## Keep safety first in your circuit designs!

1. Renesas Technology Corp. puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage.  
Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of nonflammable material or (iii) prevention against any malfunction or mishap.

## Notes regarding these materials

1. These materials are intended as a reference to assist our customers in the selection of the Renesas Technology Corp. product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Renesas Technology Corp. or a third party.
2. Renesas Technology Corp. assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.
3. All information contained in these materials, including product data, diagrams, charts, programs and algorithms represents information on products at the time of publication of these materials, and are subject to change by Renesas Technology Corp. without notice due to product improvements or other reasons. It is therefore recommended that customers contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor for the latest product information before purchasing a product listed herein.  
The information described here may contain technical inaccuracies or typographical errors. Renesas Technology Corp. assumes no responsibility for any damage, liability, or other loss rising from these inaccuracies or errors.  
Please also pay attention to information published by Renesas Technology Corp. by various means, including the Renesas Technology Corp. Semiconductor home page (<http://www.renesas.com>).
4. When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Renesas Technology Corp. assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.
5. Renesas Technology Corp. semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
6. The prior written approval of Renesas Technology Corp. is necessary to reprint or reproduce in whole or in part these materials.
7. If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination.  
Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.
8. Please contact Renesas Technology Corp. for further details on these materials or the products contained therein.

## General Precautions on Handling of Product

### 1. Treatment of NC Pins

Note: Do not connect anything to the NC pins.

The NC (not connected) pins are either not connected to any of the internal circuitry or are used as test pins or to reduce noise. If something is connected to the NC pins, the operation of the LSI is not guaranteed.

### 2. Treatment of Unused Input Pins

Note: Fix all unused input pins to high or low level.

Generally, the input pins of CMOS products are high-impedance input pins. If unused pins are in their open states, intermediate levels are induced by noise in the vicinity, a pass-through current flows internally, and a malfunction may occur.

### 3. Processing before Initialization

Note: When power is first supplied, the product's state is undefined.

The states of internal circuits are undefined until full power is supplied throughout the chip and a low level is input on the reset pin. During the period where the states are undefined, the register settings and the output state of each pin are also undefined. Design your system so that it does not malfunction because of processing while it is in this undefined state. For those products which have a reset function, reset the LSI immediately after the power supply has been turned on.

### 4. Prohibition of Access to Undefined or Reserved Addresses

Note: Access to undefined or reserved addresses is prohibited.

The undefined or reserved addresses may be used to expand functions, or test registers may have been allocated to these addresses. Do not access these registers; the system's operation is not guaranteed if they are accessed.

# Configuration of This Manual

This manual comprises the following items:

1. General Precautions on Handling of Product
2. Configuration of This Manual
3. Preface
4. Contents
5. Overview
6. Description of Functional Modules
  - CPU and System-Control Modules
  - On-Chip Peripheral Modules

The configuration of the functional description of each module differs according to the module. However, the generic style includes the following items:

- i) Feature
- ii) Input/Output Pin
- iii) Register Description
- iv) Operation
- v) Usage Note

When designing an application system that includes this LSI, take notes into account. Each section includes notes in relation to the descriptions given, and usage notes are given, as required, as the final part of each section.

7. List of Registers
8. Electrical Characteristics
9. Appendix
10. Main Revisions and Additions in this Edition (only for revised versions)

The list of revisions is a summary of points that have been revised or added to earlier versions. This does not include all of the revised contents. For details, see the actual locations in this manual.

11. Index

# Preface

The H8SX/1520R Group is a single-chip microcomputer made up of the high-speed internal 32-bit H8SX CPU as its core, and the peripheral functions required to configure a system. The H8SX CPU is upward compatible with the H8/300, H8/300H, and H8S CPUs.

**Target Users:** This manual was written for users who will be using the H8SX/1520R Group in the design of application systems. Target users are expected to understand the fundamentals of electrical circuits, logical circuits, and microcomputers.

**Objective:** This manual was written to explain the hardware functions and electrical characteristics of the H8SX/1520R Group to the target users.  
Refer to the H8SX Family Software Manual for a detailed description of the instruction set.

Notes on reading this manual:

In order to understand the overall functions of the chip

Read the manual according to the contents. This manual can be roughly categorized into parts on the CPU, system control functions, and peripheral functions.

In order to understand the details of the CPU's functions

Read the H8SX Family Software Manual.

In order to understand the details of a register when its name is known

Read the index that is the final part of the manual to find the page number of the entry on the register. The addresses, bits, and initial values of the registers are summarized in section 20, List of Registers.

**Examples:**    **Register name:**    The following notation is used for cases when the same or a similar function, e.g. 16-bit timer pulse unit or serial communication interface, is implemented on more than one channel:

XXX\_N (XXX is the register name and N is the channel number)

**Bit order:**    The MSB is on the left and the LSB is on the right.

**Number notation:**    Binary is B'xxxx, hexadecimal is H'xxxx, decimal is xxxx.

**Signal notation:**    An overbar is added to a low-active signal:  $\overline{\text{xxxx}}$

**Related Manuals:**    The latest versions of all related manuals are available from our web site. Please ensure you have the latest versions of all documents you require.

5.6	Interrupt Control Modes and Interrupt Operation .....	110
5.6.1	Interrupt Control Mode 0.....	110
5.6.2	Interrupt Control Mode 2.....	112
5.6.3	Interrupt Exception Handling Sequence .....	114
5.6.4	Interrupt Response Times .....	115
5.6.5	DMAC Activation by Interrupt.....	116
5.7	CPU Priority Control Function Over DMAC .....	118
5.8	Usage Notes .....	121
5.8.1	Conflict between Interrupt Generation and Disabling .....	121
5.8.2	Instructions that Disable Interrupts .....	122
5.8.3	Times when Interrupts are Disabled .....	122
5.8.4	Interrupts during Execution of EEPMOV Instruction.....	122
5.8.5	Interrupts during Execution of MOVMD and MOVSD Instructions.....	122
5.8.6	Interrupt Flags of Peripheral Modules .....	123

Section 6	Bus Controller (BSC)	125
6.1	Features	125
6.2	Register Descriptions	126
6.2.1	Bus Control Register 2 (BCR2)	126
6.3	Bus Configuration	127
6.4	Multi-Clock Function	128
6.5	Internal Bus	129
6.5.1	Access to Internal Address Space	129
6.6	Write Data Buffer Function	130
6.6.1	Write Data Buffer Function for Peripheral Module	130
6.7	Bus Arbitration	131
6.7.1	Operation	131
6.7.2	Bus Transfer Timing	131
6.8	Bus Controller Operation in Reset	132
6.9	Usage Notes	132
Section 7	DMA Controller (DMAC)	133
7.1	Features	133
7.2	Register Descriptions	136
7.2.1	DMA Source Address Register (DSAR)	137
7.2.2	DMA Destination Address Register (DDAR)	138
7.2.3	DMA Offset Register (DOFR)	139
7.2.4	DMA Transfer Count Register (DTCR)	140
7.2.5	DMA Block Size Register (DBSR)	141
7.2.6	DMA Mode Control Register (DMDR)	142
7.2.7	DMA Address Control Register (DACR)	151
7.2.8	DMA Module Request Select Register (DMRSR)	157
7.3	Transfer Modes	157
7.4	Operations	158
7.4.1	Address Modes	158
7.4.2	Transfer Modes	162
7.4.3	Activation Sources	166
7.4.4	Bus Access Modes	168
7.4.5	Extended Repeat Area Function	170
7.4.6	Address Update Function using Offset	172
7.4.7	Register during DMA Transfer	176
7.4.8	Priority of Channels	181
7.4.9	DMA Basic Bus Cycle	182
7.4.10	Bus Cycles in Dual Address Mode	183
7.4.11	Bus Cycles in Single Address Mode	191

7.5	DMA Transfer End .....	196
7.6	Relationship among DMAC and Other Bus Masters .....	198
7.6.1	CPU Priority Control Function Over DMAC .....	198
7.6.2	Bus Arbitration among DMAC and Other Bus Masters .....	199
7.7	Interrupt Sources .....	200
7.8	Notes on Usage .....	203
<b>Section 8 I/O Ports .....</b>		<b>205</b>
8.1	Register Descriptions .....	210
8.1.1	Data Direction Register (PnDDR) (n = 1 to 3, 6, A, D, H, J, and K) .....	212
8.1.2	Data Register (PnDR) (n = 1 to 3, 6, A, D, H, J, and K) .....	212
8.1.3	Port Register (PORTn) (n = 1 to 6, A, D, H, J, and K) .....	213
8.1.4	Input Buffer Control Register (PnICR) (n = 1 to 6, A, D, H, J, and K) .....	213
8.1.5	Pull-Up MOS Control Register (PnPCR) (n = D, H, J, and K) .....	214
8.1.6	Open-Drain Control Register (PnODR) (n = 2) .....	215
8.1.7	Port H Realtime Input Data Register (PHRTIDR) .....	215
8.2	Output Buffer Control .....	216
8.2.1	Port 1 .....	216
8.2.2	Port 2 .....	219
8.2.3	Port 3 .....	221
8.2.4	Port 6 .....	225
8.2.5	Port A .....	227
8.2.6	Port D .....	230
8.2.7	Port H .....	233
8.2.8	Port J .....	233
8.2.9	Port K .....	236
8.3	Port Function Controller .....	243
8.3.1	Port Function Control Register 9 (PFCR9) .....	243
8.3.2	Port Function Control Register A (PFCRA) .....	245
8.3.3	Port Function Control Register B (PFCRB) .....	247
8.4	Usage Notes .....	249
8.4.1	Notes on Input Buffer Control Register (ICR) Setting .....	249
8.4.2	Notes on Port Function Control Register (PFCR) Settings .....	249
<b>Section 9 16-Bit Timer Pulse Unit (TPU) .....</b>		<b>251</b>
9.1	Features .....	251
9.2	Input/Output Pins .....	258
9.3	Register Descriptions .....	260
9.3.1	Timer Control Register (TCR) .....	265
9.3.2	Timer Mode Register (TMDR) .....	270

9.3.3	Timer I/O Control Register (TIOR).....	272
9.3.4	Timer Interrupt Enable Register (TIER).....	290
9.3.5	Timer Status Register (TSR).....	292
9.3.6	Timer Counter (TCNT).....	296
9.3.7	Timer General Register (TGR).....	296
9.3.8	Timer Start Register (TSTR).....	297
9.3.9	Timer Synchronous Register (TSYR).....	298
9.4	Operation.....	299
9.4.1	Basic Functions.....	299
9.4.2	Synchronous Operation.....	305
9.4.3	Buffer Operation.....	307
9.4.4	Cascaded Operation.....	311
9.4.5	PWM Modes.....	313
9.4.6	Phase Counting Mode.....	318
9.5	Interrupt Sources.....	326
9.6	DMAC Activation.....	329

# Section 1 Overview

## 1.1 Features

- 32-bit high-speed H8SX CPU  
Upward compatible with the H8/300 CPU, H8/300H CPU, and H8S CPU  
Sixteen 16-bit general registers  
87 basic instructions
- Extensive peripheral functions  
DMA controller (DMAC)  
16-bit timer pulse unit (TPU)  
Programmable pulse generator (PPG)\*  
Watch dog timer (WDT)  
Serial communication interface (SCI) can be used in asynchronous and clocked synchronous mode  
Controller area network (RCAN-ET)  
Synchronous serial communication unit (SSU)  
10-bit A/D converter  
Clock pulse generator

Note: \* Supported only by the H8SX/1527R.

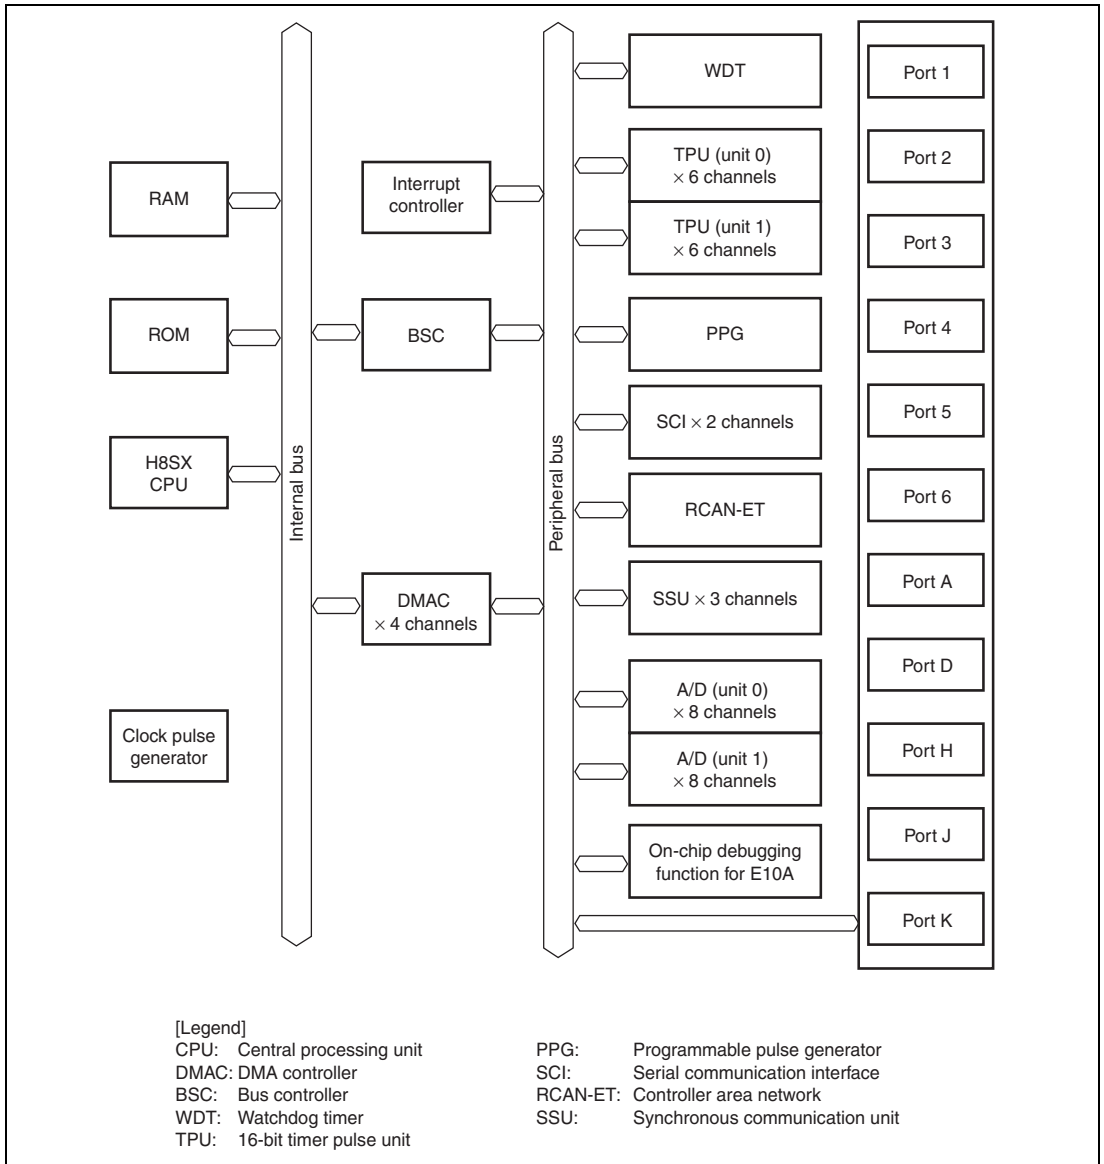

- On-chip memory

Product Classification		Product Model	ROM	RAM
Flash memory version	H8SX/1527R	R5F61527R	256 kbytes	12 kbytes
	H8SX/1525R	R5F61525R	256 kbytes	12 kbytes

- General I/O port  
65 input/output ports  
17 input ports
- Supports power-down modes
- Small package

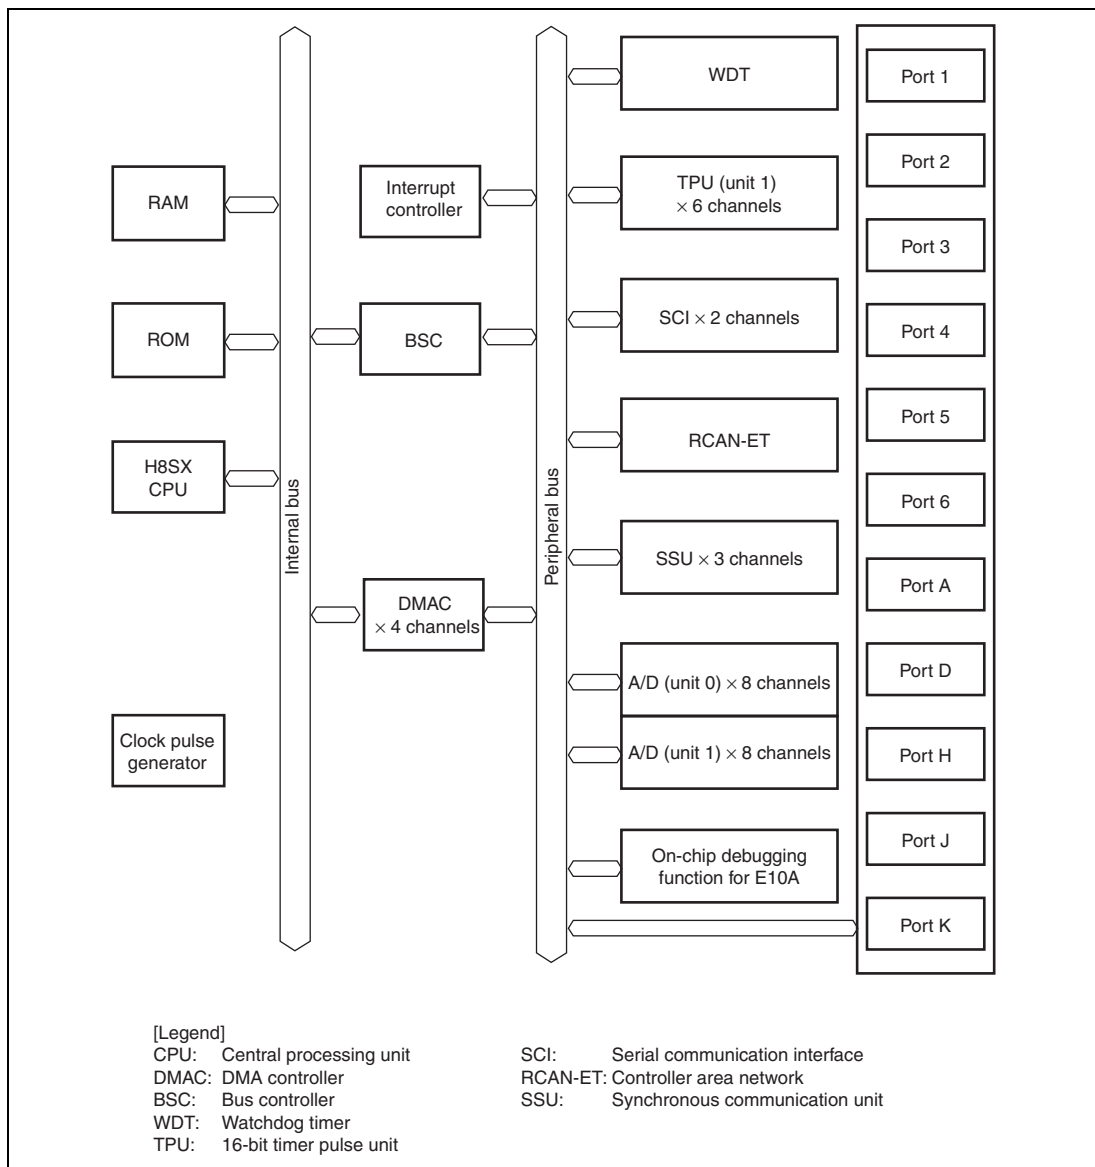

Package	Code	Body Size	Pin Pitch
QFP-100	PRQP0100KB-A (FP-100M)	14.0 × 14.0 mm	0.50 mm

## 1.2 Block Diagram

**Figure 1.2 Block Diagram of H8SX/1525R**

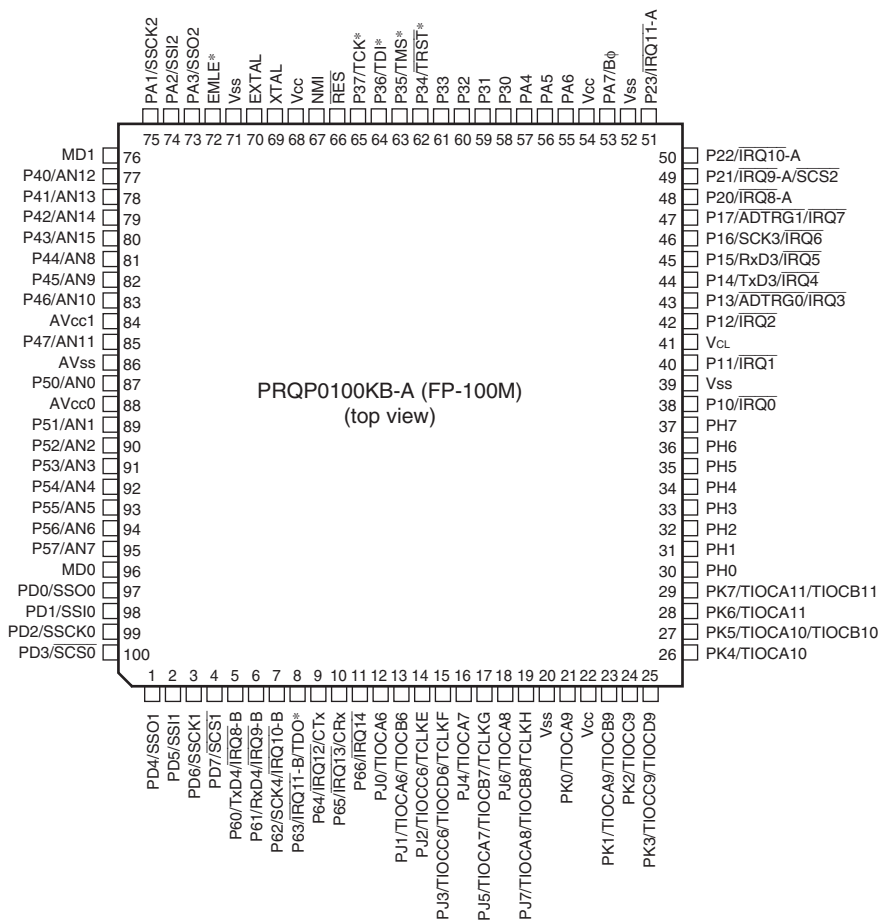

# 1.3 Pin Assignments

## 1.3.1 Pin Assignments

Note: \* The EMLE (emulator enable) pin enables/disables the on-chip debugging functions. When the EMLE pin is driven high, the TDO, TDI, TCK, TMS, and TRST pins are used specific for the E10A. In this case, other pin functions are disabled.

**Figure 1.3 Pin Assignments of H8SX/1527R**

Note: \* The EMLE (emulator enable) pin enables/disables the on-chip debugging functions. When the EMLE pin is driven high, the TDO, TDI, TCK, TMS, and TRST pins are used specific for the E10A. In this case, other pin functions are disabled.

**Figure 1.4 Pin Assignments of H8SX/1525R**

- Notes:
1. Not supported by the H8SX/1525R.
  2. The EMLE (emulator enable) pin enables/disables the on-chip debugging functions. When the EMLE pin is driven high, the TDO, TDI, TCK, TMS, and TRST pins are used specific for the E10A. In this case, other pin functions are disabled.

