ $PCH \leftarrow M(00, ADL + 1)$	This instruction stores the contents of the PC in the stack, then jumps to the address designated by the following addressing modes: Absolute Special Page Zero Page Indirect Absolute																		
LDA (Note 2)	When T = 0 $A \leftarrow M$ When T = 1 $M(X) \leftarrow M$	When T = 0, this instruction transfers the contents of M to A. When T = 1, this instruction transfers the contents of M to M(X). The contents of A remain unchanged, but status flags are changed. M(X) represents the contents of memory where is indicated by X.				A9	2	2							A5	3	2			
LDM	$M \leftarrow nn$	This instruction loads the immediate value in M.													3C	4	3			
LDX	$X \leftarrow M$	This instruction loads the contents of M in X.				A2	2	2							A6	3	2			
LDY	$Y \leftarrow M$	This instruction loads the contents of M in Y.				A0	2	2							A4	3	2			

# APPENDIX

## 3.7 Machine instructions

Symbol	Function	Details	Addressing mode																			
			IMP			IMM			A			BIT, A			ZP			BIT, ZP				
			OP	n	#	OP	n	#	OP	n	#	OP	n	#	OP	n	#	OP	n	#		
LSR	$0 \rightarrow \begin{array}{ c } \hline 7 \quad 0 \\ \hline \end{array} \rightarrow \text{C}$	This instruction shifts either A or M one bit to the right such that bit 7 of the result always is set to 0, and the bit 0 is stored in C.								4A	2	1					46	5	2			
MUL	$M(S) \cdot A \leftarrow A * M(zz + X)$ $S \leftarrow S - 1$	This instruction multiply Accumulator with the memory specified by the Zero Page X address mode and stores the high-order byte of the result on the Stack and the low-order byte in A.																				
NOP	$PC \leftarrow PC + 1$	This instruction adds one to the PC but does no other operation.	EA	2	1																	
ORA (Note 1)	When T = 0 $A \leftarrow A \vee M$  When T = 1 $M(X) \leftarrow M(X) \vee M$	When T = 0, this instruction transfers the contents of A and M to the ALU which performs a bit-wise "OR", and stores the result in A. When T = 1, this instruction transfers the contents of M(X) and the M to the ALU which performs a bit-wise OR, and stores the result in M(X). The contents of A remain unchanged, but status flags are changed. M(X) represents the contents of memory where is indicated by X.				09	2	2									05	3	2			
PHA	$M(S) \leftarrow A$ $S \leftarrow S - 1$	This instruction pushes the contents of A to the memory location designated by S, and decrements the contents of S by one.	48	3	1																	
PHP	$M(S) \leftarrow PS$ $S \leftarrow S - 1$	This instruction pushes the contents of PS to the memory location designated by S and decrements the contents of S by one.	08	3	1																	
PLA	$S \leftarrow S + 1$ $A \leftarrow M(S)$	This instruction increments S by one and stores the contents of the memory designated by S in A.	68	4	1																	
PLP	$S \leftarrow S + 1$ $PS \leftarrow M(S)$	This instruction increments S by one and stores the contents of the memory location designated by S in PS.	28	4	1																	
ROL	$\begin{array}{ c } \hline 7 \quad 0 \\ \hline \end{array} \leftarrow \text{C}$	This instruction shifts either A or M one bit left through C. C is stored in bit 0 and bit 7 is stored in C.								2A	2	1					26	5	2			
ROR	$\text{C} \rightarrow \begin{array}{ c } \hline 7 \quad 0 \\ \hline \end{array}$	This instruction shifts either A or M one bit right through C. C is stored in bit 7 and bit 0 is stored in C.								6A	2	1					66	5	2			
RRF	$\begin{array}{ c } \hline 7 \quad 0 \\ \hline \end{array} \rightarrow$	This instruction rotates 4 bits of the M content to the right.															82	8	2			
RTI	$S \leftarrow S + 1$ $PS \leftarrow M(S)$ $S \leftarrow S + 1$ $PCL \leftarrow M(S)$ $S \leftarrow S + 1$ $PCH \leftarrow M(S)$	This instruction increments S by one, and stores the contents of the memory location designated by S in PS. S is again incremented by one and stores the contents of the memory location designated by S in PCL. S is again incremented by one and stores the contents of memory location designated by S in PCH.	40	6	1																	
RTS	$S \leftarrow S + 1$ $PCL \leftarrow M(S)$ $S \leftarrow S + 1$ $PCH \leftarrow M(S)$ $(PC) \leftarrow (PC) + 1$	This instruction increments S by one and stores the contents of the memory location designated by S in PCL. S is again incremented by one and the contents of the memory location is stored in PCH. PC is incremented by 1.	60	6	1

