

LOW DROP VOLTAGE REGULATOR

1 FEATURES

- OPERATING DC SUPPLY VOLTAGE RANGE 5.6V TO 31V
- LOW QUIESCENT CURRENT (6µA Typ. @ 25°C with Enable Low)
- HIGH PRECISION OUTPUT VOLTAGE (2%)
- LOW DROPOUT VOLTAGE LESS THAN 0.5V
- RESET CIRCUIT SENSING THE OUTPUT VOLTAGE DOWN TO 1V
- PROGRAMMABLE RESET PULSE DELAY WITH EXTERNAL CAPACITOR
- WATCHDOG
- PROGRAMMABLE WATCHDOG TIMER WITH EXTERNAL CAPACITOR
- THERMAL SHUTDOWN AND SHORT CIRCUIT PROTECTION
- AUTOMOTIVE TEMPERATURE RANGE (Tj = -40°C TO 150°C)
- ENABLE INPUT FOR ENABLING/DISABLING THE VOLTAGE REGULATOR OUTPUT

- Note: 1. see fig4 (behavior of output current versus regulated voltage Vo)
 - 2. guaranteed by design
 - 3. When Vo becomes lower than 4V, the reset reaction time decreases down to 2µs assuring a faster reset condition in this particular case.

2 **VOLTAGE REGULATOR**

The voltage regulator uses a p-channel MOS transistor as a regulating element. With this structure a low dropout voltage at current up to 150mA is achieved. The output voltage is regulated up to transient input supply voltage of 40V. No functional interruption due to over-voltage pulses is generated. The high precision of the output voltage is obtained with a pre-trimmed reference voltage. A short circuit protection to GND is provided.

Figure 4. Behavior of output current versus regulated voltage Vo (see a.m. Note 1)

3 RESET

The reset circuit monitors the output voltage Vo. If the output voltage drops below Vo th then Res becomes low with a delay time trr. Real trr value changes as a non-linear function of delta $(V_{o-th} - V_o)$. The reset low signal is guaranteed for an output voltage Vo greater than 1V.

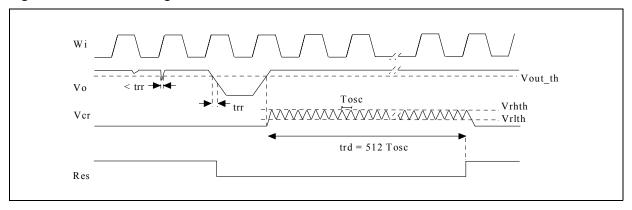

When the output voltage becomes higher than Vo_th then Res goes high with a delay trd. This delay is obtained by 512 periods of an oscillator (see fig. 5). The oscillator period is given by:

$$\mathsf{T}_{\mathsf{osc}} = \frac{[(\mathsf{V}_{\mathsf{rhth}} - \mathsf{V}_{\mathsf{rlth}}) \cdot \mathsf{C}_{\mathsf{tr}}]}{\mathsf{I}_{\mathsf{cr}}} + \frac{[(\mathsf{V}_{\mathsf{rhth}} - \mathsf{V}_{\mathsf{rlth}}) \cdot \mathsf{C}_{\mathsf{tr}}]}{\mathsf{I}_{\mathsf{dr}}}$$

and reset pulse delay trd is given by:

$$t_{rd} = 512 \times T_{osc}$$

Figure 5. Reset Time Diagram.

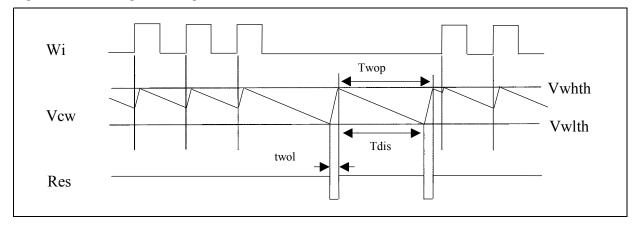

4 WATCHDOG

The watchdog input Wi monitors a connected microcontroller. If pulses are missing, the reset output Res is set to low. The pulse sequence time can be set within a wide range thorough the external capacitor C_{tw} . The watchdog circuit discharges the capacitor C_{tw} with the constant current lcwd. If the lower threshold Vwlth is reached, a watchdog reset is generated. To prevent this reset, the microcontroller must generate a positive edge during the discharge of the capacitor before the voltage has reached the threshold V_{wlth} . In order to calculate the minimum time Tdis during which the microcontroller must generate the positive edge, the following equation can be used:

$$(V_{whth} - V_{wlth}) \times C_{tw} = I_{cwd} \times T_{dis}$$

Each W_i positive edge switches the current source from discharging to charging; the same happens when the lower V_{wlth} threshold is reached. When the voltage reaches the upper threshold V_{whth} the current switches from charging to discharging. The result is a saw tooth voltage at the watchdog timer capacitor C_{tw} .