### 1.3.3 Pin Functions

**Table 1.2 Pin Functions**

Classifi- cation	Abbreviation	Pin Number		I/O	Description
		H8SX/1527R	H8SX/1525R		
Power supply	V <sub>CC</sub>	22, 54, 68	22, 54, 68	Input	Power supply pins. Connect to the system power supply.
	V <sub>CL</sub>	41	41	Input	Connect to VSS via a 0.1- $\mu$ F capacitor (place the capacitor close to this pin).
	V <sub>SS</sub>	20, 39, 52, 71	20, 39, 52, 71	Input	Ground pins. Connect to the system power supply (0 V).
Clock	XTAL	69	69	Input	Pins for a crystal resonator. External clock can be input to the EXTAL pin. For a connection example, see section 18, Clock Pulse Generator.
	EXTAL	70	70	Input	
	B $\phi$	53	53	Output	Supplies the system clock to external devices.
Operating mode control	MD1	76	76	Input	Pins for setting the operating mode. The signal levels of these pins must not be changed during operation.
	MD0	96	96		
System control	$\overline{\text{RES}}$	66	66	Input	Reset signal input pin. This LSI enters the reset state when this signal goes low.
	EMLE	72	72	Input	Input pin for on-chip emulator enable signal. Normally the signal level should be fixed low.

## Section 2 CPU

The H8SX CPU is a high-speed CPU with an internal 32-bit architecture that is upward-compatible with the H8/300, H8/300H, and H8S CPUs.

The H8SX CPU has sixteen 16-bit general registers, can handle a 4-Gbyte linear address space, and is ideal for a realtime control system.

### 2.1 Features

- Upward-compatible with H8/300, H8/300H, and H8S CPUs
  - Can execute H8/300, H8/300H, and H8S/2000 object programs
- Sixteen 16-bit general registers
  - Also usable as sixteen 8-bit registers or eight 32-bit registers
- 87 basic instructions
  - 8/16/32-bit arithmetic and logic instructions
  - Multiply and divide instructions
  - Bit field transfer instructions
  - Powerful bit-manipulation instructions
  - Bit condition branch instructions
  - Multiply-and-accumulate instruction
- Eleven addressing modes
  - Register direct [Rn]
  - Register indirect [@ERn]
  - Register indirect with displacement [@(d:2,ERn), @(d:16,ERn), or @(d:32,ERn)]
  - Index register indirect with displacement [@(d:16,RnL.B), @(d:32,RnL.B), @(d:16,Rn.W), @(d:32,Rn.W), @(d:16,ERn.L), or @(d:32,ERn.L)]
  - Register indirect with pre-/post-increment or pre-/post-decrement [ @+ERn, @ERn+, @-ERn, or @ERn-]
  - Absolute address [ @aa:8, @aa:16, @aa:24, or @aa:32]
  - Immediate [ #xx:3, #xx:4, #xx:8, #xx:16, or #xx:32]
  - Program-counter relative [ @(d:8,PC) or @(d:16,PC)]
  - Program-counter relative with index register [ @(RnL.B,PC), @(Rn.W,PC), or @(ERn.L,PC)]
  - Memory indirect [ @@aa:8]
  - Extended memory indirect [ @@vec:7]

- Two base registers
  - Vector base register
  - Short address base register
- 4-Gbyte address space
  - Program: 4 Gbytes
  - Data: 4 Gbytes
- High-speed operation
  - All frequently-used instructions executed in one or two states
  - 8/16/32-bit register-register add/subtract: 1 state
  - $8 \times 8$ -bit register-register multiply: 1 state
  - $16 \div 8$ -bit register-register divide: 10 states
  - $16 \times 16$ -bit register-register multiply: 1 state
  - $32 \div 16$ -bit register-register divide: 18 states
  - $32 \times 32$ -bit register-register multiply: 5 states
  - $32 \div 32$ -bit register-register divide: 18 states
- Four CPU operating modes
  - Normal mode
  - Middle mode
  - Advanced mode
  - Maximum mode
- Power-down modes
  - Transition is made by execution of SLEEP instruction
  - Choice of CPU operating clocks

- 
- Notes: 1. Advanced mode is only supported as the CPU operating mode of the H8SX/1520R Group. Normal, middle, and maximum modes are not supported.
2. The multiplier and divider are supported by the H8SX/1520R Group.
3. In the H8SX/1520R Group, an instruction is fetched in 32-bit mode.
-

## 2.2 CPU Operating Modes

The H8SX CPU has four operating modes: normal, middle, advanced and maximum modes. For details on mode settings, see section 3.1, Operating Mode Selection.

**Figure 2.1 CPU Operating Modes**

### 2.2.1 Normal Mode

The exception vector table and stack have the same structure as in the H8/300 CPU.

Note: Normal mode is not supported in this LSI.

- Address Space

The maximum address space of 64 kbytes can be accessed.

- Extended Registers (En)

The extended registers (E0 to E7) can be used as 16-bit registers, or as the upper 16-bit segments of 32-bit registers. When the extended register En is used as a 16-bit register it can contain any value, even when the corresponding general register Rn is used as an address register. (If the general register Rn is referenced in the register indirect addressing mode with pre-/post-increment or pre-/post-decrement and a carry or borrow occurs, however, the value in the corresponding extended register En will be affected.)

- Instruction Set

All instructions and addressing modes can be used. Only the lower 16 bits of effective addresses (EA) are valid.

- Exception Vector Table and Memory Indirect Branch Addresses

In normal mode, the top area starting at H'0000 is allocated to the exception vector table. One branch address is stored per 16 bits. The structure of the exception vector table is shown in figure 2.2.

**Figure 2.2 Exception Vector Table (Normal Mode)**

The memory indirect (@@aa:8) and extended memory indirect (@@vec:7) addressing modes are used in the JMP and JSR instructions. An 8-bit absolute address included in the instruction code specifies a memory location. Execution branches to the contents of the memory location.

- Stack Structure

The stack structure of PC at a subroutine branch and that of PC and CCR at an exception handling are shown in figure 2.3. The PC contents are saved or restored in 16-bit units.

**Figure 2.3 Stack Structure (Normal Mode)**

## 2.2.2 Middle Mode

The program area in middle mode is extended to 16 Mbytes as compared with that in normal mode.

- Address Space

The maximum address space of 16 Mbytes can be accessed as a total of the program and data areas. For individual areas, up to 16 Mbytes of the program area or up to 64 kbytes of the data area can be allocated.

- Extended Registers (En)

The extended registers (E0 to E7) can be used as 16-bit registers, or as the upper 16-bit segments of 32-bit registers. When the extended register En is used as a 16-bit register (in other than the JMP and JSR instructions), it can contain any value even when the corresponding general register Rn is used as an address register. (If the general register Rn is referenced in the register indirect addressing mode with pre-/post-increment or pre-/post-decrement and a carry or borrow occurs, however, the value in the corresponding extended register En will be affected.)

- Instruction Set

All instructions and addressing modes can be used. Only the lower 16 bits of effective addresses (EA) are valid and the upper eight bits are sign-extended.

- Exception Vector Table and Memory Indirect Branch Addresses

In middle mode, the top area starting at H'000000 is allocated to the exception vector table. One branch address is stored per 32 bits. The upper eight bits are ignored and the lower 24 bits are stored. The structure of the exception vector table is shown in figure 2.4.

The memory indirect (@@aa:8) and extended memory indirect (@@vec:7) addressing modes are used in the JMP and JSR instructions. An 8-bit absolute address included in the instruction code specifies a memory location. Execution branches to the contents of the memory location.

In middle mode, an operand is a 32-bit (longword) operand, providing a 32-bit branch address. The upper eight bits are reserved and assumed to be H'00.

- Stack Structure

The stack structure of PC at a subroutine branch and that of PC and CCR at an exception handling are shown in figure 2.5. The PC contents are saved or restored in 24-bit units.

### 2.2.3 Advanced Mode

The data area is extended to 4 Gbytes as compared with that in middle mode.

- Address Space

The maximum address space of 4 Gbytes can be linearly accessed. For individual areas, up to 16 Mbytes of the program area and up to 4 Gbytes of the data area can be allocated.

- Extended Registers (En)

The extended registers (E0 to E7) can be used as 16-bit registers, or as the upper 16-bit segments of 32-bit registers or address registers.

- Instruction Set

All instructions and addressing modes can be used.

- Exception Vector Table and Memory Indirect Branch Addresses

In advanced mode, the top area starting at H'00000000 is allocated to the exception vector table. One branch address is stored per 32 bits. The upper eight bits are ignored and the lower 24 bits are stored. The structure of the exception vector table is shown in figure 2.4.

**Figure 2.4 Exception Vector Table (Middle and Advanced Modes)**

The memory indirect (@@aa:8) and extended memory indirect (@@vec:7) addressing modes are used in the JMP and JSR instructions. An 8-bit absolute address included in the instruction code specifies a memory location. Execution branches to the contents of the memory location. In advanced mode, an operand is a 32-bit (longword) operand, providing a 32-bit branch address. The upper eight bits are reserved and assumed to be H'00.

- Stack Structure

The stack structure of PC at a subroutine branch and that of PC and CCR at an exception handling are shown in figure 2.5. The PC contents are saved or restored in 24-bit units.

**Figure 2.5 Stack Structure (Middle and Advanced Modes)**

### 2.2.4 Maximum Mode

The program area is extended to 4 Gbytes as compared with that in advanced mode.

- Address Space

The maximum address space of 4 Gbytes can be linearly accessed.

- Extended Registers (En)

The extended registers (E0 to E7) can be used as 16-bit registers or as the upper 16-bit segments of 32-bit registers or address registers.

- Instruction Set

All instructions and addressing modes can be used.

- Exception Vector Table and Memory Indirect Branch Addresses

In maximum mode, the top area starting at H'00000000 is allocated to the exception vector table. One branch address is stored per 32 bits. The structure of the exception vector table is shown in figure 2.6.

**Figure 2.6 Exception Vector Table (Maximum Modes)**

The memory indirect (@@aa:8) and extended memory indirect (@@vec:7) addressing modes are used in the JMP and JSR instructions. An 8-bit absolute address included in the instruction code specifies a memory location. Execution branches to the contents of the memory location. In maximum mode, an operand is a 32-bit (longword) operand, providing a 32-bit branch address.

- Stack Structure

The stack structure of PC at a subroutine branch and that of PC and CCR at an exception handling are shown in figure 2.7. The PC contents are saved or restored in 32-bit units. The EXR contents are saved or restored regardless of whether or not EXR is in use.

**Figure 2.7 Stack Structure (Maximum Mode)**

## 2.3 Instruction Fetch

The H8SX CPU has two modes for instruction fetch: 16-bit and 32-bit modes. It is recommended that the mode be set according to the bus width of the memory in which a program is stored. The instruction-fetch mode setting does not affect operation other than instruction fetch such as data accesses.

Note: In the H8SX/1520R Group, an instruction is fetched in 32-bit mode.

## 2.4 Address Space

Figure 2.8 shows a memory map of the H8SX CPU. The address space differs depending on the CPU operating mode.

Figure 2.8 Memory Map

## 2.5 Registers

The H8SX CPU has the internal registers shown in figure 2.9. There are two types of registers: general registers and control registers. The control registers are the 32-bit program counter (PC), 8-bit extended control register (EXR), 8-bit condition-code register (CCR), 32-bit vector base register (VBR), 32-bit short address base register (SBR), and 64-bit multiply-accumulate register (MAC).

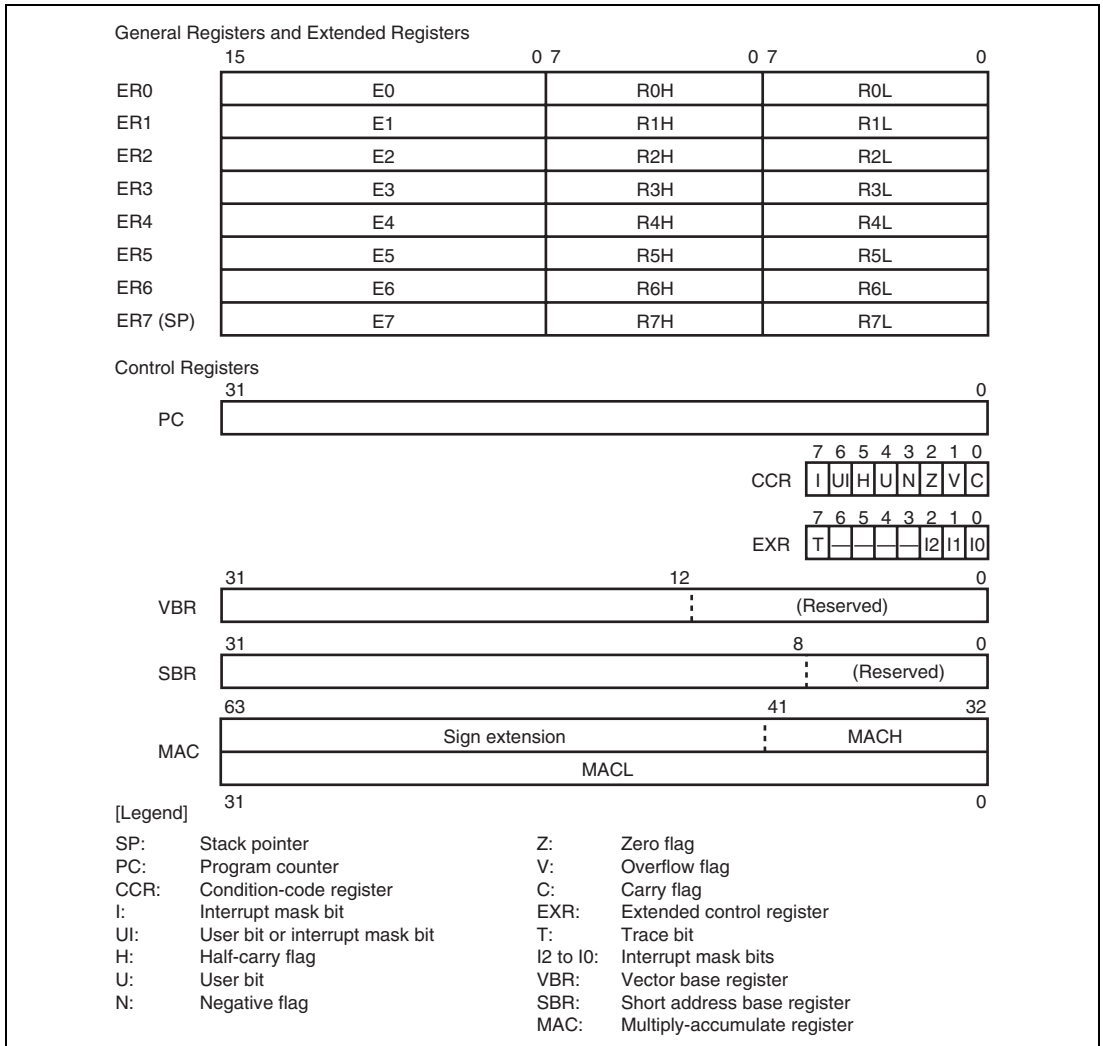

Figure 2.9 CPU Registers

## 2.5.1 General Registers

The H8SX CPU has eight 32-bit general registers. These general registers are all functionally alike and can be used as both address registers and data registers. When a general register is used as a data register, it can be accessed as a 32-bit, 16-bit, or 8-bit register. Figure 2.10 illustrates the usage of the general registers.

When the general registers are used as 32-bit registers or address registers, they are designated by the letters ER (ER0 to ER7).

When the general registers are used as 16-bit registers, the ER registers are divided into 16-bit general registers designated by the letters E (E0 to E7) and R (R0 to R7). These registers are functionally equivalent, providing a maximum sixteen 16-bit registers. The E registers (E0 to E7) are also referred to as extended registers.

When the general registers are used as 8-bit registers, the R registers are divided into 8-bit general registers designated by the letters RH (R0H to R7H) and RL (R0L to R7L). These registers are functionally equivalent, providing a maximum sixteen 8-bit registers.

The general registers ER (ER0 to ER7), R (R0 to R7), and RL (R0L to R7L) are also used as index registers. The size in the operand field determines which register is selected.

The usage of each register can be selected independently.

**Figure 2.10 Usage of General Registers**

General register ER7 has the function of stack pointer (SP) in addition to its general-register function, and is used implicitly in exception handling and subroutine branches. Figure 2.11 shows the stack.

**Figure 2.11 Stack**

### 2.5.2 Program Counter (PC)

PC is a 32-bit counter that indicates the address of the next instruction the CPU will execute. The length of all CPU instructions is 16 bits (one word) or a multiple of 16 bits, so the least significant bit is ignored. (When the instruction code is fetched, the least significant bit is regarded as 0.)

### 2.5.3 Condition-Code Register (CCR)

CCR is an 8-bit register that contains internal CPU status information, including an interrupt mask (I) and user (UI, U) bits and half-carry (H), negative (N), zero (Z), overflow (V), and carry (C) flags.

Operations can be performed on the CCR bits by the LDC, STC, ANDC, ORC, and XORC instructions. The N, Z, V, and C flags are used as branch conditions for conditional branch (Bcc) instructions.

Bit	Bit Name	Initial Value	R/W	Description
7	I	1	R/W	Interrupt Mask Bit Masks interrupts when set to 1. This bit is set to 1 at the start of an exception handling.
6	UI	Undefined	R/W	User Bit or Interrupt Mask Bit Can be written to and read from by software using the LDC, STC, ANDC, ORC, and XORC instructions. This bit can also be used as an interrupt mask bit.

Bit	Bit Name	Initial Value	R/W	Description
5	H	Undefined	R/W	<p>Half-Carry Flag</p> <p>When the ADD.B, ADDX.B, SUB.B, SUBX.B, CMP.B, or NEG.B instruction is executed, this flag is set to 1 if there is a carry or borrow at bit 3, and cleared to 0 otherwise. When the ADD.W, SUB.W, CMP.W, or NEG.W instruction is executed, this flag is set to 1 if there is a carry or borrow at bit 11, and cleared to 0 otherwise. When the ADD.L, SUB.L, CMP.L, or NEG.L instruction is executed, this flag is set to 1 if there is a carry or borrow at bit 27, and cleared to 0 otherwise.</p>
4	U	Undefined	R/W	<p>User Bit</p> <p>Can be written to and read from by software using the LDC, STC, ANDC, ORC, and XORC instructions.</p>
3	N	Undefined	R/W	<p>Negative Flag</p> <p>Stores the value of the most significant bit (regarded as sign bit) of data.</p>
2	Z	Undefined	R/W	<p>Zero Flag</p> <p>Set to 1 to indicate zero data, and cleared to 0 to indicate non-zero data.</p>
1	V	Undefined	R/W	<p>Overflow Flag</p> <p>Set to 1 when an arithmetic overflow occurs, and cleared to 0 otherwise.</p>
0	C	Undefined	R/W	<p>Carry Flag</p> <p>Set to 1 when a carry occurs, and cleared to 0 otherwise. A carry has the following types:</p> <ul style="list-style-type: none"> <li>• Carry from the result of addition</li> <li>• Borrow from the result of subtraction</li> <li>• Carry from the result of shift or rotation</li> </ul> <p>The carry flag is also used as a bit accumulator by bit manipulation instructions.</p>

### 2.5.4 Extended Control Register (EXR)

EXR is an 8-bit register that contains the trace bit (T) and three interrupt mask bits (I2 to I0).

Operations can be performed on the EXR bits by the LDC, STC, ANDC, ORC, and XORC instructions.

For details, see the hardware manual for the corresponding product.

Bit	Bit Name	Initial Value	R/W	Description
7	T	0	R/W	Trace Bit When this bit is set to 1, a trace exception is generated each time an instruction is executed. When this bit is cleared to 0, instructions are executed in sequence.
6 to 3	—	All 1	R/W	Reserved These bits are always read as 1.
2	I2	1	R/W	Interrupt Mask Bits
1	I1	1	R/W	These bits designate the interrupt mask level (0 to 7).
0	I0	1	R/W	

### 2.5.5 Vector Base Register (VBR)

VBR is a 32-bit register in which the upper 20 bits are valid. The lower 12 bits of this register are read as 0s. This register is a base address of the vector area for exception handlings other than a reset and a CPU address error (extended memory indirect is also out of the target). The initial value is H'00000000. The VBR contents are changed with the LDC and STC instructions.

### 2.5.6 Short Address Base Register (SBR)

SBR is a 32-bit register in which the upper 24 bits are valid. The lower eight bits are read as 0s. In 8-bit absolute address addressing mode (@aa:8), this register is used as the upper address. The initial value is H'FFFFFF00. The SBR contents are changed with the LDC and STC instructions.

### 2.5.7 Multiply-Accumulate Register (MAC)

MAC is a 64-bit register that stores the results of multiply-and-accumulate operations. It consists of two 32-bit registers denoted MACH and MACL. The lower 10 bits of MACH are valid; the upper bits are sign extended. The MAC contents are changed with the MAC, CLRMAC, LDMAC, and STMAC instructions.

### 2.5.8 Initial Values of CPU Registers

Reset exception handling loads the start address from the vector table into the PC, clears the T bit in EXR to 0, and sets the I bits in CCR and EXR to 1. The general registers, MAC, and the other bits in CCR are not initialized. In particular, the initial value of the stack pointer (ER7) is undefined. The SP should therefore be initialized using an MOV.L instruction executed immediately after a reset.

## 2.6 2Data Formats

The H8SX CPU can process 1-bit, 4-bit BCD, 8-bit (byte), 16-bit (word), and 32-bit (longword) data.

Bit-manipulation instructions operate on 1-bit data by accessing bit  $n$  ( $n = 0, 1, 2, \dots, 7$ ) of byte operand data. The DAA and DAS decimal-adjust instructions treat byte data as two digits of 4-bit BCD data.

### 2.6.1 General Register Data Formats

Figure 2.12 shows the data formats in general registers.

[Legend]

- |                          |                            |
|--------------------------|----------------------------|
| ERn: General register ER | RnL: General register RL   |
| En: General register E   | MSB: Most significant bit  |
| Rn: General register R   | LSB: Least significant bit |
| RnH: General register RH |                            |

**Figure 2.12 General Register Data Formats**

## 2.6.2 Memory Data Formats

Figure 2.13 shows the data formats in memory.

The H8SX CPU can access word data and longword data which are stored at any addresses in memory. When word data begins at an odd address or longword data begins at an address other than a multiple of 4, a bus cycle is divided into two or more accesses. For example, when longword data begins at an odd address, the bus cycle is divided into byte, word, and byte accesses. In this case, these accesses are assumed to be individual bus cycles.

However, instructions to be fetched, word and longword data to be accessed during execution of the stack manipulation, branch table manipulation, block transfer instructions, and MAC instruction should be located to even addresses.

When SP (ER7) is used as an address register to access the stack, the operand size should be word size or longword size.

**Figure 2.13 Memory Data Formats**

## 2.7 Instruction Set

The H8SX CPU has 87 types of instructions. The instructions are classified by function as shown in table 2.1. The arithmetic operation, logic operation, shift, and bit manipulation instructions are called operation instruction in this manual.