			IMP			IMM			A			BIT, A			ZP			BIT, ZP					
			OP	n	#	OP	n	#	OP	n	#	OP	n	#	OP	n	#	OP	n	#			
SBC (Note 1) (Note 5)	When T = 0 $A \leftarrow A - M - \bar{C}$ When T = 1 $M(X) \leftarrow M(X) - M - \bar{C}$	When T = 0, this instruction subtracts the value of M and the complement of C from A, and stores the results in A and C. When T = 1, the instruction subtracts the contents of M and the complement of C from the contents of M(X), and stores the results in M(X) and C. A remain unchanged, but status flag are changed. M(X) represents the contents of memory where is indicated by X.				E9	2	2										E5	3	2			
SEB	$A_i$ or $M_i \leftarrow 1$	This instruction sets the designated bit i of A or M.										0F 20i	2	1				0F 20i	5	2			
SEC	$C \leftarrow 1$	This instruction sets C.	38	2	1																		
SED	$D \leftarrow 1$	This instruction set D.	F8	2	1																		
SEI	$I \leftarrow 1$	This instruction set I.	78	2	1																		
SET	$T \leftarrow 1$	This instruction set T.	32	2	1																		
STA	$M \leftarrow A$	This instruction stores the contents of A in M. The contents of A does not change.																85	4	2			
STP		This instruction resets the oscillation control F/F and the oscillation stops. Reset or interrupt input is needed to wake up from this mode.	42	2	1																		
STX	$M \leftarrow X$	This instruction stores the contents of X in M. The contents of X does not change.																86	4	2			
STY	$M \leftarrow Y$	This instruction stores the contents of Y in M. The contents of Y does not change.																84	4	2			
TAX	$X \leftarrow A$	This instruction stores the contents of A in X. The contents of A does not change.	AA	2	1																		
TAY	$Y \leftarrow A$	This instruction stores the contents of A in Y. The contents of A does not change.	A8	2	1																		
TST	$M = 0?$	This instruction tests whether the contents of M are "0" or not and modifies the N and Z.																64	3	2			
TSX	$X \leftarrow S$	This instruction transfers the contents of S in X.	BA	2	1																		
TXA	$A \leftarrow X$	This instruction stores the contents of X in A.	8A	2	1																		
TXS	$S \leftarrow X$	This instruction stores the contents of X in S.	9A	2	1																		
TYA	$A \leftarrow Y$	This instruction stores the contents of Y in A.	98	2	1																		
WIT		The WIT instruction stops the internal clock but not the oscillation of the oscillation circuit is not stopped. CPU starts its function after the Timer X over flows (comes to the terminal count). All registers or internal memory contents except Timer X will not change during this mode. (Of course needs VDD).	C2	2	1																		

- Notes 1 : The number of cycles "n" is increased by 3 when T is 1.  
 2 : The number of cycles "n" is increased by 2 when T is 1.  
 3 : The number of cycles "n" is increased by 1 when T is 1.  
 4 : The number of cycles "n" is increased by 2 when branching has occurred.  
 5 : N, V, and Z flags are invalid in decimal operation mode.

## 3.7 Machine instructions

Symbol	Contents	Symbol	Contents
IMP	Implied addressing mode	+	Addition
IMM	Immediate addressing mode	-	Subtraction
A	Accumulator or Accumulator addressing mode	*	Multiplication
BIT, A	Accumulator bit addressing mode	/	Division
BIT, A, R	Accumulator bit relative addressing mode	∧	Logical OR
ZP	Zero page addressing mode	∨	Logical AND
BIT, ZP	Zero page bit addressing mode	⊕	Logical exclusive OR
BIT, ZP, R	Zero page bit relative addressing mode	—	Negation
ZP, X	Zero page X addressing mode	←	Shows direction of data flow
ZP, Y	Zero page Y addressing mode	X	Index register X
ABS	Absolute addressing mode	Y	Index register Y
ABS, X	Absolute X addressing mode	S	Stack pointer
ABS, Y	Absolute Y addressing mode	PC	Program counter
IND	Indirect absolute addressing mode	PS	Processor status register
		PCH	8 high-order bits of program counter
ZP, IND	Zero page indirect absolute addressing mode	PCL	8 low-order bits of program counter
		ADH	8 high-order bits of address
IND, X	Indirect X addressing mode	ADL	8 low-order bits of address
IND, Y	Indirect Y addressing mode	FF	FF in Hexadecimal notation
REL	Relative addressing mode	nn	Immediate value
SP	Special page addressing mode	zz	Zero page address
C	Carry flag	M	Memory specified by address designation of any addressing mode
Z	Zero flag	M(X)	Memory of address indicated by contents of index register X
I	Interrupt disable flag	M(S)	Memory of address indicated by contents of stack pointer
D	Decimal mode flag	M(ADH, ADL)	Contents of memory at address indicated by ADH and ADL, in ADH is 8 high-order bits and ADL is 8 low-order bits.
B	Break flag	M(00, ADL)	Contents of address indicated by zero page ADL
T	X-modified arithmetic mode flag	Ai	Bit i (i = 0 to 7) of accumulator
V	Overflow flag	Mi	Bit i (i = 0 to 7) of memory
N	Negative flag	OP	Opcode
		n	Number of cycles
		#	Number of bytes

## 3.9 M35501FP

### 3.9 M35501FP

#### DESCRIPTION

The M35501FP generates digit signals for fluorescent display when connected to the output port of a microcomputer. There are up to 16 digit pins available, and more can be added by connecting additional M35501FPs. The number of fluorescent displays can be increased easily by connecting the M35501FP to the CMOS FLD output pins of an 8-bit microcomputer in MITSUBISHI's 38B7 Group. The M35501FP is suitable for fluorescent display control on household electric appliances, audio products, etc.