**Table 2.1 Instruction Classification**

Function	Instructions	Size	Types
Data transfer	MOV	B/W/L	6
	MOVFPE* <sup>6</sup> , MOVTPE* <sup>6</sup>	B	
	POP, PUSH* <sup>1</sup>	W/L	
	LDM, STM	L	
	MOVA	B/W* <sup>2</sup>	
Block transfer	EPMOV	B	3
	MOVMD	B/W/L	
	MOVSD	B	
Arithmetic operations	ADD, ADDX, SUB, SUBX, CMP, NEG, INC, DEC	B/W/L	27
	DAA, DAS	B	
	ADDS, SUBS	L	
	MULXU, DIVXU, MULXS, DIVXS	B/W	
	MULU, DIVU, MULS, DIVS	W/L	
	MULU/U, MULS/U	L	
	EXTU, EXTS	W/L	
	TAS	B	
	MAC	—	
	LDMAC, STMAC	—	
	CLRMAC	—	
	Logic operations	AND, OR, XOR, NOT	
Shift	SHLL, SHLR, SHAL, SHAR, ROTL, ROTR, ROTXL, ROTXR	B/W/L	8
Bit manipulation	BSET, BCLR, BNOT, BTST, BAND, BIAND, BOR, BIOR, BXOR, BIXOR, BLD, BILD, BST, BIST	B	20
	BSET/EQ, BSET/NE, BCLR/EQ, BCLR/NE, BSTZ, BISTZ	B	
	BFLD, BFST	B	

Function	Instructions	Size	Types
Branch	BRA/BS, BRA/BC, BSR/BS, BSR/BC	B* <sup>3</sup>	9
	Bcc* <sup>5</sup> , JMP, BSR, JSR, RTS	—	
	RTS/L	L* <sup>5</sup>	
	BRA/S	—	
System control	TRAPA, RTE, SLEEP, NOP	—	10
	RTE/L	L* <sup>5</sup>	
	LDC, STC, ANDC, ORC, XORC	B/W/L	
		Total	87

## [Legend]

B: Byte size

W: Word size

L: Longword size

- Notes: 1. POP.W Rn and PUSH.W Rn are identical to MOV.W @SP+, Rn and MOV.W Rn, @-SP.  
 POP.L ERn and PUSH.L ERn are identical to MOV.L @SP+, ERn and MOV.L ERn, @-SP.
2. Size of data to be added with a displacement
  3. Size of data to specify a branch condition
  4. Bcc is the generic designation of a conditional branch instruction.
  5. Size of general register to be restored
  6. Not available in this LSI.

## 2.7.1 Instructions and Addressing Modes

Table 2.2 indicates the combinations of instructions and addressing modes that the H8SX CPU can use.

**Table 2.2 Combinations of Instructions and Addressing Modes (1)**

Classification	Instruction	Size	#xx	Rn	@ERn	Addressing Mode				
						@(d,ERn)	@(d, @-ERn/ RnL.B/ Rn.W/ ERn.L)	@-ERn/ @ERn+/ @ERn-/ @+ERn	@aa:16/ @aa:32	—

## [Legend]

d: d:16 or d:32

S: Can be specified as a source operand.

D: Can be specified as a destination operand.

SD: Can be specified as either a source or destination operand or both.

S/D: Can be specified as either a source or destination operand.

S:4: 4-bit immediate data can be specified as a source operand.

- Notes:
1. Only @aa:16 is available.
  2. @ERn+ as a source operand and @-ERn as a destination operand
  3. Specified by ER5 as a source address and ER6 as a destination address for data transfer.
  4. Size of data to be added with a displacement
  5. Only @ERn- is available
  6. When the number of bits to be shifted is 1, 2, 4, 8, or 16
  7. When the number of bits to be shifted is specified by 5-bit immediate data or a general register
  8. Size of data to specify a branch condition
  9. Byte when immediate or register direct, otherwise, word
  10. Only @ERn+ is available
  11. Only @-ERn is available
  12. Not available in this LSI.

## 2.7.2 Table of Instructions Classified by Function

Tables 2.4 to 2.11 summarize the instructions in each functional category. The notation used in these tables is defined in table 2.3.

**Table 2.3 Operation Notation**

Operation Notation	Description
Rd	General register (destination)*
Rs	General register (source)*
Rn	General register*
ERn	General register (32-bit register)
(EAd)	Destination operand
(EAs)	Source operand
EXR	Extended control register
CCR	Condition-code register
VBR	Vector base register
SBR	Short address base register
N	N (negative) flag in CCR
Z	Z (zero) flag in CCR
V	V (overflow) flag in CCR
C	C (carry) flag in CCR
PC	Program counter
SP	Stack pointer
#IMM	Immediate data
disp	Displacement
+	Addition
-	Subtraction
×	Multiplication
÷	Division
^	Logical AND
∨	Logical OR
⊕	Logical exclusive OR
→	Move
~	Logical not (logical complement)
:8/:16/:24/:32	8-, 16-, 24-, or 32-bit length

Note: \* General registers include 8-bit registers (R0H to R7H, R0L to R7L), 16-bit registers (R0 to R7, E0 to E7), and 32-bit registers (ER0 to ER7).

**Table 2.4 Data Transfer Instructions**

<b>Instruction</b>	<b>Size</b>	<b>Function</b>
MOV	B/W/L	#IMM → (EAd), (EAs) → (EAd) Transfers data between immediate data, general registers, and memory.
MOVFPPE*	B	(EAs) → Rd
MOVTPE*	B	Rs → (EAs)
POP	W/L	@SP+ → Rn Restores the data from the stack to a general register.
PUSH	W/L	Rn → @-SP Saves general register contents on the stack.
LDM	L	@SP+ → Rn (register list) Restores the data from the stack to multiple general registers. Two, three, or four general registers which have serial register numbers can be specified.
STM	L	Rn (register list) → @-SP Saves the contents of multiple general registers on the stack. Two, three, or four general registers which have serial register numbers can be specified.
MOVA	B/W	EA → Rd Zero-extends and shifts the contents of a specified general register or memory data and adds them with a displacement. The result is stored in a general register.

Note: \* Not available in this LSI.

**Table 2.5 Block Transfer Instructions**

<b>Instruction</b>	<b>Size</b>	<b>Function</b>
EEPMOV.B EEPMOV.W	B	Transfers a data block.  Transfers byte data which begins at a memory location specified by ER5 to a memory location specified by ER6. The number of byte data to be transferred is specified by R4 or R4L.
MOVMD.B	B	Transfers a data block.  Transfers byte data which begins at a memory location specified by ER5 to a memory location specified by ER6. The number of byte data to be transferred is specified by R4.
MOVMD.W	W	Transfers a data block.  Transfers word data which begins at a memory location specified by ER5 to a memory location specified by ER6. The number of word data to be transferred is specified by R4.
MOVMD.L	L	Transfers a data block.  Transfers longword data which begins at a memory location specified by ER5 to a memory location specified by ER6. The number of longword data to be transferred is specified by R4.
MOVSD.B	B	Transfers a data block with zero data detection.  Transfers byte data which begins at a memory location specified by ER5 to a memory location specified by ER6. The number of byte data to be transferred is specified by R4. When zero data is detected during transfer, the transfer stops and execution branches to a specified address.

**Table 2.6 Arithmetic Operation Instructions**

Instruction	Size	Function
ADD SUB	B/W/L	$(EAd) \pm \#IMM \rightarrow (EAd)$ , $(EAd) \pm (EAs) \rightarrow (EAd)$ Performs addition or subtraction on data between immediate data, general registers, and memory. Immediate byte data cannot be subtracted from byte data in a general register.
ADDX SUBX	B/W/L	$(EAd) \pm \#IMM \pm C \rightarrow (EAd)$ , $(EAd) \pm (EAs) \pm C \rightarrow (EAd)$ Performs addition or subtraction with carry on data between immediate data, general registers, and memory. The addressing mode which specifies a memory location can be specified as register indirect with post-decrement or register indirect.
INC DEC	B/W/L	$Rd \pm 1 \rightarrow Rd$ , $Rd \pm 2 \rightarrow Rd$ Increments or decrements a general register by 1 or 2. (Byte operands can be incremented or decremented by 1 only.)
ADDS SUBS	L	$Rd \pm 1 \rightarrow Rd$ , $Rd \pm 2 \rightarrow Rd$ , $Rd \pm 4 \rightarrow Rd$ Adds or subtracts the value 1, 2, or 4 to or from data in a general register.
DAA DAS	B	$Rd$ (decimal adjust) $\rightarrow Rd$ Decimal-adjusts an addition or subtraction result in a general register by referring to the CCR to produce 2-digit 4-bit BCD data.
MULXU	B/W	$Rd \times Rs \rightarrow Rd$ Performs unsigned multiplication on data in two general registers: either 8 bits $\times$ 8 bits $\rightarrow$ 16 bits, or 16 bits $\times$ 16 bits $\rightarrow$ 32 bits.
MULU	W/L	$Rd \times Rs \rightarrow Rd$ Performs unsigned multiplication on data in two general registers: either 8 bits $\times$ 8 bits $\rightarrow$ 16 bits, or 16 bits $\times$ 16 bits $\rightarrow$ 32 bits.
MULU/U	L	$Rd \times Rs \rightarrow Rd$ Performs unsigned multiplication on data in two general registers (32 bits $\times$ 32 bits $\rightarrow$ upper 32 bits).
MULXS	B/W	$Rd \times Rs \rightarrow Rd$ Performs signed multiplication on data in two general registers: either 8 bits $\times$ 8 bits $\rightarrow$ 16 bits, or 16 bits $\times$ 16 bits $\rightarrow$ 32 bits.
MULS	W/L	$Rd \times Rs \rightarrow Rd$ Performs signed multiplication on data in two general registers: either 16 bits $\times$ 16 bits $\rightarrow$ 16 bits, or 32 bits $\times$ 32 bits $\rightarrow$ 32 bits.
MULS/U	L	$Rd \times Rs \rightarrow Rd$ Performs signed multiplication on data in two general registers (32 bits $\times$ 32 bits $\rightarrow$ upper 32 bits).

Instruction	Size	Function
DIVXU	B/W	$Rd \div Rs \rightarrow Rd$ Performs unsigned division on data in two general registers: either 16 bits $\div$ 8 bits $\rightarrow$ 8-bit quotient and 8-bit remainder, or 32 bits $\div$ 16 bits $\rightarrow$ 16-bit quotient and 16-bit remainder.
DIVU	W/L	$Rd \div Rs \rightarrow Rd$ Performs unsigned division on data in two general registers: either 16 bits $\div$ 16 bits $\rightarrow$ 16-bit quotient, or 32 bits $\div$ 32 bits $\rightarrow$ 32-bit quotient.
DIVXS	B/W	$Rd \div Rs \rightarrow Rd$ Performs signed division on data in two general registers: either 16 bits $\div$ 8 bits $\rightarrow$ 8-bit quotient and 8-bit remainder, or 32 bits $\div$ 16 bits $\rightarrow$ 16-bit quotient and 16-bit remainder.
DIVS	W/L	$Rd \div Rs \rightarrow Rd$ Performs signed division on data in two general registers: either 16 bits $\div$ 16 bits $\rightarrow$ 16-bit quotient, or 32 bits $\div$ 32 bits $\rightarrow$ 32-bit quotient.
CMP	B/W/L	(EAd) – #IMM, (EAd) – (EAs) Compares data between immediate data, general registers, and memory and stores the result in CCR.
NEG	B/W/L	$0 - (EAd) \rightarrow (EAd)$ Takes the two's complement (arithmetic complement) of data in a general register or the contents of a memory location.
EXTU	W/L	(EAd) (zero extension) $\rightarrow$ (EAd) Performs zero-extension on the lower 8 or 16 bits of data in a general register or memory to word or longword size. The lower 8 bits to word or longword, or the lower 16 bits to longword can be zero-extended.
EXTS	W/L	(EAd) (sign extension) $\rightarrow$ (EAd) Performs sign-extension on the lower 8 or 16 bits of data in a general register or memory to word or longword size. The lower 8 bits to word or longword, or the lower 16 bits to longword can be sign-extended.
TAS	B	@ERd – 0, 1 $\rightarrow$ (<bit 7> of @EAd) Tests memory contents, and sets the most significant bit (bit 7) to 1.
MAC	—	(EAs) $\times$ (EAd) + MAC $\rightarrow$ MAC Performs signed multiplication on memory contents and adds the result to MAC.
CLRMAC	—	$0 \rightarrow$ MAC Clears MAC to zero.

Instruction	Size	Function
LDMAC	—	Rs → MAC Loads data from a general register to MAC.
STMAC	—	MAC → Rd Stores data from MAC to a general register.

**Table 2.7 Logic Operation Instructions**

Instruction	Size	Function
AND	B/W/L	$(EAd) \wedge \#IMM \rightarrow (EAd)$ , $(EAd) \wedge (EAs) \rightarrow (EAd)$ Performs a logical AND operation on data between immediate data, general registers, and memory.
OR	B/W/L	$(EAd) \vee \#IMM \rightarrow (EAd)$ , $(EAd) \vee (EAs) \rightarrow (EAd)$ Performs a logical OR operation on data between immediate data, general registers, and memory.
XOR	B/W/L	$(EAd) \oplus \#IMM \rightarrow (EAd)$ , $(EAd) \oplus (EAs) \rightarrow (EAd)$ Performs a logical exclusive OR operation on data between immediate data, general registers, and memory.
NOT	B/W/L	$\sim (EAd) \rightarrow (EAd)$ Takes the one's complement of the contents of a general register or a memory location.

**Table 2.8 Shift Operation Instructions**

<b>Instruction</b>	<b>Size</b>	<b>Function</b>
SHLL	B/W/L	(EAd) (shift) → (EAd)
SHLR		Performs a logical shift on the contents of a general register or a memory location.  The contents of a general register or a memory location can be shifted by 1, 2, 4, 8, or 16 bits. The contents of a general register can be shifted by any bits. In this case, the number of bits is specified by 5-bit immediate data or the lower 5 bits of the contents of a general register.
SHAL	B/W/L	(EAd) (shift) → (EAd)
SHAR		Performs an arithmetic shift on the contents of a general register or a memory location.  1-bit or 2-bit shift is possible.
ROTL	B/W/L	(EAd) (rotate) → (EAd)
ROTR		Rotates the contents of a general register or a memory location.  1-bit or 2-bit rotation is possible.
ROTXL	B/W/L	(EAd) (rotate) → (EAd)
ROTXR		Rotates the contents of a general register or a memory location with the carry bit.  1-bit or 2-bit rotation is possible.

**Table 2.9 Bit Manipulation Instructions**

Instruction	Size	Function
BSET	B	$1 \rightarrow (\text{<bit-No.> of <EAd>})$ Sets a specified bit in the contents of a general register or a memory location to 1. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.
BSET/cc	B	if cc, $1 \rightarrow (\text{<bit-No.> of <EAd>})$ If the specified condition is satisfied, this instruction sets a specified bit in a memory location to 1. The bit number can be specified by 3-bit immediate data, or by the lower three bits of a general register. The Z flag status can be specified as a condition.
BCLR	B	$0 \rightarrow (\text{<bit-No.> of <EAd>})$ Clears a specified bit in the contents of a general register or a memory location to 0. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.
BCLR/cc	B	if cc, $0 \rightarrow (\text{<bit-No.> of <EAd>})$ If the specified condition is satisfied, this instruction clears a specified bit in a memory location to 0. The bit number can be specified by 3-bit immediate data, or by the lower three bits of a general register. The Z flag status can be specified as a condition.
BNOT	B	$\sim (\text{<bit-No.> of <EAd>}) \rightarrow (\text{<bit-No.> of <EAd>})$ Inverts a specified bit in the contents of a general register or a memory location. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.
BTST	B	$\sim (\text{<bit-No.> of <EAd>}) \rightarrow Z$ Tests a specified bit in the contents of a general register or a memory location and sets or clears the Z flag accordingly. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.
BAND	B	$C \wedge (\text{<bit-No.> of <EAd>}) \rightarrow C$ ANDs the carry flag with a specified bit in the contents of a general register or a memory location and stores the result in the carry flag. The bit number is specified by 3-bit immediate data.
BIAND	B	$C \wedge [\sim (\text{<bit-No.> of <EAd>})] \rightarrow C$ ANDs the carry flag with the inverse of a specified bit in the contents of a general register or a memory location and stores the result in the carry flag. The bit number is specified by 3-bit immediate data.
BOR	B	$C \vee (\text{<bit-No.> of <EAd>}) \rightarrow C$ ORs the carry flag with a specified bit in the contents of a general register or a memory location and stores the result in the carry flag. The bit number is specified by 3-bit immediate data.

Instruction	Size	Function
BIOR	B	$C \vee [\sim (\text{<bit-No.> of <EAd>})] \rightarrow C$ ORs the carry flag with the inverse of a specified bit in the contents of a general register or a memory location and stores the result in the carry flag. The bit number is specified by 3-bit immediate data.
BXOR	B	$C \oplus (\text{<bit-No.> of <EAd>}) \rightarrow C$ Exclusive-ORs the carry flag with a specified bit in the contents of a general register or a memory location and stores the result in the carry flag. The bit number is specified by 3-bit immediate data.
BIXOR	B	$C \oplus [\sim (\text{<bit-No.> of <EAd>})] \rightarrow C$ Exclusive-ORs the carry flag with the inverse of a specified bit in the contents of a general register or a memory location and stores the result in the carry flag. The bit number is specified by 3-bit immediate data.
BLD	B	$(\text{<bit-No.> of <EAd>}) \rightarrow C$ Transfers a specified bit in the contents of a general register or a memory location to the carry flag. The bit number is specified by 3-bit immediate data.
BILD	B	$\sim (\text{<bit-No.> of <EAd>}) \rightarrow C$ Transfers the inverse of a specified bit in the contents of a general register or a memory location to the carry flag. The bit number is specified by 3-bit immediate data.
BST	B	$C \rightarrow (\text{<bit-No.> of <EAd>})$ Transfers the carry flag value to a specified bit in the contents of a general register or a memory location. The bit number is specified by 3-bit immediate data.
BSTZ	B	$Z \rightarrow (\text{<bit-No.> of <EAd>})$ Transfers the zero flag value to a specified bit in the contents of a memory location. The bit number is specified by 3-bit immediate data.
BIST	B	$\sim C \rightarrow (\text{<bit-No.> of <EAd>})$ Transfers the inverse of the carry flag value to a specified bit in the contents of a general register or a memory location. The bit number is specified by 3-bit immediate data.

Instruction	Size	Function
BISTZ	B	~ Z → (<bit-No.> of <EAd>) Transfers the inverse of the zero flag value to a specified bit in the contents of a memory location. The bit number is specified by 3-bit immediate data.
BFLD	B	(EAs) (bit field) → Rd Transfers a specified bit field in memory location contents to the lower bits of a specified general register.
BFST	B	Rs → (EAd) (bit field) Transfers the lower bits of a specified general register to a specified bit field in memory location contents.

**Table 2.10 Branch Instructions**

Instruction	Size	Function
BRA/BS BRA/BC	B	Tests a specified bit in memory location contents. If the specified condition is satisfied, execution branches to a specified address.
BSR/BS BSR/BC	B	Tests a specified bit in memory location contents. If the specified condition is satisfied, execution branches to a subroutine at a specified address.
Bcc	—	Branches to a specified address if the specified condition is satisfied.
BRA/S	—	Branches unconditionally to a specified address after executing the next instruction. The next instruction should be a 1-word instruction except for the block transfer and branch instructions.
JMP	—	Branches unconditionally to a specified address.
BSR	—	Branches to a subroutine at a specified address.
JSR	—	Branches to a subroutine at a specified address.
RTS	—	Returns from a subroutine.
RTS/L	—	Returns from a subroutine, restoring data from the stack to multiple general registers.

**Table 2.11 System Control Instructions**

<b>Instruction</b>	<b>Size</b>	<b>Function</b>
TRAPA	—	Starts trap-instruction exception handling.
RTE	—	Returns from an exception-handling routine.
RTE/L	—	Returns from an exception-handling routine, restoring data from the stack to multiple general registers.
SLEEP	—	Causes a transition to a power-down state.
LDC	B/W	#IMM → CCR, (EAs) → CCR, #IMM → EXR, (EAs) → EXR Loads immediate data or the contents of a general register or a memory location to CCR or EXR. Although CCR and EXR are 8-bit registers, word-size transfers are performed between them and memory. The upper 8 bits are valid.
	L	Rs → VBR, Rs → SBR Transfers the general register contents to VBR or SBR.
STC	B/W	CCR → (EAd), EXR → (EAd) Transfers the contents of CCR or EXR to a general register or memory. Although CCR and EXR are 8-bit registers, word-size transfers are performed between them and memory. The upper 8 bits are valid.
	L	VBR → Rd, SBR → Rd Transfers the contents of VBR or SBR to a general register.
ANDC	B	CCR ∧ #IMM → CCR, EXR ∧ #IMM → EXR Logically ANDs the CCR or EXR contents with immediate data.
ORC	B	CCR ∨ #IMM → CCR, EXR ∨ #IMM → EXR Logically ORs the CCR or EXR contents with immediate data.
XORC	B	CCR ⊕ #IMM → CCR, EXR ⊕ #IMM → EXR Logically exclusive-ORs the CCR or EXR contents with immediate data.
NOP	—	PC + 2 → PC Only increments the program counter.

### 2.7.3 Basic Instruction Formats

The H8SX CPU instructions consist of 2-byte (1-word) units. An instruction consists of an operation field (op field), a register field (r field), an effective address extension (EA field), and a condition field (cc).

Figure 2.14 shows examples of instruction formats.

**Figure 2.14 Instruction Formats**

- **Operation Field**  
Indicates the function of the instruction, and specifies the addressing mode and operation to be carried out on the operand. The operation field always includes the first four bits of the instruction. Some instructions have two operation fields.
- **Register Field**  
Specifies a general register. Address registers are specified by 3 bits, data registers by 3 bits or 4 bits. Some instructions have two register fields. Some have no register field.
- **Effective Address Extension**  
8, 16, or 32 bits specifying immediate data, an absolute address, or a displacement.
- **Condition Field**  
Specifies the branch condition of Bcc instructions.

## 2.8 Addressing Modes and Effective Address Calculation

The H8SX CPU supports the 11 addressing modes listed in table 2.12. Each instruction uses a subset of these addressing modes.

Bit manipulation instructions use register direct, register indirect, or absolute addressing mode to specify an operand, and register direct (BSET, BCLR, BNOT, and BTST instructions) or immediate (3-bit) addressing mode to specify a bit number in the operand.

**Table 2.12 Addressing Modes**

No.	Addressing Mode	Symbol
1	Register direct	Rn
2	Register indirect	@ERn
3	Register indirect with displacement	@(d:2,ERn)/@(d:16,ERn)/@(d:32,ERn)
4	Index register indirect with displacement	@(d:16, RnL.B)/@(d:16,Rn.W)/@(d:16,ERn.L) @(d:32, RnL.B)/@(d:32,Rn.W)/@(d:32,ERn.L)
5	Register indirect with post-increment	@ERn+
	Register indirect with pre-decrement	@-ERn
	Register indirect with pre-increment	@+ERn
	Register indirect with post-decrement	@ERn-
6	Absolute address	@aa:8/@aa:16/@aa:24/@aa:32
7	Immediate	#xx:3/#xx:4/#xx:8/#xx:16/#xx:32
8	Program-counter relative	@(d:8,PC)/@(d:16,PC)
9	Program-counter relative with index register	@(RnL.B,PC)/@(Rn.W,PC)/@(ERn.L,PC)
10	Memory indirect	@@aa:8
11	Extended memory indirect	@@vec:7

### 2.8.1 Register Direct—Rn

The operand value is the contents of an 8-, 16-, or 32-bit general register which is specified by the register field in the instruction code.

R0H to R7H and R0L to R7L can be specified as 8-bit registers.

R0 to R7 and E0 to E7 can be specified as 16-bit registers.

ER0 to ER7 can be specified as 32-bit registers.

### 2.8.2 Register Indirect—@ERn

The operand value is the contents of the memory location which is pointed to by the contents of an address register (ERn). ERn is specified by the register field of the instruction code.

In advanced mode, if this addressing mode is used in a branch instruction, the lower 24 bits are valid and the upper 8 bits are all assumed to be 0 (H'00).