#### FEATURES

- Digit output ..... 16 (maximum)
  - Up to 16 pins can be selected
  - More digits available by connecting additional M35501FPs
  - Output structure: high-breakdown voltage, P-channel open-drain; built-in pull-down resistor between digit output pins and VEE pin
- Power-on reset circuit ..... Built-in
- Power source voltage ..... 4.0 to 5.5 V
- Pull-down power source voltage .....  $V_{CC} - 43\text{ V}$
- Operating temperature range .....  $-20\text{ to }85\text{ }^{\circ}\text{C}$
- Package ..... 24P2E
- Power dissipation .....  $250\text{ }\mu\text{W}$  (at 100 kHz operation clock)

#### PIN CONFIGURATION (TOP VIEW)

**Outline: 24P2E-A**  
**24-pin plastic-molded SSOP**

Fig. 3.9.1 Pin configuration of M35501FP

### FUNCTIONAL BLOCK

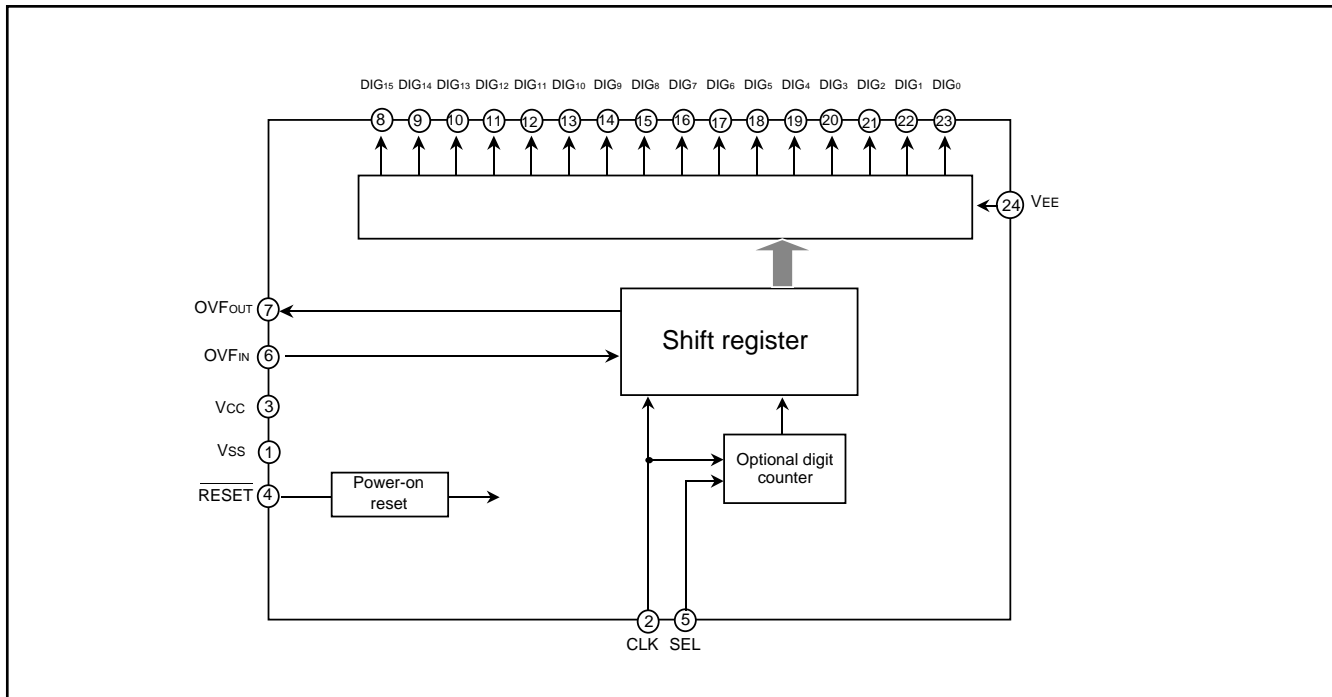

Fig. 3.9.2 Functional block diagram

### PIN DESCRIPTION

Table 3.9.1 Pin description

Pin	Name	Function	Output Structure	Fig. No.
VCC, VSS	Power source input	Apply 4.0–5.5 V to VCC, and 0V to VSS.	–	–
RESET	Reset input	Reset internal shift register (built-in power-on reset circuit).	CMOS input level Built-in pull-up resistor	3
CLK	Clock input	Digit output varies according to rising edge of clock input.	CMOS input level Built-in pull-down resistor	2
SEL	Select input	Use when specifying the number of digits.	CMOS input level Built-in pull-down resistor	2
OVFIN	Overflow signal input	Input "H" when using one M35501FP. Connect to OVFOUT pin of additional M35501FPs when using multiple M35501FPs (to use 17 digits or more).	CMOS input level	4
OVFOUT	Overflow signal output	Leave open when using one M35501FP. Connect to OVFIN pin of additional M35501FPs when using multiple M35501FPs (to use 17 digits or more).	CMOS output	5
DIG15– DIG0	Digit output	Output the digit output waveform of fluorescent display. Leave open when not in use (VEE level output).	High-breakdown-voltage P-channel open-drain output Built-in pull-down resistor	1
VEE	Pull-down power source input	Apply voltage to DIG0–DIG15 pull-down resistors.	–	–

# APPENDIX

## 3.9 M35501FP

### PORT BLOCK

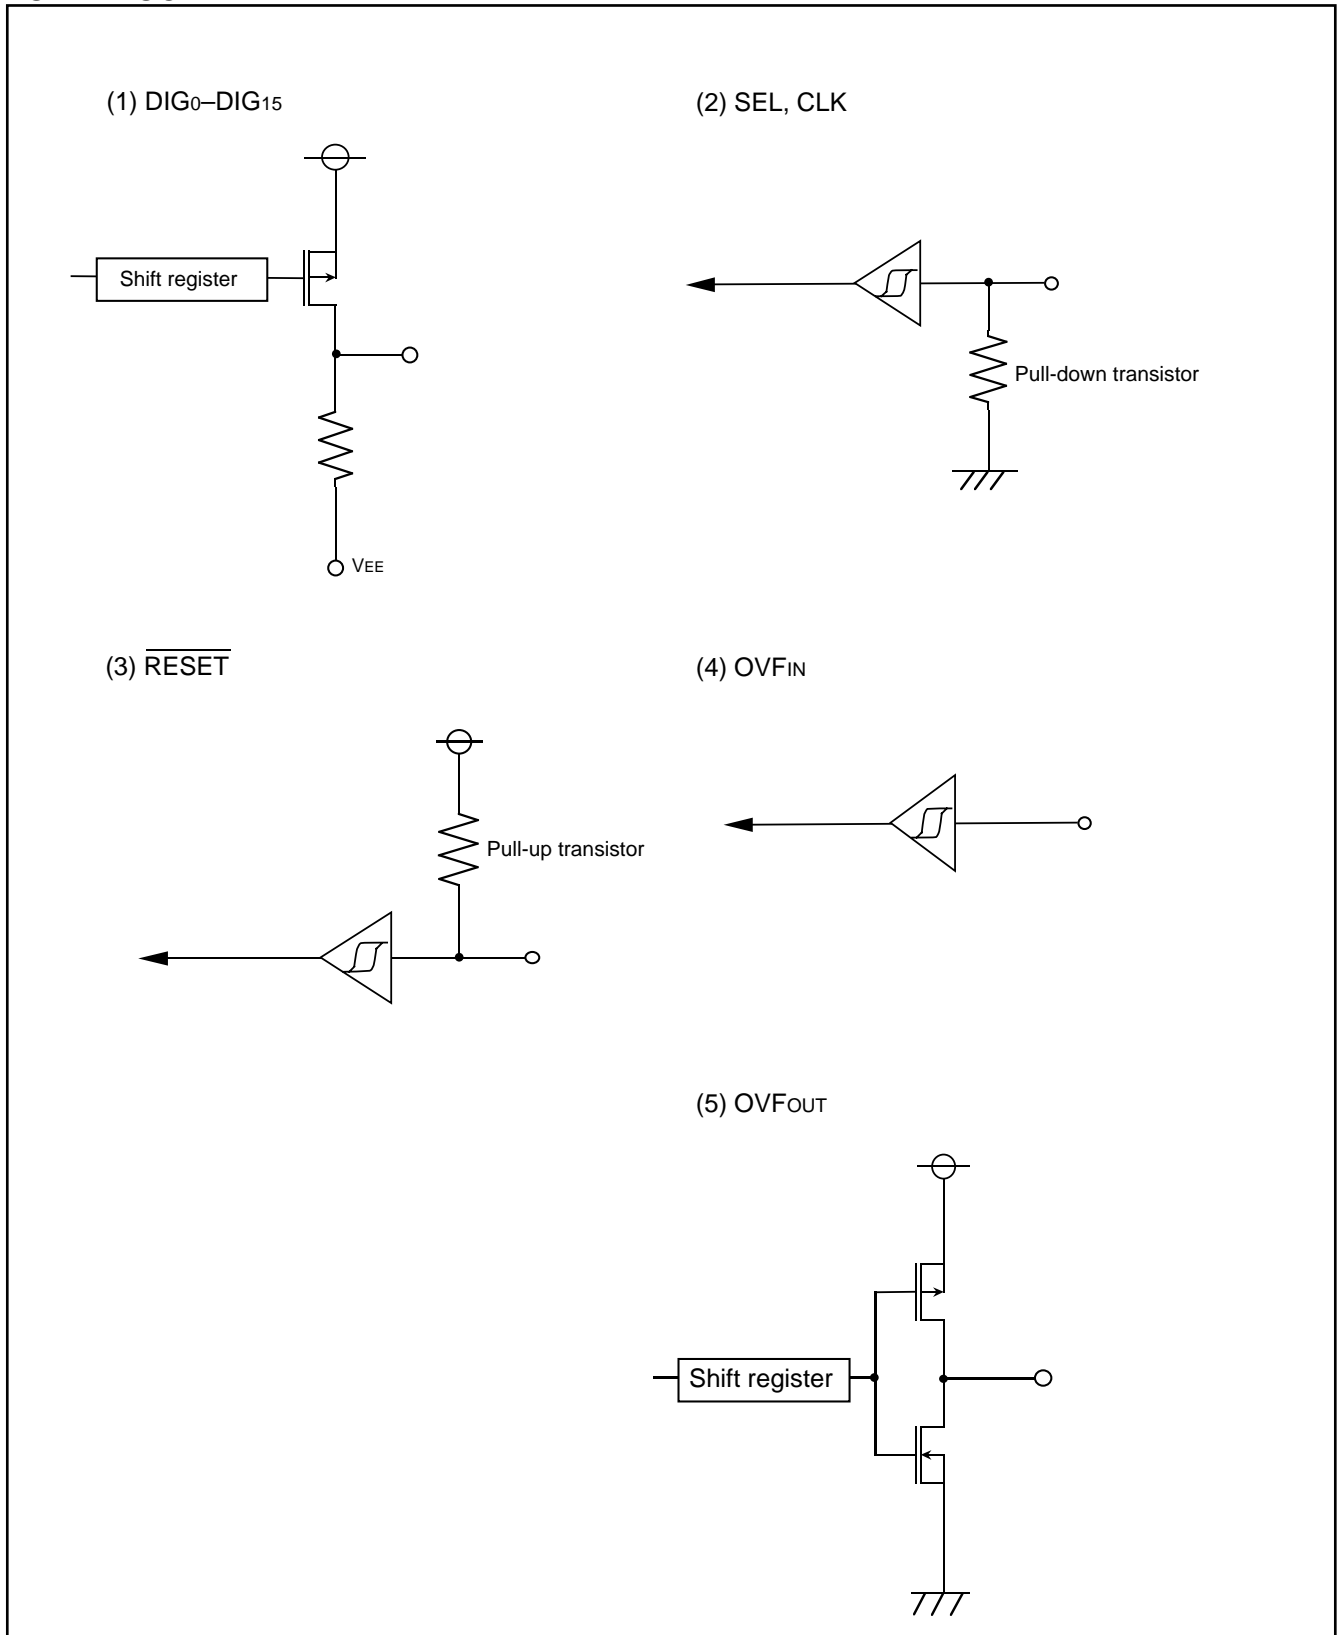

Fig. 3.9.3 Port block diagram

## USAGE

Three usages of the M35501FP are described below.

### (1) 16-Digit Mode: 16 digits selected

The number of digits is set to 16 by fixing the OVF<sub>IN</sub> pin to "H" and the SEL pin to "L." Figure 3.9.5 shows the output waveform.

### (2) Optional Digit Mode: 1-16 digits selectable

When the number of CLK pin rising edges during an "H" period of the SEL pin is  $n$  and the OVF<sub>IN</sub> pin is fixed to "H," the number of digits set is  $n$ . If  $n$  is 16 or more, all 16 digits are set. Figure 3.9.6 shows the output waveform.

Fig. 3.9.4 Digit setting

### (3) Cascade Mode: 17 digits or more selectable

17 digits or more can be used by connecting two M35501FPs or more. Figure 3.9.7 shows an example using three M35501FPs, offering 33 to 48 digit outputs.

Cascade mode will not operate if all M35501FPs are in 16-digit mode (SEL = "L"). Use the most significant M35501FP in the optional digit mode for DIG output. Figure 3.9.8 shows the output waveform.