### 2.8.3 Register Indirect with Displacement—@(d:2, ERn), @(d:16, ERn), or @(d:32, ERn)

The operand value is the contents of a memory location which is pointed to by the sum of the contents of an address register (ERn) and a 16- or 32-bit displacement. ERn is specified by the register field of the instruction code. The displacement is included in the instruction code and the 16-bit displacement is sign-extended when added to ERn.

This addressing mode has a short format (@(d:2, ERn)). The short format can be used when the displacement is 1, 2, or 3 and the operand is byte data, when the displacement is 2, 4, or 6 and the operand is word data, or when the displacement is 4, 8, or 12 and the operand is longword data.

### 2.8.4 Index Register Indirect with Displacement— $@(d:16,RnL.B)$ , $@(d:32,RnL.B)$ , $@(d:16,Rn.W)$ , $@(d:32,Rn.W)$ , $@(d:16,ERn.L)$ , or $@(d:32,ERn.L)$

The operand value is the contents of a memory location which is pointed to by the sum of the following operation result and a 16- or 32-bit displacement: a specified bits of the contents of an address register (RnL, Rn, ERn) specified by the register field in the instruction code are zero-extended to 32-bit data and multiplied by 1, 2, or 4. The displacement is included in the instruction code and the 16-bit displacement is sign-extended when added to ERn. If the operand is byte data, ERn is multiplied by 1. If the operand is word or longword data, ERn is multiplied by 2 or 4, respectively.

### 2.8.5 Register Indirect with Post-Increment, Pre-Decrement, Pre-Increment, or Post-Decrement— $@ERn+$ , $@-ERn$ , $@+ERn$ , or $@ERn-$

#### (1) Register indirect with post-increment— $@ERn+$

The operand value is the contents of a memory location which is pointed to by the contents of an address register (ERn). ERn is specified by the register field of the instruction code. After the memory location is accessed, 1, 2, or 4 is added to the address register contents and the sum is stored in the address register. The value added is 1 for byte access, 2 for word access, or 4 for longword access.

#### (2) Register indirect with pre-decrement— $@-ERn$

The operand value is the contents of a memory location which is pointed to by the following operation result: the value 1, 2, or 4 is subtracted from the contents of an address register (ERn). ERn is specified by the register field of the instruction code. After that, the operand value is stored in the address register. The value subtracted is 1 for byte access, 2 for word access, or 4 for longword access.

#### (3) Register indirect with pre-increment— $@+ERn$

The operand value is the contents of a memory location which is pointed to by the following operation result: the value 1, 2, or 4 is added to the contents of an address register (ERn). ERn is specified by the register field of the instruction code. After that, the operand value is stored in the address register. The value added is 1 for byte access, 2 for word access, or 4 for longword access.

#### (4) Register indirect with post-decrement—@ERn-

The operand value is the contents of a memory location which is pointed to by the contents of an address register (ERn). ERn is specified by the register field of the instruction code. After the memory location is accessed, 1, 2, or 4 is subtracted from the address register contents and the remainder is stored in the address register. The value subtracted is 1 for byte access, 2 for word access, or 4 for longword access.

If the contents of a general register which is also used as an address register is written to memory using this addressing mode, data to be written is the contents of the address register after calculating an effective address.

#### 2.8.6 Absolute Address—@aa:8, @aa:16, @aa:24, or @aa:32

The operand value is the contents of a memory location which is pointed to by an absolute address included in the instruction code.

There are 8-bit (@aa:8), 16-bit (@aa:16), 24-bit (@aa:24), and 32-bit (@aa:32) absolute addresses.

To access the data area, the absolute address of 8 bits (@aa:8), 16 bits (@aa:16), or 32 bits (@aa:32) is used. For an 8-bit absolute address, the upper 24 bits are specified by SBR. For a 16-bit absolute address, the upper 16 bits are sign-extended. A 32-bit absolute address can access the entire address space.

To access the program area, the absolute address of 24 bits (@aa:24) or 32 bits (@aa:32) is used. For a 24-bit absolute address, the upper 8 bits are all assumed to be 0 (H'00).

Table 2.13 shows the accessible absolute address ranges.

**Table 2.13 Absolute Address Access Ranges**

<b>Absolute Address</b>		<b>Normal Mode</b>	<b>Middle Mode</b>	<b>Advanced Mode</b>	<b>Maximum Mode</b>
Data area	8 bits (@aa:8)	A consecutive 256-byte area (the upper address is set in SBR)			
	16 bits (@aa:16)	H'0000 to H'FFFF	H'000000 to H'007FFF,	H'00000000 to H'00007FFF, H'FFFF8000 to H'FFFFFFFF	
	32 bits (@aa:32)		H'FF8000 to H'FFFFFF	H'00000000 to H'FFFFFFFF	
Program area	24 bits (@aa:24)		H'000000 to H'FFFFFF	H'00000000 to H'00FFFFFF	
	32 bits (@aa:32)			H'00000000 to H'00FFFFFF	H'00000000 to H'FFFFFFFF

### 2.8.7 Immediate—#xx

The operand value is 8-bit (#xx:8), 16-bit (#xx:16), or 32-bit (#xx:32) data included in the instruction code.

This addressing mode has short formats in which 3- or 4-bit immediate data can be used.

When the size of immediate data is less than that of the destination operand value (byte, word, or longword) the immediate data is zero-extended.

The ADDS, SUBS, INC, and DEC instructions contain immediate data implicitly. Some bit manipulation instructions contain 3-bit immediate data in the instruction code, for specifying a bit number. The BFLD and BFST instructions contain 8-bit immediate data in the instruction code, for specifying a bit field. The TRAPA instruction contains 2-bit immediate data in the instruction code, for specifying a vector address.

### 2.8.8 Program-Counter Relative—@(d:8, PC) or @(d:16, PC)

This mode is used in the Bcc and BSR instructions. The operand value is a 32-bit branch address, which is the sum of an 8- or 16-bit displacement in the instruction code and the 32-bit address of the PC contents. The 8-bit or 16-bit displacement is sign-extended to 32 bits when added to the PC contents. The PC contents to which the displacement is added is the address of the first byte of the next instruction, so the possible branching range is  $-126$  to  $+128$  bytes ( $-63$  to  $+64$  words) or  $-32766$  to  $+32768$  bytes ( $-16383$  to  $+16384$  words) from the branch instruction. The resulting value should be an even number. In advanced mode, only the lower 24 bits of this branch address are valid; the upper 8 bits are all assumed to be 0 (H'00).

### 2.8.9 Program-Counter Relative with Index Register— @(RnL.B, PC), @(Rn.W, PC), or @(ERn.L, PC)

This mode is used in the Bcc and BSR instructions. The operand value is a 32-bit branch address, which is the sum of the following operation result and the 32-bit address of the PC contents: the contents of an address register specified by the register field in the instruction code (RnL, Rn, or ERn) is zero-extended and multiplied by 2. The PC contents to which the displacement is added is the address of the first byte of the next instruction. In advanced mode, only the lower 24 bits of this branch address are valid; the upper 8 bits are all assumed to be 0 (H'00).

### 2.8.10 Memory Indirect—@@aa:8

This mode can be used by the JMP and JSR instructions. The operand value is a branch address, which is the contents of a memory location pointed to by an 8-bit absolute address in the instruction code.

The upper bits of an 8-bit absolute address are all assumed to be 0, so the address range is 0 to 255 (H'0000 to H'00FF in normal mode, H'000000 to H'0000FF in other modes).

In normal mode, the memory location is pointed to by word-size data and the branch address is 16 bits long. In other modes, the memory location is pointed to by longword-size data. In middle or advanced mode, the first byte of the longword-size data is assumed to be all 0 (H'00).

Note that the top part of the address range is also used as the exception handling vector area. A vector address of an exception handling other than a reset or a CPU address error can be changed by VBR.

Figure 2.15 shows an example of specification of a branch address using this addressing mode.

**Figure 2.15 Branch Address Specification in Memory Indirect Mode**

### 2.8.11 Extended Memory Indirect—@@vec:7

This mode can be used by the JMP and JSR instructions. The operand value is a branch address, which is the contents of a memory location pointed to by the following operation result: the sum of 7-bit data in the instruction code and the value of H'80 is multiplied by 2 or 4.

The address range to store a branch address is H'0100 to H'01FF in normal mode and H'000200 to H'0003FF in other modes. In assembler notation, an address to store a branch address is specified.

In normal mode, the memory location is pointed to by word-size data and the branch address is 16 bits long. In other modes, the memory location is pointed to by longword-size data. In middle or advanced mode, the first byte of the longword-size data is assumed to be all 0 (H'00).

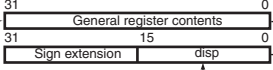

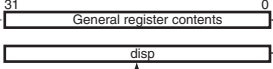

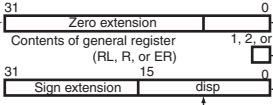

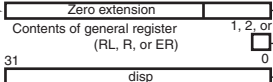

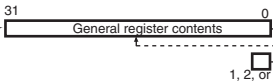

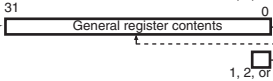

### 2.8.12 Effective Address Calculation

Tables 2.14 and 2.15 show how effective addresses are calculated in each addressing mode. The lower bits of the effective address are valid and the upper bits are ignored (zero extended or sign extended) according to the CPU operating mode.

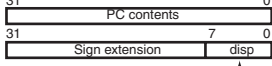

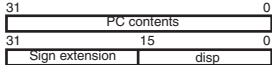

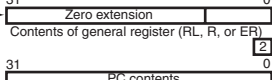

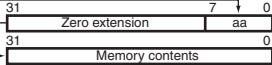

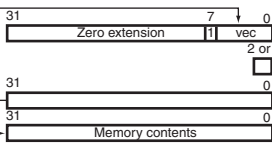

The valid bits in middle mode are as follows:

- The lower 16 bits of the effective address are valid and the upper 16 bits are sign-extended for the transfer and operation instructions.
- The lower 24 bits of the effective address are valid and the upper eight bits are zero-extended for the branch instructions.

**Table 2.14 Effective Address Calculation for Transfer and Operation Instructions**

No.	Addressing Mode and Instruction Format	Effective Address Calculation	Effective Address (EA)
1	Immediate 		
2	Register direct 		
3	Register indirect 		
4	Register indirect with 16-bit displacement 		
	Register indirect with 32-bit displacement 		
5	Index register indirect with 16-bit displacement 		
	Index register indirect with 32-bit displacement 		
6	Register indirect with post-increment or post-decrement 		
	Register indirect with pre-increment or pre-decrement 		
7	8-bit absolute address 		
	16-bit absolute address 		
	32-bit absolute address 		

**Table 2.15 Effective Address Calculation for Branch Instructions**

No.	Addressing Mode and Instruction Format	Effective Address Calculation	Effective Address (EA)
1	Register indirect 		
2	Program-counter relative with 8-bit displacement 		
	Program-counter relative with 16-bit displacement 		
3	Program-counter relative with index register 		
4	24-bit absolute address 		
	32-bit absolute address 		
5	Memory indirect 		
6	Extended memory indirect 		

### 2.8.13 MOVA Instruction

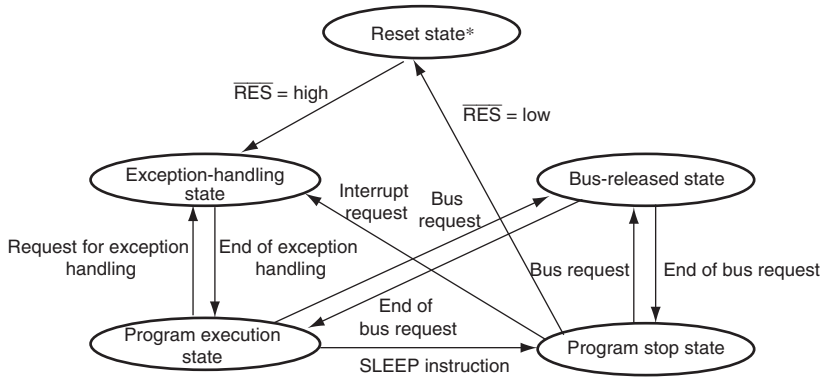

The MOVA instruction stores the effective address in a general register.

1. Firstly, data is obtained by the addressing mode shown in item 2 of table 2.14.
2. Next, the effective address is calculated using the obtained data as the index by the addressing mode shown in item 5 of table 2.14. The obtained data is used instead of the general register. The result is stored in a general register. For details, see H8SX Family Software Manual.

## 2.9 Processing States

The H8SX CPU has five main processing states: the reset state, exception-handling state, program execution state, bus-released state, and program stop state. Figure 2.16 indicates the state transitions.

- **Reset state**  
In this state the CPU and internal peripheral modules are all initialized and stopped. When the  $\overline{\text{RES}}$  input goes low, all current processing stops and the CPU enters the reset state. All interrupts are masked in the reset state. Reset exception handling starts when the  $\overline{\text{RES}}$  signal changes from low to high. The reset state can also be entered by a watchdog timer overflow. For details, refer to section 4, Exception Handling.
- **Exception-handling state**  
The exception-handling state is a transient state that occurs when the CPU alters the normal processing flow due to activation of an exception source, such as, a reset, trace, interrupt, or trap instruction. The CPU fetches a start address (vector) from the exception handling vector table and branches to that address. For further details, refer to section 4, Exception Handling.
- **Program execution state**  
In this state the CPU executes program instructions in sequence.
- **Bus-released state**  
In this state, the bus has been released in response to a bus request from the DMA controller (DMAC). While the bus is released, the CPU halts operations.
- **Program stop state**  
This is a power-down state in which the CPU stops operating. The program stop state occurs when a SLEEP instruction is executed or the CPU enters software standby mode. For details, refer to section 19, Power-Down Modes.

Note: \* A transition to the reset state occurs whenever the  $\overline{\text{RES}}$  signal goes low. A transition can also be made to the reset state when the watchdog timer overflows.

**Figure 2.16 State Transitions**

## Section 3 MCU Operating Modes

### 3.1 Operating Mode Selection

This LSI has three operating modes (modes 1 to 3). The operating mode is selected by the setting of mode pins (MD1 and MD0). Table 3.1 lists MCU operating mode settings.

In this LSI, advanced mode for the CPU operating mode and 16-Mbyte address space are available. LSI initiation mode can be selected from boot mode and user boot mode for programming/erasing the flash memory and single chip initiation mode.

**Table 3.1 MCU Operating Mode Settings**

MCU Operating Mode	MD1	MD0	CPU Operating Mode	Address Space	Description	On-Chip ROM
1	0	1	Advanced	16 Mbytes	User boot mode	Enabled
2	1	0			Boot mode	Enabled
3	1	1			Single chip initiation mode	Enabled

In mode 1 and mode 2, which are user boot mode and boot mode, the flash memory can be programmed and erased. For details on user boot mode and boot mode, see section 17, Flash Memory (0.18- $\mu$ m F-ZTAT Version).

In mode 3, this LSI operates in single chip mode.

## 3.2 Register Descriptions

The following registers are related to the operating mode setting.

- Mode control register (MDCR)
- System control register (SYSCR)

### 3.2.1 Mode Control Register (MDCR)

MDCR indicates the current operating mode. When MDCR is read, the states of signals input on pins MD1 and MD0 are latched. The latch is released by a reset.

Bit	15	14	13	12	11	10	9	8

### 3.2.2 System Control Register (SYSCR)

SYSCR controls MAC saturation operation and selects enables/disables the on-chip RAM and the flash memory control registers.

Bit	15	14	13	12	11	10	9	8
Bit Name	—	—	MACS	—	—	—	—	RAME
Initial Value	1	1	0	1	0	1	0	1
R/W	R	R	R/W	R	R/W	R/W	R/W	R/W

Bit	7	6	5	4	3	2	1	0
Bit Name	FLSHE	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	—	All 1	R	Reserved These are read-only bits and cannot be modified.
13	MACS	0	R/W	MAC Saturation Operation Control Selects either saturation operation or non-saturation operation for the MAC instruction. 0: MAC instruction is non-saturation operation 1: MAC instruction is saturation operation
12	—	1	R	Reserved This is a read-only bit and cannot be modified.
11	—	0	R/W	Reserved This bit is always read as 0. The write value should always be 0.
10	—	1	R/W	Reserved This bit is always read as 1. The write value should always be 1.
9	—	0	R/W	Reserved This bit is always read as 0. The write value should always be 0.
8	RAME	1	R/W	RAM Enable Enables or disables the on-chip RAM. This bit is initialized when the reset state is released. Do not write 0 during access to the on-chip RAM. 0: On-chip RAM disabled 1: On-chip RAM enabled
7	FLSHE	0	R/W	Flash Memory Control Register Enable Controls accesses to the flash memory control registers. Setting this bit to 1 enables to read from and write to the flash memory control registers. Clearing this bit to 0 disables the flash memory control registers. At this time, the contents of the flash memory control registers are retained. The write value should be 0 when the LSI is not the flash memory version. 0: Disables the flash memory control registers 1: Enables the flash memory control registers
6 to 2	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	—	All 1	R/W	Reserved This bit is always read as 1. The write value should always be 1.

## **3.3 Operating Mode Descriptions**

### **3.3.1 Mode 1**

Mode 1 is the user boot mode for the flash memory. The operations are the same as that in mode 3 other than programming/erasing the flash memory.

### **3.3.2 Mode 2**

Mode 2 is the boot mode for the flash memory. The operations are the same as that in mode 3 other than programming/erasing the flash memory.

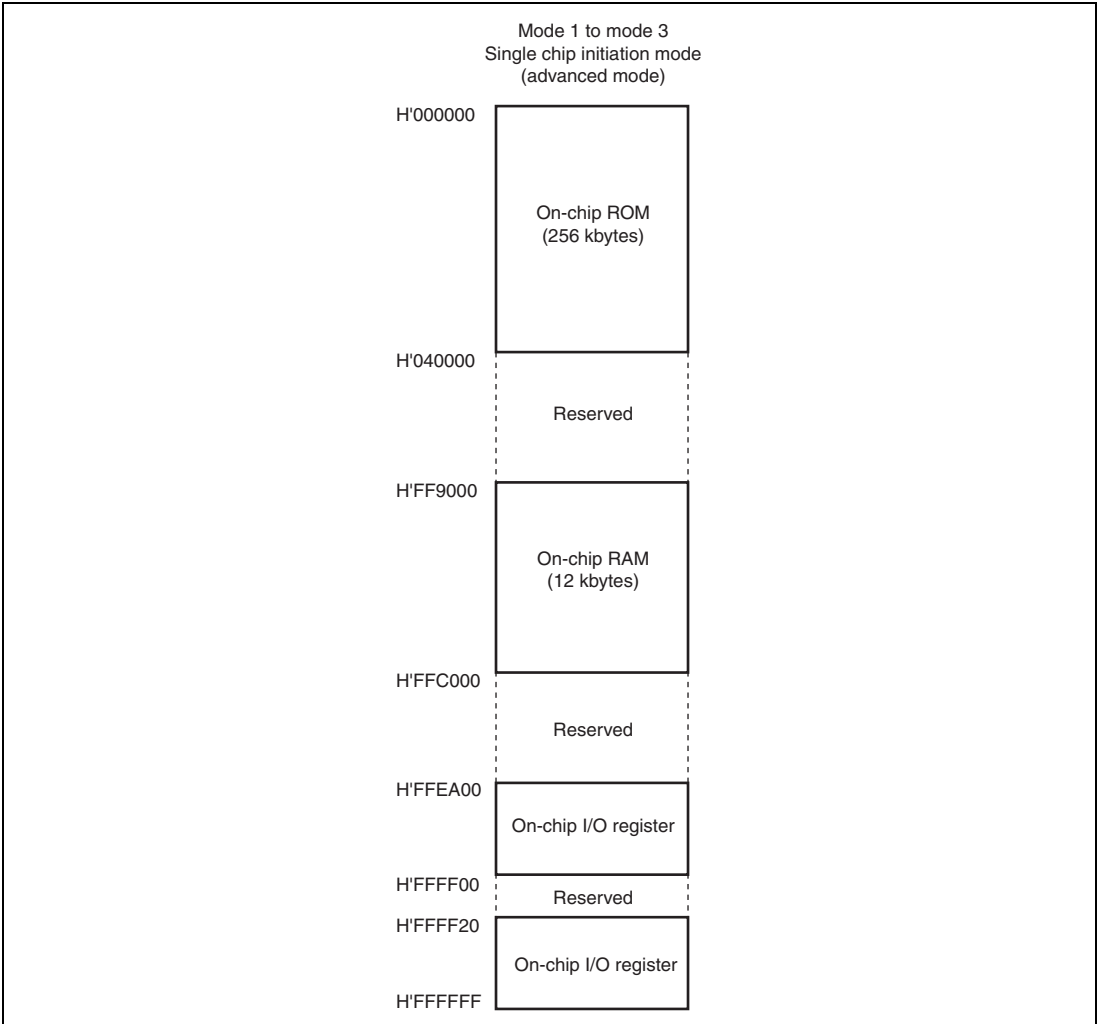

### **3.3.3 Mode 3**

Mode 3 is advanced mode in which the address space is 16 Mbytes, and single-chip mode with the on-chip ROM enabled.

## 3.4 Address Map

### 3.4.1 Address Map (Advanced Mode)

Figure 3.1 shows the address map.

**Figure 3.1 Address Map (Advanced Mode)**

## Section 4 Exception Handling

### 4.1 Exception Handling Types and Priority

As table 4.1 indicates, exception handling is caused by a reset, a trace, an address error, an interrupt, a trap instruction, and illegal instructions (general illegal instruction and slot illegal instruction). Exception handling is prioritized as shown in table 4.1. If two or more exceptions occur simultaneously, they are accepted and processed in order of priority. Exception sources, the stack structure, and operation of the CPU vary depending on the interrupt control mode. For details on the interrupt control mode, see section 5, Interrupt Controller.

**Table 4.1 Exception Types and Priority**

Priority	Exception Type	Exception Handling Start Timing
High  Low	Reset	Exception handling starts at the timing of level change from low to high on the $\overline{\text{RES}}$ pin, or when the watchdog timer overflows. The CPU enters the reset state when the $\overline{\text{RES}}$ pin is low.
	Illegal instruction	Exception handling starts when an undefined code is executed.
	Trace* <sup>1</sup>	Exception handling starts after execution of the current instruction or exception handling, if the trace (T) bit in EXR is set to 1.
	Address error	After an address error occurs, the exception handling starts on completion of the current instruction execution.
	Interrupt	Exception handling starts after execution of the current instruction or exception handling, if an interrupt request has occurred.* <sup>2</sup>
	Trap instruction* <sup>3</sup>	Exception handling starts by execution of a trap instruction (TRAPA).

- Notes:
- Traces are enabled only in interrupt control mode 2. Trace exception handling is not executed after execution of an RTE instruction.
  - Interrupt detection is not performed on completion of ANDC, ORC, XORC, or LDC instruction execution, or on completion of reset exception handling.
  - Trap instruction exception handling requests are accepted at all times in the program execution state.

## 4.2 Exception Sources and Exception Handling Vector Table

Different vector table address offsets are assigned to different exception sources. The vector table addresses are calculated from the contents of the vector base register (VBR) and vector table address offset of the vector number. The start address of the exception service routine is fetched from the exception handling vector table indicated by this vector table address.

Table 4.2 shows the correspondence between the exception sources and vector table address offsets. Table 4.3 shows the calculation method of exception handling vector table addresses.

Since the usable modes differ depending on the product, for details on the available modes, see section 3, MCU Operating Modes.

**Table 4.2 Exception Handling Vector Table**

Exception Source	Vector Number	Vector Table Address Offset* <sup>1</sup>		
		Normal Mode* <sup>2</sup>	Advanced, Middle, Maximum Modes	
Reset	0	H'0000 to H'0001	H'0000 to H'0003	
Reserved for system use	1	H'0002 to H'0003	H'0004 to H'0007	
	2	H'0004 to H'0005	H'0008 to H'000B	
	3	H'0006 to H'0007	H'000C to H'000F	
Illegal instruction	4	H'0008 to H'0009	H'0010 to H'0013	
Trace	5	H'000A to H'000B	H'0014 to H'0017	
Reserved for system use	6	H'000C to H'000D	H'0018 to H'001B	
Interrupt (NMI)	7	H'000E to H'000F	H'001C to H'001F	
Trap instruction	(#0)	8	H'0010 to H'0011	H'0020 to H'0023
	(#1)	9	H'0012 to H'0013	H'0024 to H'0027
	(#2)	10	H'0014 to H'0015	H'0028 to H'002B
	(#3)	11	H'0016 to H'0017	H'002C to H'002F
CPU address error	12	H'0018 to H'0019	H'0030 to H'0033	
DMA address error* <sup>3</sup>	13	H'001A to H'001B	H'0034 to H'0037	
Reserved for system use	14	H'001C to H'001D	H'0038 to H'003B	
	63	H'007E to H'007F	H'00FC to H'00FF	

Exception Source	Vector Number	Vector Table Address Offset* <sup>1</sup>		
		Normal Mode* <sup>2</sup>	Advanced, Middle, Maximum Modes	
External interrupt	IRQ0	64	H'0080 to H'0081	H'0100 to H'0103
	IRQ1	65	H'0082 to H'0083	H'0104 to H'0107
	IRQ2	66	H'0084 to H'0085	H'0108 to H'010B
	IRQ3	67	H'0086 to H'0087	H'010C to H'010F
	IRQ4	68	H'0088 to H'0089	H'0110 to H'0113
	IRQ5	69	H'008A to H'008B	H'0114 to H'0117
	IRQ6	70	H'008C to H'008D	H'0118 to H'011B
	IRQ7	71	H'008E to H'008F	H'011C to H'011F
	IRQ8	72	H'0090 to H'0091	H'0120 to H'0123
	IRQ9	73	H'0092 to H'0093	H'0124 to H'0127
	IRQ10	74	H'0094 to H'0095	H'0128 to H'012B
	IRQ11	75	H'0096 to H'0097	H'012C to H'012F
	IRQ12	76	H'0098 to H'0099	H'0130 to H'0133
	IRQ13	77	H'009A to H'009B	H'0134 to H'0137
IRQ14	78	H'009C to H'009D	H'0138 to H'013B	
Reserved for system use	79	H'009E to H'009F	H'013C to H'013F	
	80	H'00A0 to H'00A1	H'0140 to H'0143	
Internal interrupt* <sup>4</sup>	81	H'00A2 to H'00A3	H'0144 to H'0147	
	255	H'01FE to H'01FF	H'03FC to H'03FF	

- Notes:
1. Lower 16 bits of the address.
  2. Not available in this LSI.
  3. A DMA address error is generated within the DMAC.
  4. For details on the interrupt vector table, see section 5.5, Interrupt Exception Handling Vector Table.

**Table 4.3 Calculation Method of Exception Handling Vector Table Address**

Exception Source	Calculation Method of Vector Table Address
Reset, CPU address error	Vector table address = (vector table address offset)
Other than above	Vector table address = VBR + (vector table address offset)

[Legend]

VBR: Vector base register

Vector table address offset: See table 4.2.

## 4.3 Reset

A reset has priority over any other exception. When the  $\overline{\text{RES}}$  pin goes low, all processing halts and this LSI enters the reset state. To ensure that this LSI is reset, hold the  $\overline{\text{RES}}$  pin low for at least 20 ms when the power is turned on. When operation is in progress, hold the  $\overline{\text{RES}}$  pin low for at least 20 cycles.

The chip can also be reset by overflow of the watchdog timer. For details, see section 11, Watchdog Timer (WDT).

A reset initializes the internal state of the CPU and the registers of the on-chip peripheral modules. The interrupt control mode is 0 immediately after a reset.

### 4.3.1 Reset Exception Handling

When the  $\overline{\text{RES}}$  pin goes high after being held low for the necessary time, this LSI starts reset exception handling as follows:

1. The internal state of the CPU and the registers of the on-chip peripheral modules are initialized, VBR is cleared to H'00000000, the T bit is cleared to 0 in EXR, and the I bits are set to 1 in EXR and CCR.
2. The reset exception handling vector address is read and transferred to the PC, and program execution starts from the address indicated by the PC.

Figure 4.1 shows an example of the reset sequence.

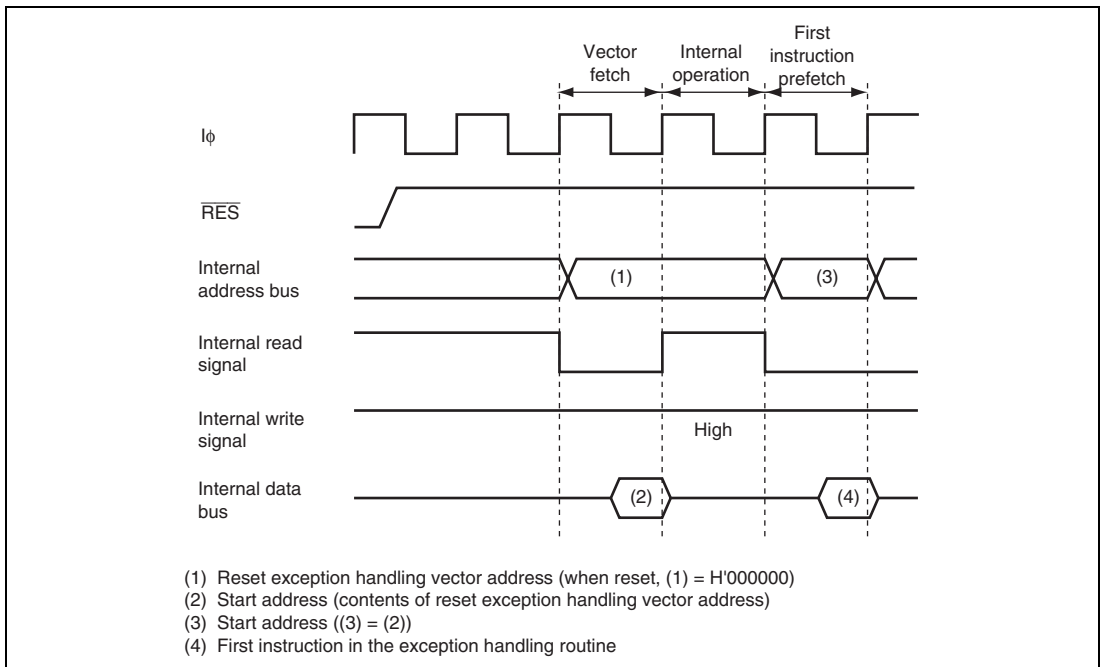

### 4.3.2 Interrupts after Reset

If an interrupt is accepted after a reset but before the stack pointer (SP) is initialized, the PC and CCR will not be saved correctly, leading to a program crash. To prevent this, all interrupt requests, including NMI, are disabled immediately after a reset. Since the first instruction of a program is always executed immediately after the reset state ends, make sure that this instruction initializes the stack pointer (example: `MOV.L #xx: 32, SP`).

### 4.3.3 On-Chip Peripheral Functions after Reset Release

After the reset state is released, MSTPCRA, MSTPCRB, and MSTPCRC are initialized to H'0FFF, H'FFFF, and H'FF00 respectively, and all modules except the DMAC enter module stop mode.

Consequently, on-chip peripheral module registers cannot be read from or written to. Register reading and writing is enabled when module stop mode is canceled.

**Figure 4.1 Reset Sequence (On-Chip ROM Enabled Advanced Mode)**

## 4.4 Traces

Traces are enabled in interrupt control mode 2. Trace mode is not activated in interrupt control mode 0, irrespective of the state of the T bit. Before changing interrupt control modes, the T bit must be cleared to 0. For details on interrupt control modes, see section 5, Interrupt Controller.

If the T bit in EXR is set to 1, trace mode is activated. In trace mode, a trace exception occurs on completion of each instruction. Trace mode is not affected by interrupt masking by CCR. Table 4.4 shows the state of CCR and EXR after execution of trace exception handling. Trace mode is canceled by clearing the T bit in EXR to 0 during the trace exception handling. However, the T bit saved on the stack retains its value of 1, and when control is returned from the trace exception handling routine by the RTE instruction, trace mode resumes. Trace exception handling is not carried out after execution of the RTE instruction.

Interrupts are accepted even within the trace exception handling routine.

**Table 4.4 Status of CCR and EXR after Trace Exception Handling**

Interrupt Control Mode	CCR			EXR	
	I	UI	I2 to I0	T	
0	Trace exception handling cannot be used.				
2	1	—	—	0	

[Legend]

- 1: Set to 1
- 0: Cleared to 0
- : Retains the previous value.

## 4.5 Address Error

### 4.5.1 Address Error Source

Instruction fetch, stack operation, data read/write, and single-address transfer shown in table 4.5 may cause an address error.

**Table 4.5 Bus Cycle and Address Error**

Bus Cycle			
Type	Bus Master	Description	Address Error
Instruction fetch	CPU	Fetches instructions from even addresses	No (normal)
		Fetches instructions from odd addresses	Occurs
		Fetches instructions from areas other than on-chip peripheral module space* <sup>1</sup>	No (normal)
		Fetches instructions from on-chip peripheral module space* <sup>1</sup>	Occurs
		Fetches instructions from external memory space in single-chip mode	Occurs
		Fetches instructions from access reserved area.* <sup>2</sup>	Occurs
Stack operation	CPU	Accesses stack when the stack pointer value is even address	No (normal)
		Accesses stack when the stack pointer value is odd	Occurs
Data read/write	CPU	Accesses word data from even addresses	No (normal)
		Accesses word data from odd addresses	No (normal)
		Accesses external memory space in single-chip mode	Occurs
		Accesses to reserved area* <sup>2</sup>	Occurs
Data read/write	DMAC	Accesses word data from even addresses	No (normal)
		Accesses word data from odd addresses	No (normal)
		Accesses external memory space in single-chip mode	Occurs
		Accesses to reserved area* <sup>2</sup>	Occurs

### Bus Cycle

Type	Bus Master	Description	Address Error
Single address transfer	DMAC	In single address transfer, the device to be accessed with an address is in the external memory space	No (normal)
		In single address transfer, the device to be accessed with an address is not in the external memory space	Occurs

- Notes:
1. For on-chip peripheral module space, see section 6, Bus Controller (BSC).
  2. For the access reserved area, refer to figure 3.1 in section 3.4, Address Map. An address error will not occur when the reserved area from H'FF8000 to H'FF8FFF is accessed.

#### 4.5.2 Address Error Exception Handling

When an address error occurs, address error exception handling starts after the bus cycle causing the address error ends and current instruction execution completes. The address error exception handling is as follows:

1. The contents of PC, CCR, and EXR are saved in the stack.
2. The interrupt mask bit is updated and the T bit is cleared to 0.
3. An exception handling vector table address corresponding to the address error is generated, the start address of the exception service routine is loaded from the vector table to PC, and program execution starts from that address.

Even though an address error occurs during a transition to an address error exception handling, the address error is not accepted. This prevents an address error from occurring due to stacking for exception handling, thereby preventing infinitive stacking.

If the SP contents are not a multiple of 2 when an address error exception handling occurs, the stacked values (PC, CCR, and EXR) are undefined.

When an address error occurs, the following is performed to halt the DMAC.

- ERRF bit in DMDR\_0 of the DMAC is set to 1
- DTE bits for all the channels of the DMAC are cleared to 0 and the DMAC is forced to halt

Table 4.6 shows the states of CCR and EXR after the address error exception handling.

**Table 4.6 States of CCR and EXR after Address Error Exception Handling**

Interrupt Control Mode	CCR			EXR
	I	UI	T	I2 to I0
0	1	—	—	—
2	1	—	0	7

[Legend]

- 1: Set to 1.
- 0: Cleared to 0.
- : Retains the previous value.

## 4.6 Interrupts

### 4.6.1 Interrupt Sources

Interrupt sources are NMI, IRQ0 to IRQ14, and on-chip peripheral modules, as shown in table 4.7.

**Table 4.7 Interrupt Sources**

Type	Source	Number of Sources
NMI	NMI pin (external input)	1
IRQ0 to IRQ14	Pins $\overline{\text{IRQ0}}$ to $\overline{\text{IRQ14}}$ (external input)	15
On-chip peripheral module	Watchdog timer (WDT)	1
	A/D converter	2
	16-bit timer pulse unit (TPU)	$52^{*1}/26^{*2}$
	DMA controller (DMAC)	8
	Serial communications interface (SCI)	8
	Synchronous serial communication unit (SSU)	9
	Controller area network (RCAN-ET)	4

- Notes: 1. The number of interrupts for the H8SX/1527R  
 2. The number of interrupts for the H8SX/1525R

Different vector numbers and vector table offsets are assigned to different interrupt sources. For vector number and vector table offset, refer to table 5.2 in section 5.5, Interrupt Exception Handling Vector Table.

## 4.6.2 Interrupt Exception Handling

Interrupts are controlled by the interrupt controller. The interrupt controller has two interrupt control modes and can assign interrupts other than NMI to eight priority/mask levels to enable multiple-interrupt control. The source to start interrupt exception handling and the vector address differ depending on the product. For details, refer to section 5, Interrupt Controller.

The interrupt exception handling is as follows:

1. The contents of PC, CCR, and EXR are saved in the stack.
2. The interrupt mask bit is updated and the T bit is cleared to 0.
3. An exception handling vector table address corresponding to the interrupt source is generated, the start address of the exception service routine is loaded from the vector table to PC, and program execution starts from that address.

## 4.7 Instruction Exception Handling

There are two types of instructions that cause exception handling: trap instruction and illegal instructions.

### 4.7.1 Trap Instruction

Trap instruction exception handling starts when a TRAPA instruction is executed. Trap instruction exception handling can be executed at all times in the program execution state. The trap instruction exception handling is as follows:

1. The contents of PC, CCR, and EXR are saved in the stack.
2. The interrupt mask bit is updated and the T bit is cleared to 0.
3. An exception handling vector table address corresponding to the vector number specified in the TRAPA instruction is generated, the start address of the exception service routine is loaded from the vector table to PC, and program execution starts from that address.

A start address is read from the vector table corresponding to a vector number from 0 to 3, as specified in the instruction code.

Table 4.8 shows the state of CCR and EXR after execution of trap instruction exception handling.

**Table 4.8 Status of CCR and EXR after Trap Instruction Exception Handling**

Interrupt Control Mode	CCR		EXR	
	I	UI	T	I2 to I0
0	1	—	—	—
2	1	—	0	—

[Legend]

- 1: Set to 1
- 0: Cleared to 0
- : Retains the previous value.

### 4.7.2 Exception Handling by Illegal Instruction

There are two illegal instructions: general illegal instruction and slot illegal instruction.

The exception handling by the general illegal instruction starts when an undefined code is decoded.

The exception handling by the slot illegal instruction starts when the following instruction which is placed in a delay slot (immediately after a delayed branch instruction) is executed: an instruction which consists of two words or more or which changes the contents of PC.

The general illegal and slot illegal instructions are always executable in the program execution state.

The exception handling for the general illegal and a slot illegal instructions is as follows:

1. The contents of PC, CCR, and EXR are saved in the stack.
2. The interrupt mask bit is updated and the T bit is cleared to 0.
3. An exception handling vector table address corresponding to the occurred exception is generated, the start address of the exception service routine is loaded from the vector table to PC, and program execution starts from that address.

Table 4.9 shows the state of CCR and EXR after execution of illegal instruction exception handling.

**Table 4.9 Status of CCR and EXR after Illegal Instruction Exception Handling**

Interrupt Control Mode	CCR		EXR	
	I	UI	T	I2 to I0
0	1	—	—	—
2	1	—	0	—

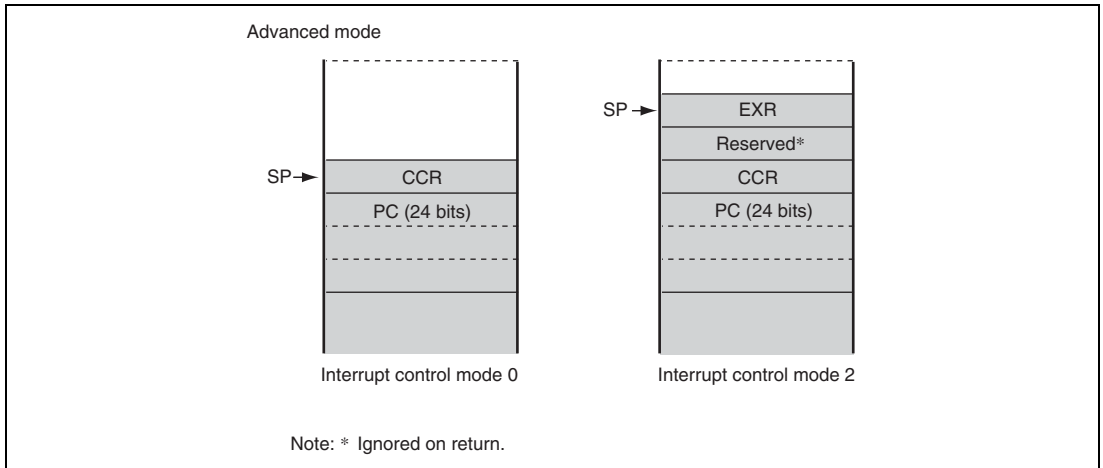

[Legend]

- 1: Set to 1
- 0: Cleared to 0
- : Retains the previous value.

## 4.8 Stack Status after Exception Handling

Figure 4.2 shows the stack after completion of exception handling.

**Figure 4.2 Stack Status after Exception Handling**

## 4.9 Usage Note

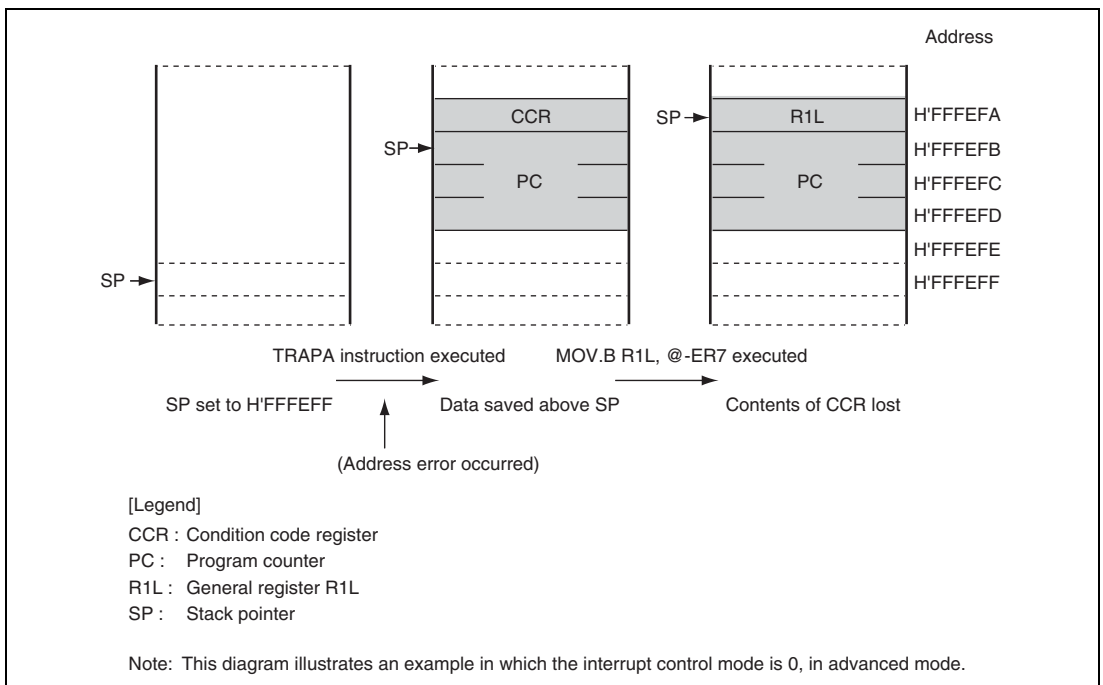

When performing stack-manipulating access, this LSI assumes that the lowest address bit is 0. The stack should always be accessed by a word transfer instruction or a longword transfer instruction, and the value of the stack pointer (SP: ER7) should always be kept even. Use the following instructions to save registers:

- PUSH.W Rn (or MOV.W Rn, @-SP)
- PUSH.L ERn (or MOV.L ERn, @-SP)

Use the following instructions to restore registers:

- POP.W Rn (or MOV.W @SP+, Rn)
- POP.L ERn (or MOV.L @SP+, ERn)

Performing stack manipulation while SP is set to an odd value leads to an address error. Figure 4.3 shows an example of operation when the SP value is odd.

**Figure 4.3 Operation when SP Value Is Odd**

## Section 5 Interrupt Controller

### 5.1 Features

- Two interrupt control modes

Any of two interrupt control modes can be set by means of bits INTM1 and INTM0 in the interrupt control register (INTCR).
- Priority can be assigned by the interrupt priority register (IPR)

IPR provides for setting interrupt priority. Eight levels can be set for each module for all interrupts except for the interrupt requests listed below. The following six interrupt requests are given priority of 8, therefore they are accepted at all times.

  - NMI
  - General illegal instructions
  - Trace
  - Trap instructions
  - CPU address error
  - DMA address error\*
- Independent vector addresses

All interrupt sources are assigned independent vector addresses, making it unnecessary for the source to be identified in the interrupt handling routine.
- 16 external interrupts

NMI is the highest-priority interrupt, and is accepted at all times. Rising edge or falling edge detection can be selected for NMI. Falling edge, rising edge, or both edge detection, or level sensing, can be selected for  $\overline{\text{IRQ14}}$  to  $\overline{\text{IRQ0}}$ .
- DMAC control

DMAC can be activated by means of interrupts.
- CPU priority control function

The priority levels can be assigned to the CPU and DMAC. The priority level of the CPU can be automatically assigned on an exception generation. Priority can be given to the CPU interrupt exception handling over that of the DMAC transfer.

Note: \* A DMA address error is generated within the DMAC.

A block diagram of the interrupt controller is shown in figure 5.1.

**Figure 5.1 Block Diagram of Interrupt Controller**

## 5.2 Input/Output Pins

Table 5.1 shows the pin configuration of the interrupt controller.

**Table 5.1 Pin Configuration**

Name	I/O	Function
NMI	Input	Nonmaskable External Interrupt Rising or falling edge can be selected.
IRQ14 to IRQ0	Input	Maskable External Interrupts Rising, falling, or both edges, or level sensing, can be selected.

## 5.3 Register Descriptions

The interrupt controller has the following registers.

- Interrupt control register (INTCR)
- CPU priority control register (CPUPCR)
- Interrupt priority registers A to G, I, K to O, Q, and R (IPRA to IPRG, IPRI, IPRK to IPRO, IPRQ, and IPRR)
- IRQ enable register (IER)
- IRQ sense control registers H and L (ISCRH, ISCRL)
- IRQ status register (ISR)
- Software standby release IRQ enable register (SSIER)

### 5.3.1 Interrupt Control Register (INTCR)

INTCR selects the interrupt control mode, and the detected edge for NMI.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	INTM1	INTM0	NMIEG	—	—	—
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved These are read-only bits and cannot be modified.
5	INTM1	0	R/W	Interrupt Control Select Mode 1 and 0
4	INTM0	0	R/W	These bits select either of two interrupt control modes for the interrupt controller. 00: Interrupt control mode 0 Interrupts are controlled by I bit in CCR. 01: Setting prohibited. 10: Interrupt control mode 2 Interrupts are controlled by bits I2 to I0 in EXR, and IPR. 11: Setting prohibited.