# APPENDIX

## 3.9 M35501FP

### DIGIT OUTPUT WAVEFORM

Fig. 3.9.5 16-digit mode output waveform

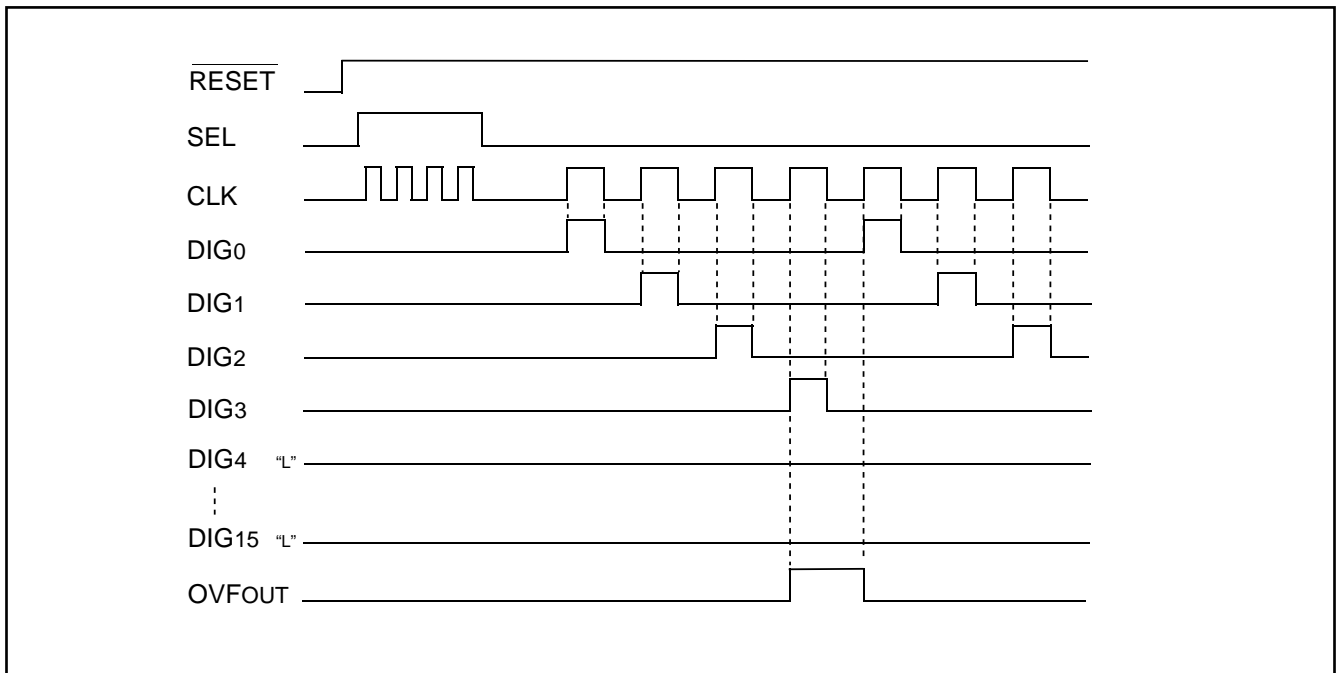

Fig. 3.9.6 Optional digit mode output waveform

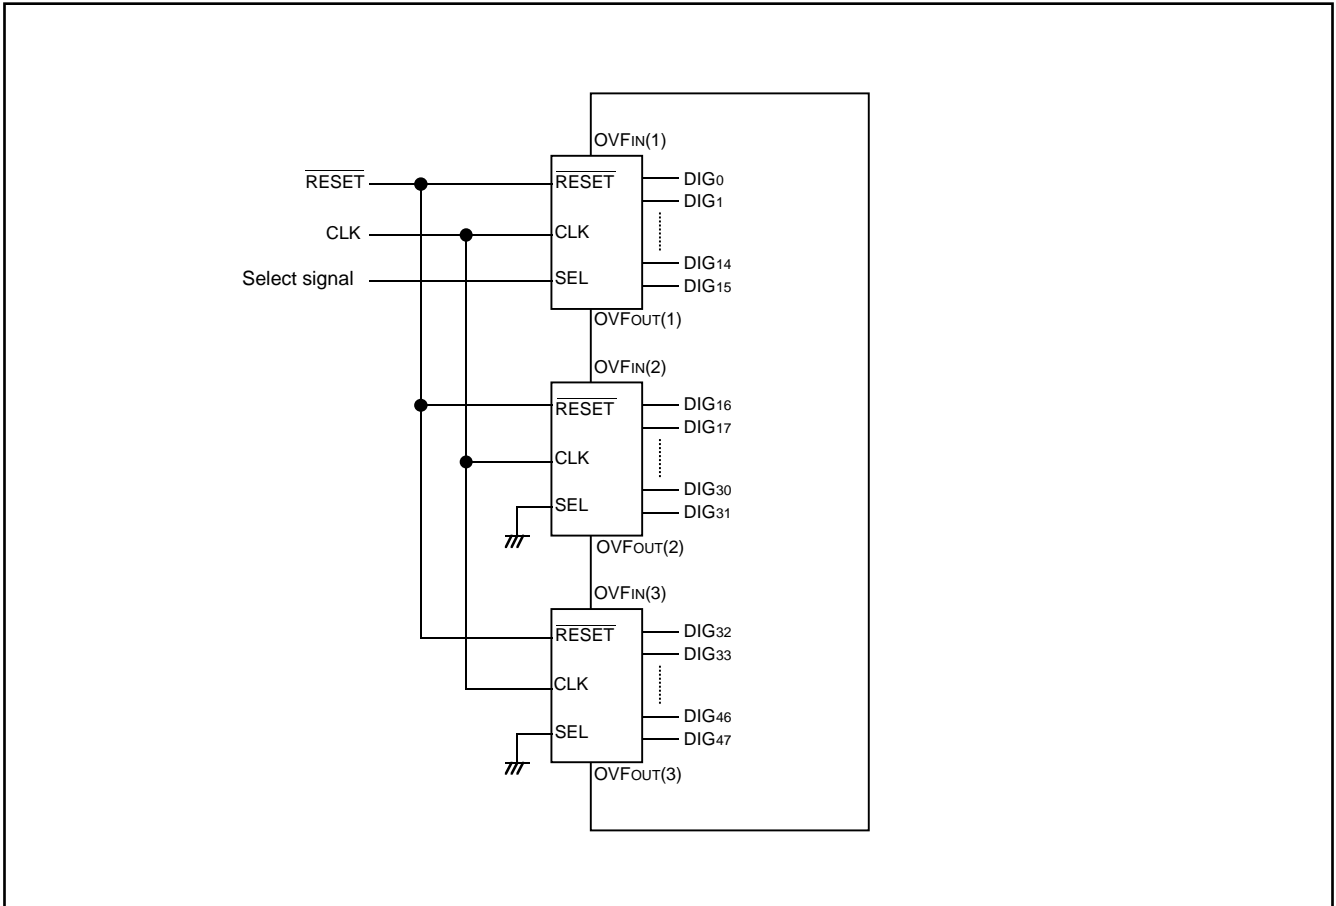

Fig. 3.9.7 Cascade mode connection example: 17 digits or more selected

Fig. 3.9.8 Cascade mode output waveform

# APPENDIX

## 3.9 M35501FP

The number of fluorescent displays can be increased by connecting the M35501FP to the CMOS FLD output pins on a 38B7 Group microcomputer.

Fig. 3.9.9 Connection example with 38B7 Group microcomputer (1 to 16 digits)

This FLD controller can control up to 32 digits using the 32 timing mode of the 38B7 Group microcomputer.

Fig. 3.9.10 Connection example with 38B7 Group microcomputer (17 to 32 digits)

### RESET CIRCUIT

To reset the controller, the  $\overline{\text{RESET}}$  pin should be held at "L" for 2  $\mu\text{s}$  or more. Reset is released when the  $\overline{\text{RESET}}$  pin is returned to "H" and the power source voltage is between 4.0 V and 5.5 V.

**Notes1:** Perform the reset release when CLK input signal is "L."

**2:** When setting the number of digits by SEL signal, optional digit counter is set to "0" by reset.

**Fig. 3.9.11** Digit output waveform when reset signal is input

# APPENDIX

## 3.9 M35501FP

### POWER-ON RESET

Reset can be performed automatically during power on (power-on reset) by the built-in power-on reset circuit. When using this circuit, set 100  $\mu$ s or less for the period in which it takes to reach minimum operation guaranteed voltage from reset.

If the rising time exceeds 100  $\mu$ s, connect the capacitor between the  $\overline{\text{RESET}}$  pin and  $V_{SS}$  at the shortest distance. Consequently, the  $\overline{\text{RESET}}$  pin should be held at "L" until the minimum operation guaranteed voltage is reached.

Fig. 3.9.12 Power-on reset circuit

**Table 3.9.2 Absolute maximum ratings**

Symbol	Parameter	Conditions	Ratings	Unit
VCC	Power source voltage	•All voltages are based on VSS. •Output transistors are off.	-0.3 to 7.0	V
VEE	Pull-down power source voltage		VCC -45 to VCC +0.3	V
VI	Input voltage CLK, SEL, OVFIN		-0.3 to VCC +0.3	V
VI	Input voltage $\overline{\text{RESET}}$		-0.3 to VCC +0.3	V
VO	Output voltage DIG0–DIG15		VCC -45 to VCC +0.3	V
VO	Output voltage OVFOUT		-0.3 to VCC +0.3	V
Pd	Power dissipation	Ta = 25 °C	250	mW
Topr	Operating temperature		-20 to 85	°C
Tstg	Storage temperature		-40 to 125	°C

**Table 3.9.3 Recommended operating conditions** (VCC = 4.0 to 5.5 V, Ta = -20 to 85 °C, unless otherwise noted)

Symbol	Parameter	Limits			Unit
		Min.	Typ.	Max.	
VCC	Power source voltage	4.0	5.0	5.5	V
VSS	Power source voltage		0		V
VEE	Pull-down power source voltage	VCC -43		VSS	V
VIH	“H” input voltage CLK, SEL, OVFIN	0.8VCC		VCC	V
VIH	“H” input voltage $\overline{\text{RESET}}$	0.8VCC		VCC	V
VIL	“L” input voltage CLK, SEL, OVFIN	0		0.2VCC	V
VIL	“L” input voltage $\overline{\text{RESET}}$	0		0.2VCC	V

**Table 3.9.4 Recommended operating conditions** (VCC = 4.0 to 5.5 V, Ta = -20 to 85 °C, unless otherwise noted)

Symbol	Parameter	Limits			Unit
		Min.	Typ.	Max.	
IOH(peak)	“H” peak output current DIG0 – DIG15 ( <b>Note 1</b> )			-36	mA
IOH(peak)	“H” peak output current OVFOUT ( <b>Note 1</b> )			-10	mA
IOL(peak)	“L” peak output current OVFOUT ( <b>Note 1</b> )			10	mA
IOH(avg)	“H” average current DIG0 – DIG15 ( <b>Note 2</b> )			-18	mA
IOH(avg)	“H” average current OVFOUT ( <b>Note 2</b> )			-5.0	mA
IOL(avg)	“L” average current OVFOUT ( <b>Note 2</b> )			5.0	mA
CLK	Clock input frequency			2	MHz