Bit	Bit Name	Initial Value	R/W	Description
3	NMIEG	0	R/W	NMI Edge Select Selects the input edge for the NMI pin. 0: Interrupt request generated at falling edge of NMI input 1: Interrupt request generated at rising edge of NMI input
2 to 0	—	All 0	R	Reserved These are read-only bits and cannot be modified.

### 5.3.2 CPU Priority Control Register (CPUPCR)

CPUPCR sets whether or not the CPU has priority over the DMAC. The interrupt exception handling by the CPU can be given priority over that of the DMAC transfer. The priority level of the DMAC for each channel is set by the DMAC control register.

Bit	7	6	5	4	3	2	1	0
Bit Name	CPUPCE	—	—	—	IPSETE	CPUP2	CPUP1	CPUP0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/(W)*	R/(W)*	R/(W)*

Note: \* When the IPSETE bit is set to 1, the CPU priority is automatically updated, so these bits cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	CPUPCE	0	R/W	CPU Priority Control Enable Controls the CPU priority control function. Setting this bit to 1 enables the CPU priority control over the DMAC. 0: CPU always has the lowest priority 1: CPU priority control enabled
6 to 4	—	All 0	R/W	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3	IPSETE	0	R/W	<p>Interrupt Priority Set Enable</p> <p>Controls the function which automatically assigns the interrupt priority level of the CPU. Setting this bit to 1 automatically sets bits CPUP2 to CPUP0 by the CPU interrupt mask bit (1 bit in CCR or bits I2 to I0 in EXR).</p> <p>0: Bits CPUP2 to CPUP0 are not updated automatically 1: The interrupt mask bit value is reflected in bits CPUP2 to CPUP0</p>
2	CPUP2	0	R/(W)*	CPU Priority Level 2 to 0
1	CPUP1	0	R/(W)*	<p>These bits set the CPU priority level. When the CPUPCE is set to 1, the CPU priority control function over the DMAC becomes valid and the priority of CPU processing is assigned in accordance with the settings of bits CPUP2 to CPUP0.</p> <p>000: Priority level 0 (lowest) 001: Priority level 1 010: Priority level 2 011: Priority level 3 100: Priority level 4 101: Priority level 5 110: Priority level 6 111: Priority level 7 (highest)</p>
0	CPUP0	0	R/(W)*	

Note: \* When the IPSETE bit is set to 1, the CPU priority is automatically updated, so these bits cannot be modified.

### 5.3.3 Interrupt Priority Registers A to G, I, K to O, Q, and R (IPRA to IPRG, IPRI, IPRK to IPRO, IPRQ, and IPRR)

IPR sets priority (levels 7 to 0) for interrupts other than NMI.

Setting a value in the range from B'000 to B'111 in the 3-bit groups of bits 14 to 12, 10 to 8, 6 to 4, and 2 to 0 assigns a priority level to the corresponding interrupt. For the correspondence between the interrupt sources and the IPR settings, see table 5.2.

Bit	15	14	13	12	11	10	9	8
Bit Name	—	IPR14	IPR13	IPR12	—	IPR10	IPR9	IPR8
Initial Value	0	1	1	1	0	1	1	1
R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W
Bit	7	6	5	4	3	2	1	0
Bit Name	—	IPR6	IPR5	IPR4	—	IPR2	IPR1	IPR0
Initial Value	0	1	1	1	0	1	1	1
R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This is a read-only bit and cannot be modified.
14	IPR14	1	R/W	Sets the priority level of the corresponding interrupt source.
13	IPR13	1	R/W	
12	IPR12	1	R/W	000: Priority level 0 (lowest) 001: Priority level 1 010: Priority level 2 011: Priority level 3 100: Priority level 4 101: Priority level 5 110: Priority level 6 111: Priority level 7 (highest)
11	—	0	R	Reserved This is a read-only bit and cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
10	IPR10	1	R/W	Sets the priority level of the corresponding interrupt source.
9	IPR9	1	R/W	
8	IPR8	1	R/W	000: Priority level 0 (lowest) 001: Priority level 1 010: Priority level 2 011: Priority level 3 100: Priority level 4 101: Priority level 5 110: Priority level 6 111: Priority level 7 (highest)
7	—	0	R	Reserved This is a read-only bit and cannot be modified.
6	IPR6	1	R/W	Sets the priority level of the corresponding interrupt source.
5	IPR5	1	R/W

### 5.3.4 IRQ Enable Register (IER)

IER enables or disables interrupt requests IRQ14 to IRQ0.

Bit	15	14	13	12	11	10	9	8
Bit Name	—	IRQ14E	IRQ13E	IRQ12E	IRQ11E	IRQ10E	IRQ9E	IRQ8E
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	7	6	5	4	3	2	1	0
Bit Name	IRQ7E	IRQ6E	IRQ5E	IRQ4E	IRQ3E	IRQ2E	IRQ1E	IRQ0E
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R/W	Reserved This bit is always read as 0. The write value should always be 0.
14	IRQ14E	0	R/W	IRQ14 Enable The IRQ14 interrupt request is enabled when this bit is 1.
13	IRQ13E	0	R/W	IRQ13 Enable The IRQ13 interrupt request is enabled when this bit is 1.
12	IRQ12E	0	R/W	IRQ12 Enable The IRQ12 interrupt request is enabled when this bit is 1.
11	IRQ11E	0	R/W	IRQ11 Enable The IRQ11 interrupt request is enabled when this bit is 1.
10	IRQ10E	0	R/W	IRQ10 Enable The IRQ10 interrupt request is enabled when this bit is 1.
9	IRQ9E	0	R/W	IRQ9 Enable The IRQ9 interrupt request is enabled when this bit is 1.

Bit	Bit Name	Initial Value	R/W	Description
8	IRQ8E	0	R/W	IRQ8 Enable The IRQ8 interrupt request is enabled when this bit is 1.
7	IRQ7E	0	R/W	IRQ7 Enable The IRQ7 interrupt request is enabled when this bit is 1.
6	IRQ6E	0	R/W	IRQ6 Enable The IRQ6 interrupt request is enabled when this bit is 1.
5	IRQ5E	0	R/W	IRQ5 Enable The IRQ5 interrupt request is enabled when this bit is 1.
4	IRQ4E	0	R/W	IRQ4 Enable The IRQ4 interrupt request is enabled when this bit is 1.
3	IRQ3E	0	R/W	IRQ3 Enable The IRQ3 interrupt request is enabled when this bit is 1.
2	IRQ2E	0	R/W	IRQ2 Enable The IRQ2 interrupt request is enabled when this bit is 1.
1	IRQ1E	0	R/W	IRQ1 Enable The IRQ1 interrupt request is enabled when this bit is 1.
0	IRQ0E	0	R/W	IRQ0 Enable The IRQ0 interrupt request is enabled when this bit is 1.

### 5.3.5 IRQ Sense Control Registers H and L (ISCRH and ISCR L)

ISCRH and ISCR L select the source that generates an interrupt request on pins  $\overline{\text{IRQ14}}$  to  $\overline{\text{IRQ0}}$ .

Upon changing the setting of ISCR,  $\text{IRQnF}$  ( $n = 14$  to  $0$ ) in ISR is often set to 1 accidentally through an internal operation. In this case, an interrupt exception handling is executed if an  $\text{IRQn}$  interrupt request is enabled. In order to prevent such an accidental interrupt from occurring, the setting of ISCR should be changed while the  $\text{IRQn}$  interrupt is disabled, and then the  $\text{IRQnF}$  in ISR should be cleared to 0.

### 5.3.6 IRQ Status Register (ISR)

ISR is an IRQ14 to IRQ0 interrupt request register.

Bit	15	14	13	12	11	10	9	8
Bit Name	—	IRQ14F	IRQ13F	IRQ12F	IRQ11F	IRQ10F	IRQ9F	IRQ8F
Initial Value	0	0	0	0	0	0	0	0
R/W	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*
Bit	7	6	5	4	3	2	1	0
Bit Name	IRQ7F	IRQ6F	IRQ5F	IRQ4F	IRQ3F	IRQ2F	IRQ1F	IRQ0F
Initial Value	0	0	0	0	0	0	0	0
R/W	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*

Note: \* Only 0 can be written, to clear the flag. The bit manipulation instructions or memory operation instructions should be used to clear the flag.

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R/(W)*	Reserved This bit is always read as 0. The write value should always be 0.
14	IRQ14F	0	R/(W)*	[Setting condition]
13	IRQ13F	0	R/(W)*	• When the interrupt selected by ISCR occurs
12	IRQ12F	0	R/(W)*	[Clearing conditions]
11	IRQ11F	0	R/(W)*	• Writing 0 after reading IRQnF = 1
10	IRQ10F	0	R/(W)*	• When interrupt exception handling is executed when low-level sensing is selected and $\overline{\text{IRQn}}$ input is high
9	IRQ9F	0	R/(W)*	
8	IRQ8F	0	R/(W)*	• When IRQn interrupt exception handling is executed when falling-, rising-, or both-edge sensing is selected
7	IRQ7F	0	R/(W)*	
6	IRQ6F	0	R/(W)*	
5	IRQ5F	0	R/(W)*	
4	IRQ4F	0	R/(W)*	
3	IRQ3F	0	R/(W)*	
2	IRQ2F	0	R/(W)*	
1	IRQ1F	0	R/(W)*	
0	IRQ0F	0	R/(W)*	

Note: \* Only 0 can be written, to clear the flag. The bit manipulation instructions or memory operation instructions should be used to clear the flag.

### 5.3.7 Software Standby Release IRQ Enable Register (SSIER)

SSIER selects pins used to leave software standby mode from pins  $\overline{\text{IRQ}}_{14}$  to  $\overline{\text{IRQ}}_0$ .

Bit	15	14	13	12	11	10	9	8
Bit Name	—	SSI14	SSI13	SSI12	SSI11	SSI10	SSI9	SSI8
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	7	6	5	4	3	2	1	0
Bit Name	SSI7	SSI6	SSI5	SSI4	SSI3	SSI2	SSI1	SSI0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R/W	Reserved This bit is always read as 0. The write value should always be 0.
14	SSI14	0	R/W	Software Standby Release IRQ Setting
13	SSI13	0	R/W	These bits select the $\overline{\text{IRQ}}_n$ pins used to leave software standby mode (n = 14 to 0).
12	SSI12	0	R/W	
11	SSI11	0	R/W	0: IRQ <sub>n</sub> requests are not sampled in software standby mode
10	SSI10	0	R/W	
9	SSI9	0	R/W	1: When an IRQ <sub>n</sub> request occurs in software standby mode, this LSI leaves software standby mode after the oscillation settling time has elapsed
8	SSI8	0	R/W	
7	SSI7	0	R/W	
6	SSI6	0	R/W	
5	SSI5	0	R/W	
4	SSI4	0	R/W	
3	SSI3	0	R/W	
2	SSI2	0	R/W	
1	SSI1	0	R/W	
0	SSI0	0	R/W	

## 5.4 Interrupt Sources

### 5.4.1 External Interrupts

There are sixteen external interrupts: NMI and IRQ14 to IRQ0. These interrupts can be used to leave software standby mode.

#### (1) NMI Interrupts:

Nonmaskable interrupt request (NMI) is the highest-priority interrupt, and is always accepted by the CPU regardless of the interrupt control mode or the settings of the CPU interrupt mask bits. The NMIEG bit in INTCR selects whether an interrupt is requested at the rising or falling edge on the NMI pin.

When an NMI interrupt is generated, the interrupt controller determines that an error has occurred, and performs the following procedure.

- Sets the ERRF bit in DMDR\_0 to 1.
- Clears the DTE bits for all the channels of the DMAC and forcibly halts transfer.

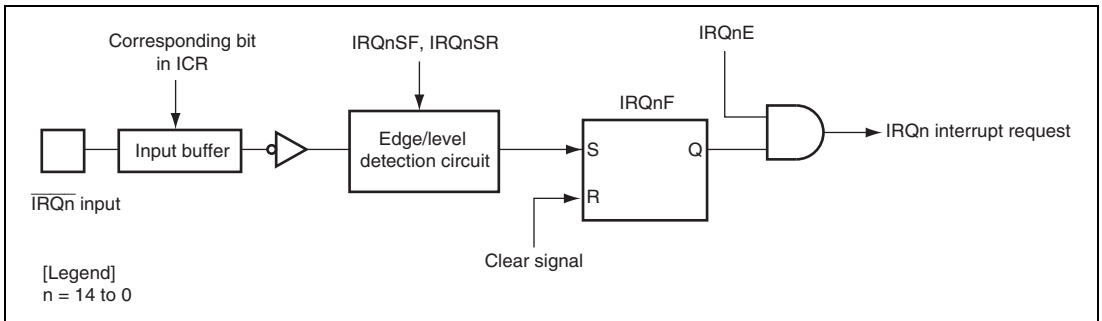

#### (2) IRQn Interrupts:

An IRQn interrupt is requested by a signal input on pins  $\overline{\text{IRQ14}}$  to  $\overline{\text{IRQ0}}$ .  $\overline{\text{IRQn}}$  (n = 14 to 0) have the following features:

- Using ISCR, it is possible to select whether an interrupt is generated by a low level, falling edge, rising edge, or both edges, on pins  $\overline{\text{IRQn}}$ .
- Enabling or disabling of interrupt requests IRQn can be selected by IER.
- The interrupt priority can be set by IPR.
- The status of interrupt requests IRQn is indicated in ISR. ISR flags can be cleared to 0 by software. The bit manipulation instructions or memory operation instructions should be used to clear the flag in ISR.

Detection of IRQn interrupts is enabled through the P1ICR, P2ICR, P5ICR, and P6ICR register settings, and does not change regardless of the output setting. However, when a pin is used as an external interrupt input pin, the pin must not be used as an I/O pin for another function by clearing the corresponding DDR bit to 0.

A block diagram of interrupts IRQn is shown in figure 5.2.

**Figure 5.2 Block Diagram of Interrupts  $IRQ_n$**

When the IRQ sensing control in ISCR is set to a low level of signal  $\overline{IRQ_n}$ , the level of  $\overline{IRQ_n}$  should be held low until an interrupt handling starts. Then set the corresponding input signal  $\overline{IRQ_n}$  to high in the interrupt handling routine and clear the  $IRQ_nF$  to 0. Interrupts may not be executed when the corresponding input signal  $\overline{IRQ_n}$  is set to high before the interrupt handling begins.

#### 5.4.2 Internal Interrupts

The sources for internal interrupts from on-chip peripheral modules have the following features:

- For each on-chip peripheral module there are flags that indicate the interrupt request status, and enable bits that enable or disable these interrupts. They can be controlled independently. When the enable bit is set to 1, an interrupt request is issued to the interrupt controller.
- The interrupt priority can be set by means of IPR.
- The DMAC can be activated by a TPU, SCI, RCAN-ET, SSU, or other interrupt request.
- DMAC activation can be controlled by the CPU priority control function over the DMAC.

## 5.6 Interrupt Control Modes and Interrupt Operation

The interrupt controller has two interrupt control modes: interrupt control mode 0 and interrupt control mode 2. Interrupt operations differ depending on the interrupt control mode. The interrupt control mode is selected by INTCR. Table 5.3 shows the differences between interrupt control mode 0 and interrupt control mode 2.

**Table 5.3 Interrupt Control Modes**

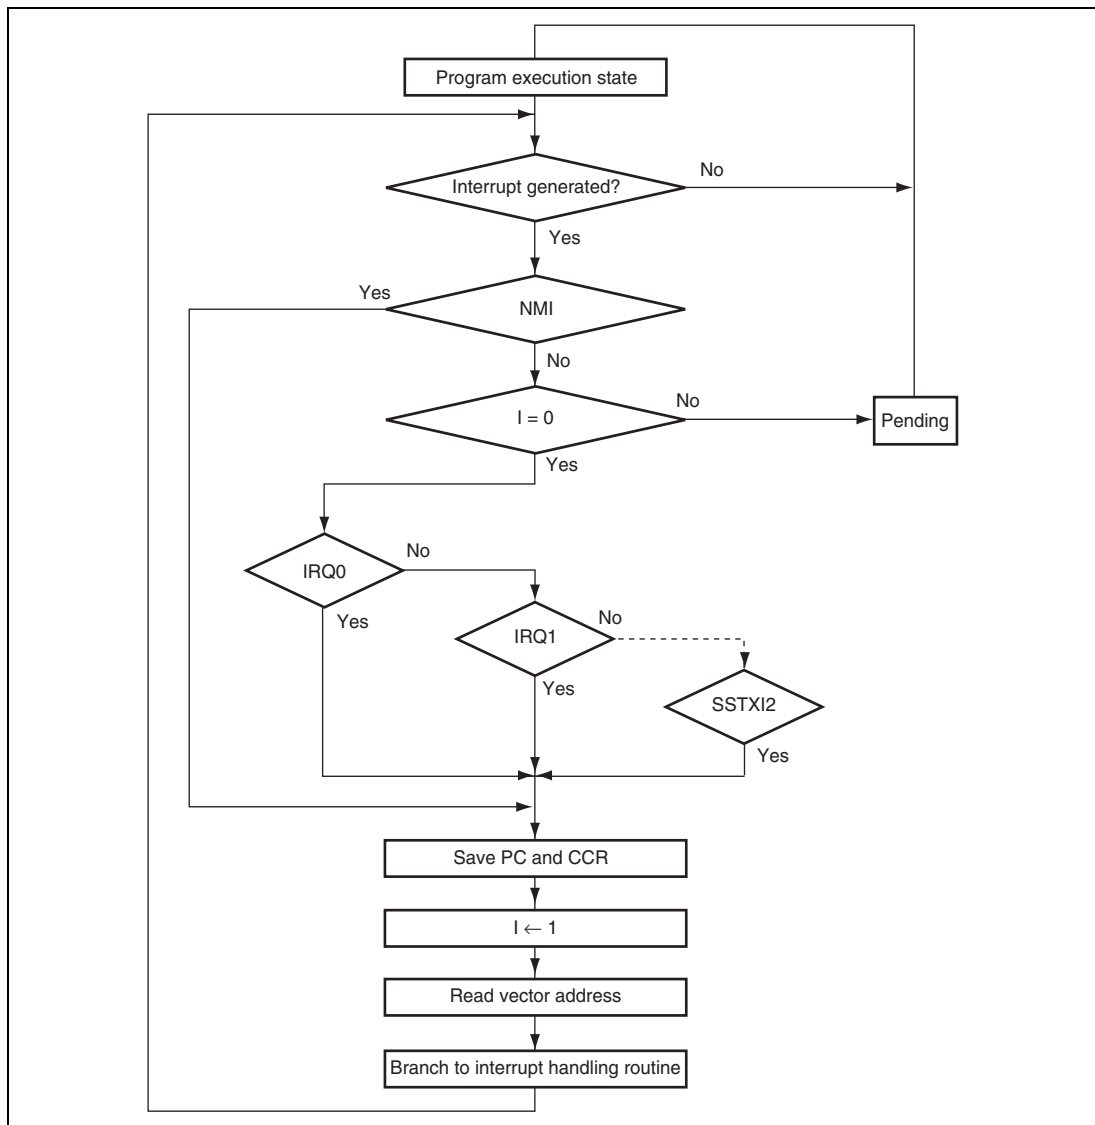

Interrupt Control Mode	Priority Setting Register	Interrupt Mask Bit	Description
0	Default	I	The priority levels of the interrupt sources are fixed default settings. The interrupts except for NMI is masked by the I bit.
2	IPR	I2 to I0	Eight priority levels can be set for interrupt sources except for NMI with IPR. 8-level interrupt mask control is performed by bits I2 to I0.

### 5.6.1 Interrupt Control Mode 0

In interrupt control mode 0, interrupt requests except for NMI are masked by the I bit in CCR of the CPU. Figure 5.3 shows a flowchart of the interrupt acceptance operation in this case.

1. If an interrupt request occurs when the corresponding interrupt enable bit is set to 1, the interrupt request is sent to the interrupt controller.
2. If the I bit in CCR is set to 1, only an NMI interrupt is accepted, and other interrupt requests are held pending. If the I bit is cleared to 0, an interrupt request is accepted.
3. For multiple interrupt requests, the interrupt controller selects the interrupt request with the highest priority, sends the request to the CPU, and holds other interrupt requests pending.
4. When the CPU accepts the interrupt request, it starts interrupt exception handling after execution of the current instruction has been completed.
5. The PC and CCR contents are saved to the stack area during the interrupt exception handling. The PC contents saved on the stack is the address of the first instruction to be executed after returning from the interrupt handling routine.
6. Next, the I bit in CCR is set to 1. This masks all interrupts except NMI.

7. The CPU generates a vector address for the accepted interrupt and starts execution of the interrupt handling routine at the address indicated by the contents of the vector address in the vector table.

**Figure 5.3 Flowchart of Procedure Up to Interrupt Acceptance in Interrupt Control Mode 0**

### 5.6.2 Interrupt Control Mode 2

In interrupt control mode 2, interrupt requests except for NMI are masked by comparing the interrupt mask level (I2 to I0 bits) in EXR of the CPU and the IPR setting. There are eight levels in mask control. Figure 5.4 shows a flowchart of the interrupt acceptance operation in this case.

1. If an interrupt request occurs when the corresponding interrupt enable bit is set to 1, an interrupt request is sent to the interrupt controller.
2. For multiple interrupt requests, the interrupt controller selects the interrupt request with the highest priority according to the IPR setting, and holds other interrupt requests pending. If multiple interrupt requests has the same priority, an interrupt request is selected according to the default setting shown in table 5.2.
3. Next, the priority of the selected interrupt request is compared with the interrupt mask level set in EXR. When the interrupt request does not have priority over the mask level set, it is held pending, and only an interrupt request with a priority over the interrupt mask level is accepted.
4. When the CPU accepts an interrupt request, it starts interrupt exception handling after execution of the current instruction has been completed.
5. The PC, CCR, and EXR contents are saved to the stack area during interrupt exception handling. The PC saved on the stack is the address of the first instruction to be executed after returning from the interrupt handling routine.
6. The T bit in EXR is cleared to 0. The interrupt mask level is rewritten with the priority of the accepted interrupt. If the accepted interrupt is NMI, the interrupt mask level is set to H'7.
7. The CPU generates a vector address for the accepted interrupt and starts execution of the interrupt handling routine at the address indicated by the contents of the vector address in the vector table.

**Figure 5.4 Flowchart of Procedure Up to Interrupt Acceptance in Interrupt Control Mode 2**

### 5.6.3 Interrupt Exception Handling Sequence

Figure 5.5 shows the interrupt exception handling sequence. The example is for the case where interrupt control mode 0 is set in maximum mode, and the program area and stack area are in on-chip memory.

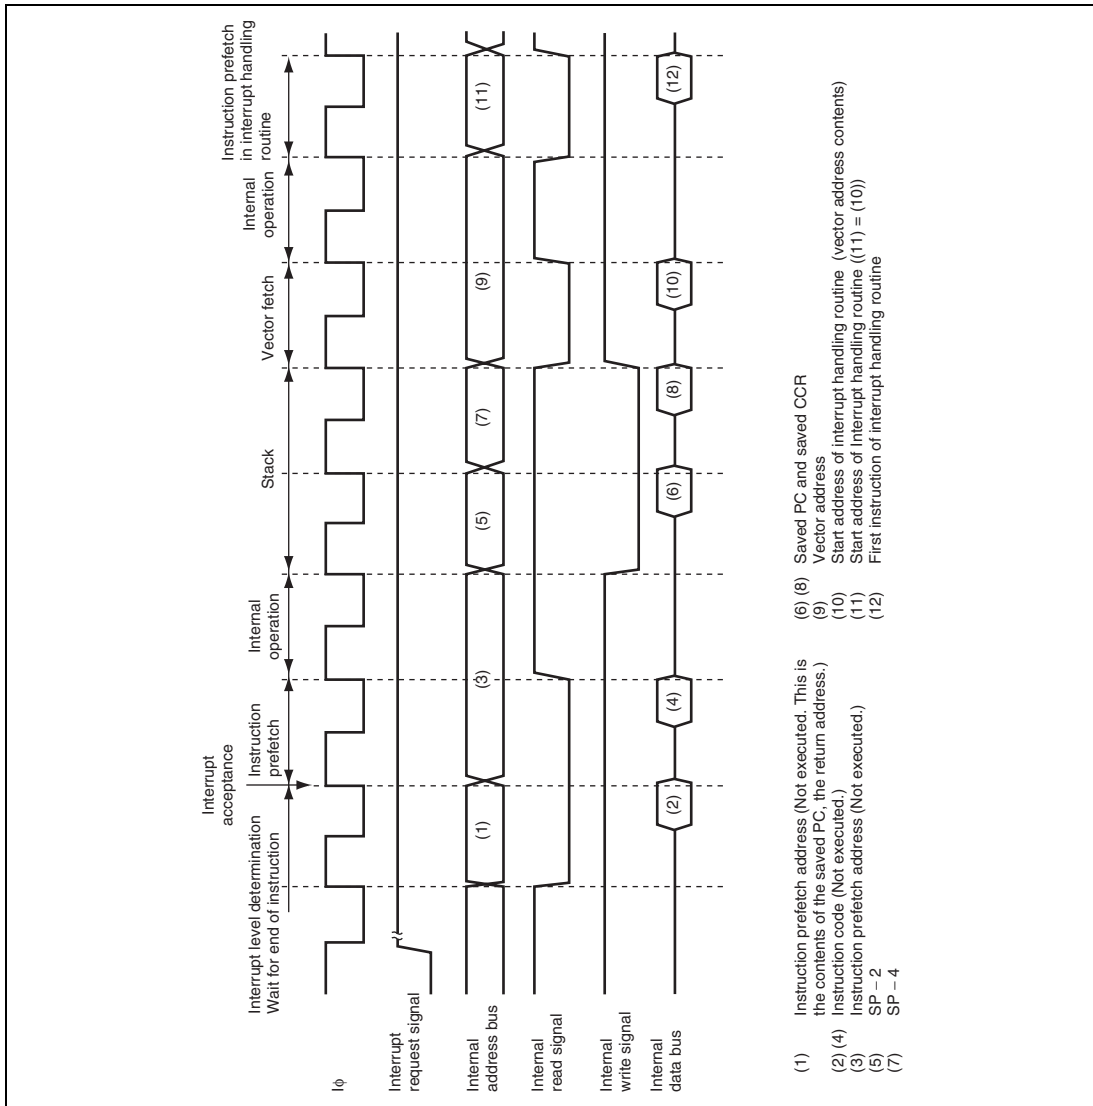

Figure 5.5 Interrupt Exception Handling

## 5.6.4 Interrupt Response Times

Table 5.4 shows interrupt response times – the interval between generation of an interrupt request and execution of the first instruction in the interrupt handling routine. The symbols for execution states used in table 5.4 are explained in table 5.5.

This LSI is capable of fast word transfer to on-chip memory, so allocating the program area in on-chip ROM and the stack area in on-chip RAM enables high-speed processing.

**Table 5.4 Interrupt Response Times**

Execution State	Normal Mode* <sup>5</sup>		Advanced Mode		Maximum Mode <sup>5</sup>	
	Interrupt Control Mode 0	Interrupt Control Mode 2	Interrupt Control Mode 0	Interrupt Control Mode 2	Interrupt Control Mode 0	Interrupt Control Mode 2
	Interrupt priority decision* <sup>1</sup>			3		
Number of states until executing instruction ends* <sup>2</sup>			1 to 19 + 2·S <sub>i</sub>			
PC, CCR, EXR stacking	S <sub>k</sub> to 2·S <sub>k</sub> * <sup>6</sup>	2·S <sub>k</sub>	S <sub>k</sub> to 2·S <sub>k</sub> * <sup>6</sup>	2·S <sub>k</sub>	2·S <sub>k</sub>	2·S <sub>k</sub>
Vector fetch			S <sub>h</sub>			
Instruction fetch* <sup>3</sup>			2·S <sub>i</sub>			
Internal processing* <sup>4</sup>			2			
Total (using on-chip memory)	10 to 31	11 to 31	10 to 31	11 to 31	11 to 31	11 to 31

- Notes:
- Two states for an internal interrupt.
  - In the case of the MULXS or DIVXS instruction
  - Prefetch after interrupt acceptance or for an instruction in the interrupt handling routine.
  - Internal operation after interrupt acceptance or after vector fetch
  - Not available in this LSI.
  - When setting the SP value to 4n, the interrupt response time is S<sub>k</sub>; when setting to 4n + 2, the interrupt response time is 2·S<sub>k</sub>.

**Table 5.5 Number of Execution States in Interrupt Handling Routine**

Symbol	On-Chip Memory	Object of Access					
		External Device					
		8-Bit Bus		16-Bit Bus		32-Bit Bus	
	2-State Access	3-State Access	2-State Access	3-State Access	2-State Access	3-State Access	
Vector fetch $S_h$	1	8	12 + 4m	4	6 + 2m	2	3 + m
Instruction fetch $S_i$	1	4	6 + 2m	2	3 + m	2	3 + m
Stack manipulation $S_x$	2	8	12 + 4m	4	6 + 2m	2	3 + m

[Legend]

m: Number of wait cycles in an external device access.

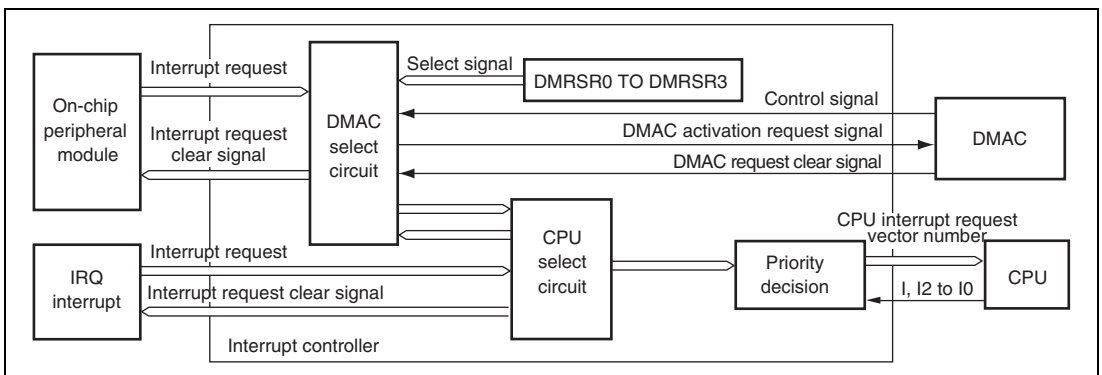

### 5.6.5 DMAC Activation by Interrupt

The DMAC can be activated by an interrupt. In this case, the following options are available:

- Interrupt request to the CPU
- Activation request to the DMAC
- Combination of the above

For details on interrupt requests that can be used to activate the DMAC, see table 5.2 and section 7, DMA Controller (DMAC).

Figure 5.6 shows a block diagram of the DMAC and interrupt controller.

**Figure 5.6 Block Diagram of DMAC and Interrupt Controller**

## (1) Selection of Interrupt Sources:

A DMAC activation request source for each channel is selected by DMRSR. The selected request is passed to the DMAC via a selector. When transfer by an on-chip module interrupt is enabled (DTF1 = 1, DTF0 = 0, and DTE = 1 in DMDR) and the DTA bit in DMDR is set to 1, the interrupt source selected for the DMAC activation source is controlled by the DMAC and cannot be used as a CPU interrupt source.

Interrupt sources that are not controlled by the DMAC are set for CPU interrupt sources.

When the same interrupt source is set as both the DMAC activation source and CPU interrupt source, the DMAC must be given priority over the CPU. If the IPSETE bit in CPUPCR is set to 1, the priority is determined according to the IPR setting. Therefore, the CPUP setting or the IPR setting corresponding to the interrupt source must be set to lower than or equal to the DMAP setting. If the CPU is given priority, the DMAC may not be activated, and the data transfer may not be performed.

## (2) Operation Order

If the same interrupt is selected as both the DMAC activation source and CPU interrupt source, the respective operations are performed independently.

Table 5.6 lists the selection of interrupt sources and interrupt source clear control by means of the setting of the DTA bit in DMDR of the DMAC.

**Table 5.6 Interrupt Source Selection and Clear Control**

Setting		
DMAC	Interrupt Source Selection/Clear Control	
DTA	DMAC	CPU
0	O	√
1	√	X

[Legend]

√: The corresponding interrupt is used. The interrupt source is cleared.

(The interrupt source flag must be cleared in the CPU interrupt handling routine.)

O: The corresponding interrupt is used. The interrupt source is not cleared.

X: The corresponding interrupt is not available.

### (3) Usage Note

The interrupt sources of the SCI, A/D converter, RCAN-ET and SSU are cleared according to the setting shown in table 5.6, when the DMAC reads/writes the prescribed register.

## 5.7 CPU Priority Control Function Over DMAC

The interrupt controller has a function to control the priority among the DMAC and the CPU by assigning priority levels to the DMAC and CPU. Since the priority level can automatically be assigned to the CPU on an interrupt occurrence, it is possible to execute the CPU interrupt exception handling prior to the DMAC transfer.

The priority level of the CPU is assigned by bits CPUP2 to CPUP0 in CPUPCR. The priority level of the DMAC is assigned to each channel by bits DMAP2 to DMAP0 in the DMA mode control registers 0 to 3 (DMDR\_0 to DMDR\_3).

The priority control function over the DMAC is enabled by setting the CPUPCE bit in CPUPCR to 1. When the CPUPCE bit is 1, the DMAC activation source is controlled according to the respective priority level.

The priority level of the DMAC can be specified for each channel. The DMAC activation source is controlled according to the priority level of the CPU and the priority level of the DMAC indicated by bits DMAP2 to DMAP0. If the CPU has priority, the DMAC activation source is held. The DMAC is activated when the condition by which the activation source is held is cancelled (CPUPCE = 1 and value of bits CPUP2 to CPUP0 is greater than that of bits DMAP2 to DMAP0). When the different priority levels of the DMAC are assigned for the channels, the channel having higher priority continues to transfer while the channel having lower priority than the CPU is held.

There are two methods for assigning the priority level to the CPU by the IPSETE bit in CPUPCR. Setting the IPSETE bit to 1 enables a function to automatically assign the value of the interrupt mask bit of the CPU to the CPU priority level. Clearing the IPSETE bit to 0 disables the function to automatically assign the priority level. Therefore, the priority level is assigned directly by software rewriting bits CPUP2 to CPUP0. Even if the IPSETE bit is 1, the priority level of the CPU is software assignable by rewriting the interrupt mask bit of the CPU (I bit in CCR or I2 to I0 bits in EXR).

The priority level which is automatically assigned when the IPSETE bit is 1 differs according to the interrupt control mode.

In interrupt control mode 0, the I bit in CCR of the CPU is reflected in bit CPUP2. Bits CPUP1 and CPUP0 are fixed 0. In interrupt control mode 2, the values of bits I2 to I0 in EXR of the CPU are reflected in bits CPUP2 to CPUP0.

Table 5.7 shows the CPU priority control.

**Table 5.7 CPU Priority Control**

Interrupt Control Mode	Interrupt Priority	Interrupt Mask Bit	IPSETE in CPUPCR	Control Status	
				CPUP2 to CPUP0	Updating of CPUP2 to CPUP0
0	Default	I = any	0	B'111 to B'000	Enabled
		I = 0	1	B'000	Disabled
		I = 1		B'100	
2	IPR setting	I2 to I0	0	B'111 to B'000	Enabled
			1	I2 to I0	Disabled

Table 5.8 shows an setting example of the priority control function over the DMAC and the transfer request control state. Although the DMAC priority levels can be assigned for each channel, table 5.8 gives a single channel description. Thus, transfer for each channel can be performed independently by assigning the different priority levels.

**Table 5.8 Example of Priority Control Function Setting and Control State**

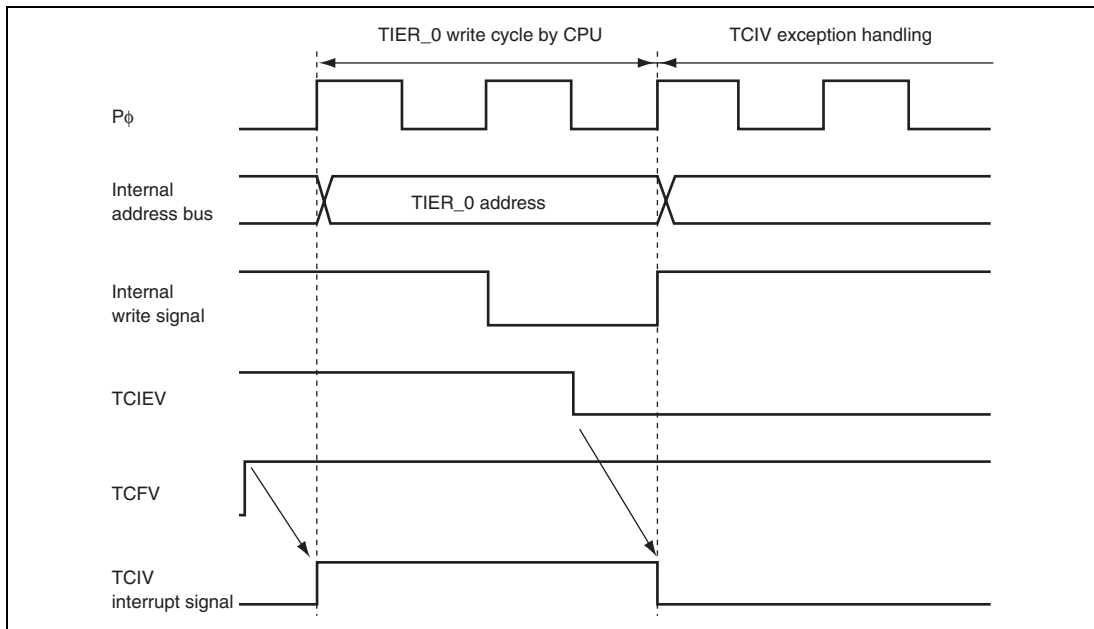

Interrupt Control Mode	CPUPCE in CPUPCR	CPUP2 to CPUP0	DMAP2 to DMAP0	Transfer Request Control State
				DMAC
0	0	Any	Any	Enabled
	1	B'000	B'000	Enabled
		B'100	B'000	Masked
		B'100	B'011	Masked
		B'100	B'101	Enabled
		B'000	B'101	Enabled
2	0	Any	Any	Enabled
	1	B'000	B'000	Enabled
		B'000	B'101	Enabled
		B'011	B'101	Enabled
		B'100	B'101	Enabled
		B'101	B'101	Enabled
		B'110	B'101	Masked
		B'111	B'101	Masked
		B'101	B'101	Enabled
		B'101	B'101	Enabled

## 5.8 Usage Notes

### 5.8.1 Conflict between Interrupt Generation and Disabling

When an interrupt enable bit is cleared to 0 to mask the interrupt, the masking becomes effective after execution of the instruction.

When an interrupt enable bit is cleared to 0 by an instruction such as BCLR or MOV, if an interrupt is generated during execution of the instruction, the interrupt concerned will still be enabled on completion of the instruction, and so interrupt exception handling for that interrupt will be executed on completion of the instruction. However, if there is an interrupt request with priority over that interrupt, interrupt exception handling will be executed for the interrupt with priority, and another interrupt will be ignored. The same also applies when an interrupt source flag is cleared to 0. Figure 5.7 shows an example in which the TCIEV bit in TIER of the TPU is cleared to 0. The above conflict will not occur if an enable bit or interrupt source flag is cleared to 0 while the interrupt is masked.

**Figure 5.7 Conflict between Interrupt Generation and Disabling**

### 5.8.2 Instructions that Disable Interrupts

Instructions that disable interrupts immediately after execution are LDC, ANDC, ORC, and XORC. After any of these instructions is executed, all interrupts including NMI are disabled and the next instruction is always executed. When the I bit is set by one of these instructions, the new value becomes valid two states after execution of the instruction ends.

### 5.8.3 Times when Interrupts are Disabled

There are times when interrupt acceptance is disabled by the interrupt controller.

The interrupt controller disables interrupt acceptance for a 3-state period after the CPU has updated the mask level with an LDC, ANDC, ORC, or XORC instruction, and for a period of writing to the registers of the interrupt controller.

### 5.8.4 Interrupts during Execution of EEPMOV Instruction

Interrupt operation differs between the EEPMOV.B and the EEPMOV.W instructions.

With the EEPMOV.B instruction, an interrupt request (including NMI) issued during the transfer is not accepted until the transfer is completed.

With the EEPMOV.W instruction, if an interrupt request is issued during the transfer, interrupt exception handling starts at the end of the individual transfer cycle. The PC value saved on the stack in this case is the address of the next instruction. Therefore, if an interrupt is generated during execution of an EEPMOV.W instruction, the following coding should be used.

```
L1:    EEPMOV.W  
      MOV.W  R4, R4  
      BNE   L1
```

### 5.8.5 Interrupts during Execution of MOVMD and MOVSD Instructions

With the MOVMD and MOVSD instructions, if an interrupt request is issued during the transfer, interrupt exception handling starts at the end of the individual transfer cycle. The PC value saved on the stack in this case is the address of the MOVMD or MOVSD instruction. The transfer of the remaining data is resumed after returning from the interrupt handling routine.

### 5.8.6 Interrupt Flags of Peripheral Modules

To clear an interrupt request flag of a peripheral module by the CPU, the flag must be read from after being cleared within the interrupt handling routine even if the peripheral module clock is not generated by dividing the system clock. This makes the request signal synchronized with the system clock.

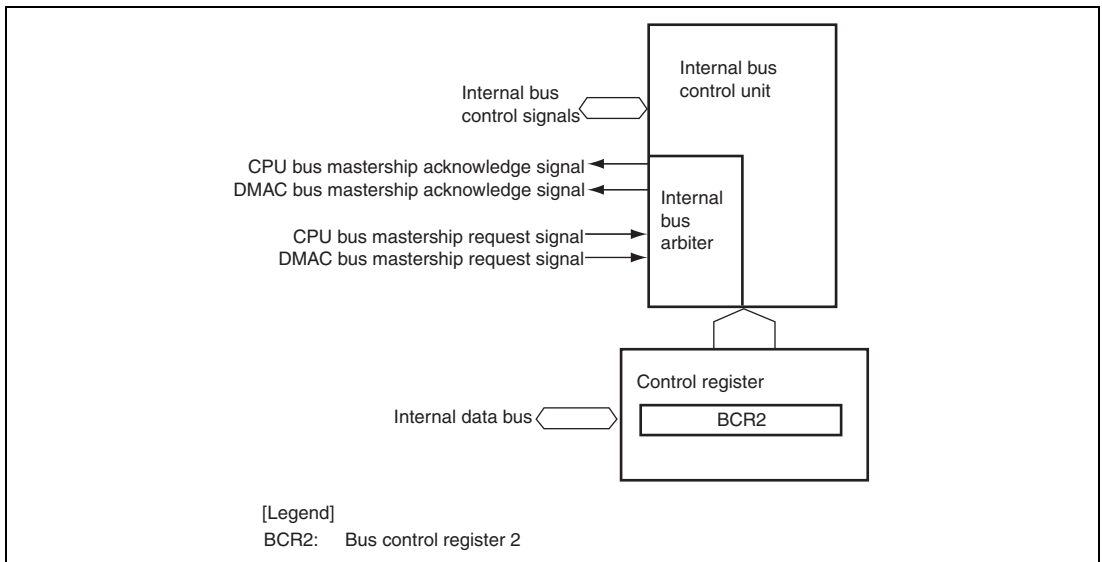

## Section 6 Bus Controller (BSC)

This LSI has an on-chip bus controller (BSC) that has a bus arbitration function and controls the operation of the internal bus masters; CPU and DMAC.

### 6.1 Features

- Write data buffer function  
Write access to an on-chip peripheral module and access to the on-chip memory can be performed in parallel.
- Bus arbitration function  
Includes a bus arbiter that arbitrates bus mastership between the CPU and DMAC. Bus mastership can be shared between the CPU and DMAC when a conflict occurs.
- Multi-clock function  
On-chip peripheral functions can be synchronized with the on-chip peripheral module clock (P $\phi$ ).

A block diagram of the bus controller is shown in figure 6.1.

**Figure 6.1 Block Diagram of Bus Controller**

## 6.2 Register Descriptions

The bus controller has the following registers.

- Bus control register 2 (BCR2)

### 6.2.1 Bus Control Register 2 (BCR2)

BCR2 is used for bus arbitration control of the CPU and DMAC, and enabling/disabling of the write data buffer function to the peripheral device.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	—	IBCCS	—	—	—	PWDBE
Initial Value	0	0	0	0	0	0	1	0
R/W	R	R	R/W	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved These are read-only bits and cannot be modified.
5	—	0	R/W	Reserved This bit is always read as 0. The write value should always be 0.
4	IBCCS	0	R/W	Internal Bus Cycle Control Select Selects the internal bus arbiter function. 0: Releases the bus mastership according to the priority 1: Executes the bus cycles alternatively when a CPU bus mastership request conflicts with a DMAC bus mastership request
3, 2	—	All 0	R	Reserved These are read-only bits and cannot be modified.
1	—	1	R/W	Reserved This bit is always read as 1. The write value should always be 1.
0	PWDBE	0	R/W	Peripheral Module Write Data Buffer Enable Specifies whether or not to use the write data buffer function for the peripheral module write cycles. 0: Write data buffer function not used 1: Write data buffer function used

### 6.3 Bus Configuration

Figure 6.2 shows the internal bus configuration of this LSI. The internal bus of this LSI consists of the following two types.

- **Internal system bus 1**  
A bus that connects the CPU, DMAC, on-chip ROM, on-chip RAM, and internal peripheral bus.
- **Internal peripheral bus**  
A bus that accesses registers in the DMAC, bus controller and interrupt controller and registers of peripheral modules such as SCI and timer.

**Figure 6.2 Internal Bus Configuration**

## 6.4 Multi-Clock Function

The internal functions of this LSI operate synchronously with the system clock ( $I\phi$ ) or the peripheral module clock ( $P\phi$ ). Table 6.1 shows the synchronization clock and their corresponding functions.

**Table 6.1 Synchronization Clocks and Their Corresponding Functions**

Synchronization Clock	Function Name
$I\phi$	MCU operating mode Interrupt controller Bus controller CPU DMAC Internal memory Clock pulse generator Power down control
$P\phi$	I/O ports TPU PPG WDT SCI RCAN-ET SSU A/D

The frequency of each synchronization clock ( $I\phi$  and  $P\phi$ ) is specified by the system clock control register (SCKCR) independently. For further details, see section 18, Clock Pulse Generator.

## 6.5 Internal Bus

### 6.5.1 Access to Internal Address Space

The internal address spaces of this LSI are the on-chip ROM space, on-chip RAM space and register space for the on-chip peripheral modules. The number of cycles necessary for access differs according to the space.

Table 6.2 shows the number of access cycles for each on-chip memory space.

**Table 6.2 Number of Access Cycles for On-Chip Memory Spaces**

Access Space	Access	Number of Access Cycles
On-chip ROM space	Read	One $1\phi$ cycle
On-chip RAM space	Read	One $1\phi$ cycle
	Write	Two $1\phi$ cycles

In access to the registers for on-chip peripheral modules, the number of access cycles differs according to the register to be accessed. When the dividing ratio of the operating clock of a bus master and that of a peripheral module is 1 : n, synchronization cycles using a clock divided by 0 to n-1 are inserted for register access.