**Notes 1:** The peak output current is the peak current flowing in each port.

**2:** The average output current is an average value measured over 100 ms.

## 3.10 SFR memort map

### 3.10 SFR memory map

0000 <sub>16</sub>	Port P0 (P0)
0001 <sub>16</sub>	
0002 <sub>16</sub>	Port P1 (P1)
0003 <sub>16</sub>	Port P1 direction register (P1D)
0004 <sub>16</sub>	Port P2 (P2)
0005 <sub>16</sub>	
0006 <sub>16</sub>	Port P3 (P3)
0007 <sub>16</sub>	Port P3 direction register (P3D)
0008 <sub>16</sub>	Port P4 (P4)
0009 <sub>16</sub>	Port P4 direction register (P4D)
000A <sub>16</sub>	Port P5 (P5)
000B <sub>16</sub>	Port P5 direction register (P5D)
000C <sub>16</sub>	Port P6 (P6)
000D <sub>16</sub>	Port P6 direction register (P6D)
000E <sub>16</sub>	Port P7 (P7)
000F <sub>16</sub>	Port P7 direction register (P7D)
0010 <sub>16</sub>	Port P8 (P8)
0011 <sub>16</sub>	Port P8 direction register (P8D)
0012 <sub>16</sub>	Port P9 (P9)
0013 <sub>16</sub>	Port P9 direction register (P9D)
0014 <sub>16</sub>	Port PA (PA)
0015 <sub>16</sub>	Port PA direction register (PAD)
0016 <sub>16</sub>	Port PB (PB)
0017 <sub>16</sub>	Port PB direction register (PBD)
0018 <sub>16</sub>	Serial I/O1 automatic transfer data pointer (SIO1DP)
0019 <sub>16</sub>	Serial I/O1 control register 1 (SIO1CON1)
001A <sub>16</sub>	Serial I/O1 control register 2 (SIO1CON2)
001B <sub>16</sub>	Serial I/O1 register/Transfer counter (SIO1)
001C <sub>16</sub>	Serial I/O1 control register 3 (SIO1CON3)
001D <sub>16</sub>	Serial I/O2 control register (SIO2CON)
001E <sub>16</sub>	Serial I/O2 status register (SIO2STS)
001F <sub>16</sub>	Serial I/O2 transmit/receive buffer register (TB/RB)
0EEC <sub>16</sub>	Serial I/O3 control register (SIO3CON)
0EED <sub>16</sub>	Serial I/O3 register (SIO3)
0EEE <sub>16</sub>	Watchdog timer control register (WDTCON)
0EEF <sub>16</sub>	Pull-up control register 3 (PULL3)
0EF0 <sub>16</sub>	Pull-up control register 1 (PULL1)
0EF1 <sub>16</sub>	Pull-up control register 2 (PULL2)
0EF2 <sub>16</sub>	Port P0 digit output set switch register (P0DOR)
0EF3 <sub>16</sub>	Port P2 digit output set switch register (P2DOR)
0EF4 <sub>16</sub>	FLDC mode register (FLDM)
0EF5 <sub>16</sub>	Tdisp time set register (TDISP)

0020 <sub>16</sub>	Timer 1 (T1)
0021 <sub>16</sub>	Timer 2 (T2)
0022 <sub>16</sub>	Timer 3 (T3)
0023 <sub>16</sub>	Timer 4 (T4)
0024 <sub>16</sub>	Timer 5 (T5)
0025 <sub>16</sub>	Timer 6 (T6)
0026 <sub>16</sub>	PWM control register (PWMCON)
0027 <sub>16</sub>	Timer 6 PWM register (T6PWM)
0028 <sub>16</sub>	Timer 12 mode register (T12M)
0029 <sub>16</sub>	Timer 34 mode register (T34M)
002A <sub>16</sub>	Timer 56 mode register (T56M)
002B <sub>16</sub>	D-A conversion register (DA)
002C <sub>16</sub>	Timer X (low-order) (TXL)
002D <sub>16</sub>	Timer X (high-order) (TXH)
002E <sub>16</sub>	Timer X mode register 1 (TXM1)
002F <sub>16</sub>	Timer X mode register 2 (TXM2)
0030 <sub>16</sub>	Interrupt interval determination register (IID)
0031 <sub>16</sub>	Interrupt interval determination control register (IIDCON)
0032 <sub>16</sub>	AD/DA control register (ADCON)
0033 <sub>16</sub>	A-D conversion register (low-order) (ADL)
0034 <sub>16</sub>	A-D conversion register (high-order) (ADH)
0035 <sub>16</sub>	PWM register (high-order) (PWMH)
0036 <sub>16</sub>	PWM register (low-order) (PWML)
0037 <sub>16</sub>	Baud rate generator (BRG)
0038 <sub>16</sub>	UART control register (UARTCON)
0039 <sub>16</sub>	Interrupt source switch register (IFR)
003A <sub>16</sub>	Interrupt edge selection register (INTEDGE)
003B <sub>16</sub>	CPU mode register (CPUM)
003C <sub>16</sub>	Interrupt request register 1 (IREQ1)
003D <sub>16</sub>	Interrupt request register 2 (IREQ2)
003E <sub>16</sub>	Interrupt control register 1 (ICON1)
003F <sub>16</sub>	Interrupt control register 2 (ICON2)
0EF6 <sub>16</sub>	Toff1 time set register (TOFF1)
0EF7 <sub>16</sub>	Toff2 time set register (TOFF2)
0EF8 <sub>16</sub>	FLD data pointer (FLDDP)
0EF9 <sub>16</sub>	Port P4 FLD/Port switch register (P4FPR)
0EFA <sub>16</sub>	Port P5 FLD/Port switch register (P5FPR)
0EFB <sub>16</sub>	Port P6 FLD/Port switch register (P6FPR)
0EFC <sub>16</sub>	FLD output control register (FLDCON)
0EFD <sub>16</sub>	Buzzer output control register (BUZCON)
0EFE <sub>16</sub>	Flash memory control register (FCON)
0EFF <sub>16</sub>	Flash command register (FCMD)