**Table 6.3 Number of Access Cycles for Registers of On-Chip Peripheral Modules**

Module to be Accessed	Number of Cycles		Write Data Buffer Function
	Read	Write	
DMAC registers		$21\phi$	Disabled
MCU operating mode, clock pulse generator, power-down control, interrupt controller, and bus controller registers	$21\phi$	$31\phi$	Disabled
I/O port PFCR registers and WDT registers	$2P\phi$	$3P\phi$	Disabled
TPU, PPG, SCI, and A/D registers and I/O port registers other than PFCR		$2P\phi$	Enabled
RCAN-ET registers		$4P\phi$	Enabled
SSU registers		$3P\phi$	Enabled

## 6.6 Write Data Buffer Function

### 6.6.1 Write Data Buffer Function for Peripheral Module

This LSI has a write data buffer function for the peripheral module. Using the write data buffer function enables external writes and on-chip memory accesses in parallel. The write data buffer function is made available by setting the PWDBE bit in BCR2 to 1.

Figure 6.3 shows an example of the timing when the write data buffer function is used. When this function is used, if a peripheral module write continues for two cycles or longer, and there is an internal access next, only the peripheral module write is executed in the first two cycles. However, from the next cycle onward, on-chip memory accesses are executed in parallel, without waiting for the peripheral module write to be complete.

**Figure 6.3 Example of Timing when Write Data Buffer Function is Used**

## 6.7 Bus Arbitration

This LSI has bus arbiters that arbitrate bus mastership operations (bus arbitration). The internal bus arbiter handles the CPU and DMAC accesses.

The bus arbiters decide priority at the prescribed timing, and permit use of the bus by means of the bus request acknowledge signal.

### 6.7.1 Operation

The bus arbiter detects the bus masters' bus request signals, and if the bus is requested, sends a bus request acknowledge signal to the bus master. If there are bus requests from more than one bus master, the bus request acknowledge signal is sent to the one with the highest priority. When a bus master receives the bus request acknowledge signal, it takes possession of the bus until that signal is canceled.

The priority of the internal bus arbitration:

(High) DMAC > CPU (Low)

If the DMAC accesses continue, the CPU can be given priority over the DMAC to execute the bus cycles alternatively between them by setting the IBCCS bit in BCR2.

### 6.7.2 Bus Transfer Timing

Even if a bus request is received from a bus master with a higher priority over that of the bus master that has taken control of the bus and is currently operating, the bus is not necessarily transferred immediately. There are specific timings at which each bus master can release the bus.

#### (1) CPU

The CPU is the lowest-priority bus master, and if a bus request is received from the DMAC, the bus arbiter transfers the bus to the bus master that issued the request.

The timing for transfer of the bus is at the end of the bus cycle. In sleep mode, the bus is transferred synchronously with the clock.

Note, however, that the bus cannot be transferred in the following cases.

- The word or longword access is performed in some divisions.
- Stack handling is performed in multiple bus cycles.

- Transfer data read or write by memory transfer instructions, block transfer instructions, or TAS instruction.

(In the block transfer instructions, the bus can be transferred in the write cycle and the following transfer data read cycle.)

- From the target read to write in the bit manipulation instructions or memory operation instructions.

(In an instruction that performs no write operation according to the instruction condition, up to a cycle corresponding the write cycle)

## (2) DMAC

The DMAC sends the internal bus arbiter a request for the bus when an activation request is generated.

Once the DMAC takes control of the bus, it continues the transfer processing cycles, or releases the bus every transfer cycle.

The bus cannot be transferred in the following cases.

- Between a read cycle and the corresponding write cycle in dual address mode

While the IBCCS bit in BCR2 is cleared to 0, the bus cannot be transferred in the following cases.

- During 1-block data transfer in block transfer mode
- During burst access transfer

The DMAC releases the bus when the consecutive transfer cycles completed except the above cycles.

## 6.8 Bus Controller Operation in Reset

In a reset, this LSI, including the bus controller, enters the reset state immediately, and any executing bus cycle is aborted.

## 6.9 Usage Notes

**All-Module-Clock-Stop Mode:** In this LSI, if the ACSE bit in MSTPCR is set to 1 with the setting for all peripheral module clocks to be stopped (MSTPCR = H'FFFFFFF), a transition is made to the all-module-clock-stop mode. For details, see section 19, Power-Down Modes.

## Section 7 DMA Controller (DMAC)

This LSI includes a 4-channel DMA controller (DMAC).

### 7.1 Features

- Maximum of 4-G byte address space can be accessed
- Byte, word, or longword can be set as data transfer unit
- Maximum of 4-G bytes (4,294,967,295 bytes) can be set as total transfer size  
Supports free-running mode in which total transfer size setting is not needed
- DMAC activation methods are auto-request, on-chip module interrupt, and external request.  
Auto request: CPU activates (cycle stealing or burst access can be selected)  
On-chip module interrupt: Interrupt requests from on-chip peripheral modules can be selected as an activation source  
External request\*: Low level or falling edge detection of the  $\overline{\text{DREQ}}$  signal can be selected (external request is available for all four channels)
- Dual or single address mode can be selected as address mode  
Dual address mode: Both source and destination are specified by addresses  
Single address mode\*: Either source or destination is specified by the  $\overline{\text{DREQ}}$  signal and the other is specified by address
- Normal, repeat, or block transfer can be selected as transfer mode  
Normal transfer mode: One byte, one word, or one longword data is transferred at a single transfer request  
Repeat transfer mode: One byte, one word, or one longword data is transferred at a single transfer request  
Repeat size of data is transferred and then a transfer address returns to the transfer start address  
Up to 65536 transfers (65,536 bytes/words/longwords) can be set as repeat size  
Block transfer mode: One block data is transferred at a single transfer request  
Up to 65,536 bytes/words/longwords can be set as block size
- Extended repeat area function which repeats the addressees within a specified area using the transfer address with the fixed upper bits (ring buffer transfer can be performed, as an example) is available  
One bit (two bytes) to 27 bits (128 Mbytes) for transfer source and destination can be set as extended repeat areas

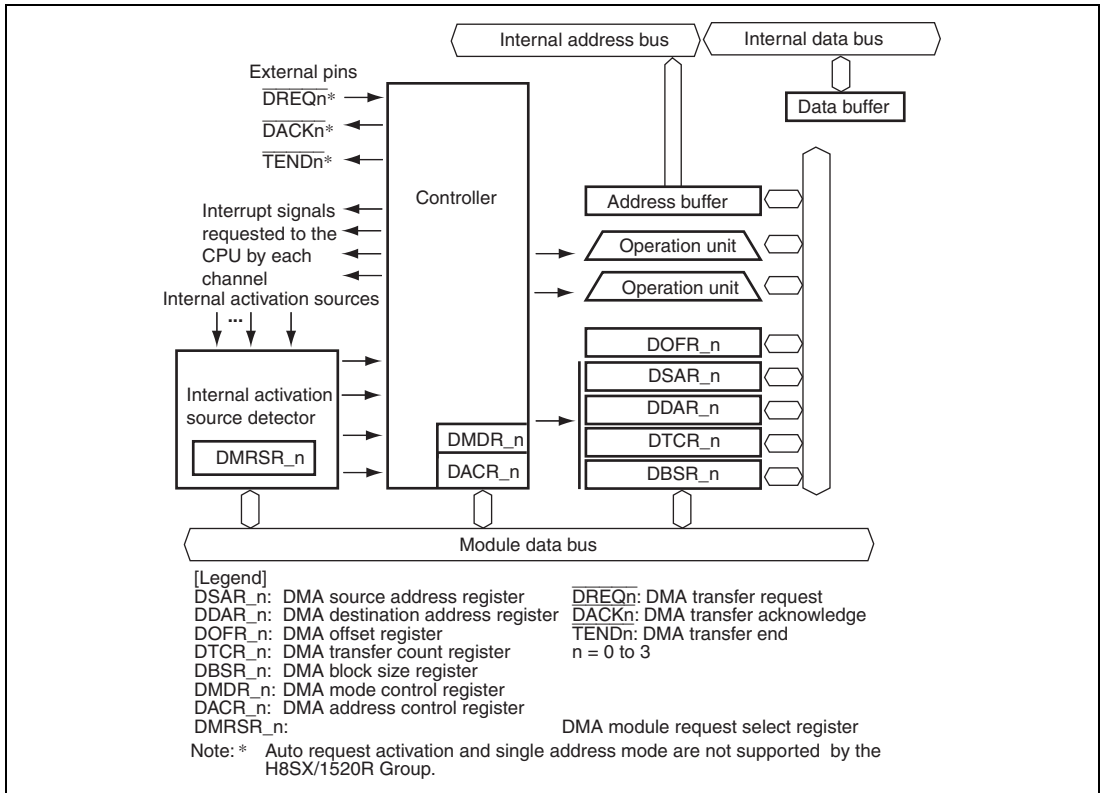

- Address update can be selected from fixed address, offset addition, and increment or decrement by 1, 2, or 4  
Address update by offset addition enables to transfer data at addresses which are not placed continuously
- Word or longword data can be transferred to an address which is not aligned with the respective boundary  
Data is divided according to its address (byte or word) when it is transferred
- Two types of interrupts can be requested to the CPU  
A transfer end interrupt is generated after the number of data specified by the transfer counter is transferred. A transfer escape end interrupt is generated when the remaining total transfer size is less than the transfer data size at a single transfer request, when the repeat size of data transfer is completed, or when the extended repeat area overflows.

---

Note: \* An external request and single address mode are not supported by the H8SX/1520R Group.

---

A block diagram of the DMAC is shown in figure 7.1.

**Figure 7.1 Block Diagram of DMAC**

## 7.2 Register Descriptions

The DMAC has the following registers.

### Channel 0

- DMA source address register\_0 (DSAR\_0)
- DMA destination address register\_0 (DDAR\_0)
- DMA offset register\_0 (DOFR\_0)
- DMA transfer count register\_0 (DTCR\_0)
- DMA block size register\_0 (DBSR\_0)
- DMA mode control register\_0 (DMDR\_0)
- DMA address control register\_0 (DACR\_0)
- DMA module request select register\_0 (DMRSR\_0)

### Channel 1

- DMA source address register\_1 (DSAR\_1)
- DMA destination address register\_1 (DDAR\_1)
- DMA offset register\_1 (DOFR\_1)
- DMA transfer count register\_1 (DTCR\_1)
- DMA block size register\_1 (DBSR\_1)
- DMA mode control register\_1 (DMDR\_1)
- DMA address control register\_1 (DACR\_1)
- DMA module request select register\_1 (DMRSR\_1)

### Channel 2

- DMA source address register\_2 (DSAR\_2)
- DMA destination address register\_2 (DDAR\_2)
- DMA offset register\_2 (DOFR\_2)
- DMA transfer count register\_2 (DTCR\_2)
- DMA block size register\_2 (DBSR\_2)
- DMA mode control register\_2 (DMDR\_2)
- DMA address control register\_2 (DACR\_2)
- DMA module request select register\_2 (DMRSR\_2)

## Channel 3

- DMA source address register\_3 (DSAR\_3)
- DMA destination address register\_3 (DDAR\_3)
- DMA offset register\_3 (DOFR\_3)
- DMA transfer count register\_3 (DTCR\_3)
- DMA block size register\_3 (DBSR\_3)
- DMA mode control register\_3 (DMDR\_3)
- DMA address control register\_3 (DACR\_3)
- DMA module request select register\_3 (DMRSR\_3)

### 7.2.1 DMA Source Address Register (DSAR)

DSAR is a 32-bit readable/writable register that specifies the transfer source address. DSAR updates the transfer source address every time data is transferred. When DDAR is specified as the destination address (the DIRS bit in DACR is 1) in single address mode, DSAR is ignored.

Although DSAR can always be read from by the CPU, it must be read from in longwords and must not be written to while data for the channel is being transferred.

Bit	31	30	29	28	27	26	25	24

### 7.2.2 DMA Destination Address Register (DDAR)

DDAR is a 32-bit readable/writable register that specifies the transfer destination address. DDAR updates the transfer destination address every time data is transferred. When DSAR is specified as the source address (the DIRS bit in DACR is 0) in single address mode, DDAR is ignored.

Although DDAR can always be read from by the CPU, it must be read from in longwords and must not be written to while data for the channel is being transferred.

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

### 7.2.3 DMA Offset Register (DOFR)

DOFR is a 32-bit readable/writable register that specifies the offset to update the source and destination addresses. Although different values are specified for individual channels, the same values must be specified for the source and destination sides of a single channel.

Bit	31	30	29	28	27	26	25	24

## 7.2.4 DMA Transfer Count Register (DTCR)

DTCR is a 32-bit readable/writable register that specifies the size of data to be transferred (total transfer size).

To transfer 1-byte data in total, set H'00000001 in DTCR. When H'00000000 is set in this register, it means that the total transfer size is not specified and data is transferred with the transfer counter stopped (free running mode). When H'FFFFFFFF is set, the total transfer size is 4 Gbytes (4,294,967,295), which is the maximum size. While data is being transferred, this register indicates the remaining transfer size. The value corresponding to its data access size is subtracted every time data is transferred (byte: -1, word: -2, and longword: -4).

Although DTCR can always be read from by the CPU, it must be read from in longwords and must not be written to while data for the channel is being transferred.

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

## 7.2.5 DMA Block Size Register (DBSR)

DBSR specifies the repeat size or block size. DBSR is enabled in repeat transfer mode and block transfer mode and is disabled in normal transfer mode.

Bit	31	30	29	28	27	26	25	24
Bit Name	BKSZH31	BKSZH30	BKSZH29	BKSZH28	BKSZH27	BKSZH26	BKSZH25	BKSZH24
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	23	22	21	20	19	18	17	16
Bit Name	BKSZH23	BKSZH22	BKSZH21	BKSZH20	BKSZH19	BKSZH18	BKSZH17	BKSZH16
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8
Bit Name	BKSZ15	BKSZ14	BKSZ13	BKSZ12	BKSZ11	BKSZ10	BKSZ9	BKSZ8
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Bit Name	BKSZ7	BKSZ6	BKSZ5	BKSZ4	BKSZ3	BKSZ2	BKSZ1	BKSZ0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	BKSZH31 to BKSZH16	Undefined	R/W	Specify the repeat size or block size. When H'0001 is set, the repeat or block size is one byte, one word, or one longword. When H'0000 is set, it means the maximum value (refer to table 7.1). While the DMA is in operation, the setting is fixed.
15 to 0	BKSZ15 to BKSZ0	Undefined	R/W	Indicate the remaining repeat or block size while the DMA is in operation. The value is decremented by 1 every time data is transferred. When the remaining size becomes 0, the value of the BKSZH bits is loaded. Set the same value as the BKSZH bits.

**Table 7.1 Data Access Size, Valid Bits, and Settable Size**

Mode	Data Access Size	BKSZH Valid Bits	BKSZ Valid Bits	Settable Size (Byte)
Repeat transfer and block transfer	Byte	31 to 16	15 to 0	1 to 65,536
	Word			2 to 131,072
	Longword			4 to 262,144

## 7.2.6 DMA Mode Control Register (DMDR)

DMDR controls the DMAC operation.

- DMDR\_0

Bit	Bit Name	Initial Value	R/W	Description
11	TSEIE	0	R/W	<p>Transfer Size Error Interrupt Enable</p> <p>Enables/disables a transfer size error interrupt.</p> <p>When the next transfer is requested while this bit is set to 1 and the contents of the transfer counter is less than the size of data to be transferred at a single transfer request, the DTE bit is cleared to 0. At this time, the ESIF bit is set to 1 to indicate that a transfer size error interrupt has been requested.</p> <p>The sources of a transfer size error are as follows:</p> <ul style="list-style-type: none"> <li>• In normal or repeat transfer mode, the total transfer size set in DTCR is less than the data access size</li> <li>• In block transfer mode, the total transfer size set in DTCR is less than the block size</li> </ul> <p>0: Disables a transfer size error interrupt request 1: Enables a transfer size error interrupt request</p>
10	—	0	R	<p>Reserved</p> <p>This is a read-only bit and cannot be modified.</p>
9	ESIE	0	R/W	<p>Transfer Escape Interrupt Enable</p> <p>Enables/disables a transfer escape end interrupt request. When the ESIF bit is set to 1 with this bit set to 1, a transfer escape end interrupt is requested to the CPU. The transfer end interrupt request is cleared by clearing this bit or the ESIF bit to 0.</p> <p>0: Disables a transfer escape end interrupt 1: Enables a transfer escape end interrupt</p>
8	DTIE	0	R/W	<p>Data Transfer End Interrupt Enable</p> <p>Enables/disables a transfer end interrupt request by the transfer counter. When the DTIF bit is set to 1 with this bit set to 1, a transfer end interrupt is requested to the CPU. The transfer end interrupt request is cleared by clearing this bit or the DTIF bit to 0.</p> <p>0: Disables a transfer end interrupt 1: Enables a transfer end interrupt</p>

Bit	Bit Name	Initial Value	R/W	Description
7	DTF1	0	R/W	Data Transfer Factor 1 and 0
6	DTF0	0	R/W	Select a DMAC activation source. When the on-chip peripheral module setting is selected, the interrupt source should be selected by DMRSR. When the external request setting is selected, the sampling method should be selected by the DREQS bit.  00: Auto request (cycle stealing) 01: Auto request (burst access) 10: On-chip module interrupt 11: External request
5	DTA	0	R/W	Data Transfer Acknowledge  This bit is valid while the DMA transfer is performed by the on-chip module interrupt. This bit decides whether the source flag selected by DMRSR is cleared or not.  0: The source flag is not cleared while the DMA transfer is performed by the on-chip module interrupt. Since the source flag is not cleared by the DMA transfer, it should be cleared by the CPU.  1: The source flag is cleared while the DMA transfer is performed by the on-chip module interrupt. Since the source flag is cleared by the DMA transfer, there is no need to request an interrupt to the CPU.
4, 3	—	All 0	R	Reserved  These are read-only bits and cannot be modified.

---

<b>Bit</b>	<b>Bit Name</b>	<b>Initial Value</b>	<b>R/W</b>	<b>Description</b>
2	DMAP2	0	R/W	DMA Priority Level 2 to 0
1	DMAP1	0	R/W	Select the priority level of the DMAC. When the CPU has priority over the DMAC, the DMAC masks a transfer request and waits for the timing when the CPU priority becomes lower than the DMAC priority. The priority levels can be set to the individual channels. This bit is valid when the CPUPCE bit in CPUPCR is set to 1.
0	DMAP0	0	R/W	000: Priority level 0 (low) 001: Priority level 1 010: Priority level 2 011: Priority level 3 100: Priority level 4 101: Priority level 5 110: Priority level 6 111: Priority level 7 (high)

---

Note: \* Only 0 can be written to, to clear the flag.

## 7.2.7 DMA Address Control Register (DACR)

DACR specifies the operating mode and transfer method.

Bit	31	30	29	28	27	26	25	24
Bit Name	AMS	DIRS	—	—	—	RPTIE	ARS1	ARS0

Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	AMS	0	R/W	Address Mode Select Selects address mode from single or dual address mode. In single address mode, the $\overline{\text{DACK}}$ pin is enabled according to the DACK bit. 0: Dual address mode 1: Single address mode
30	DIRS	0	R/W	Single Address Direction Select Specifies the data transfer direction in single address mode. This bit is ignored in dual address mode. 0: Specifies DSAR as source address 1: Specifies DDAR as destination address
29 to 27	—	0	R/W	Reserved These are read-only bits and cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
26	RPTIE	0	R/W	<p>Repeat Size End Interrupt Enable</p> <p>Enables/disables a repeat size end interrupt request.</p> <p>In repeat transfer mode, when the next transfer is requested after completion of a 1-repeat-size data transfer while this bit is set to 1, the DTE bit in DMDR is cleared to 0. At this time, the ESIF bit in DMDR is set to 1 to indicate that a repeat size end interrupt is requested. Even when the repeat area is not specified (ARS1 = 1 and ARS0 = 0), a repeat size end interrupt after a 1-block data transfer can be requested.</p> <p>In addition, in block transfer mode, when the next transfer is requested after 1-block data transfer while this bit is set to 1, the DTE bit in DMDR is cleared to 0. At this time, the ESIF bit in DMDR is set to 1 to indicate that a repeat size end interrupt is requested.</p> <p>0: Disables a repeat size end interrupt 1: Enables a repeat size end interrupt</p>
25	ARS1	0	R/W	Area Select 1 and 0
24	ARS0	0	R/W	<p>Specify the block area or repeat area in block or repeat transfer mode.</p> <p>00: Specify the block area or repeat area on the source address 01: Specify the block area or repeat area on the destination address 10: Do not specify the block area or repeat area 11: Setting prohibited</p>
23, 22	—	All 0	R	<p>Reserved</p> <p>These are read-only bits and cannot be modified.</p>
21	SAT1	0	R/W	Source Address Update Mode 1 and 0
20	SAT0	0	R/W	<p>Select the update method of the source address (DSAR). When DSAR is not specified as the transfer source in single address mode, this bit is ignored.</p> <p>00: Source address is fixed 01: Source address is updated by adding the offset 10: Source address is updated by adding 1, 2, or 4 according to the data access size 11: Source address is updated by subtracting 1, 2, or 4 according to the data access size</p>

Bit	Bit Name	Initial Value	R/W	Description
19, 18	—	All 0	R	Reserved These are read-only bits and cannot be modified.
17	DAT1	0	R/W	Destination Address Update Mode 1 and 0
16	DAT0	0	R/W	Select the update method of the destination address (DDAR). When DDAR is not specified as the transfer destination in single address mode, this bit is ignored. 00: Destination address is fixed 01: Destination address is updated by adding the offset 10: Destination address is updated by adding 1, 2, or 4 according to the data access size 11: Destination address is updated by subtracting 1, 2, or 4 according to the data access size
15	SARIE	0	R/W	Interrupt Enable for Source Address Extended Area Overflow Enables/disables an interrupt request for an extended area overflow on the source address. When an extended repeat area overflow on the source address occurs while this bit is set to 1, the DTE bit in DMDR is cleared to 0. At this time, the ESIF bit in DMDR is set to 1 to indicate an interrupt by an extended repeat area overflow on the source address is requested. When block transfer mode is used with the extended repeat area function, an interrupt is requested after completion of a 1-block size transfer. When setting the DTE bit in DMDR of the channel for which a transfer has been stopped to 1, the transfer is resumed from the state when the transfer is stopped. When the extended repeat area is not specified, this bit is ignored. 0: Disables an interrupt request for an extended area overflow on the source address 1: Enables an interrupt request for an extended area overflow on the source address
14, 13	—	All 0	R	Reserved These are read-only bits and cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
12	SARA4	0	R/W	Source Address Extended Repeat Area
11	SARA3	0	R/W	<p>Specify the extended repeat area on the source address (DSAR). With the extended repeat area, the specified lower address bits are updated and the remaining upper address bits are fixed. The extended repeat area size is specified from four bytes to 128 Mbytes in units of byte and a power of 2.</p> <p>When the lower address is overflowed from the extended repeat area by address update, the address becomes the start address and the end address of the area for address addition and subtraction, respectively.</p> <p>When an overflow in the extended repeat area occurs with the SARIE bit set to 1, an interrupt can be requested. Table 7.2 shows the settings and areas of the extended repeat area.</p>
10	SARA2	0	R/W	
9	SARA1	0	R/W	
8	SARA0	0	R/W	
7	DARIE	0	R/W	
6, 5	—	All 0	R	<p>Reserved</p> <p>These are read-only bits and cannot be modified.</p>

Bit	Bit Name	Initial Value	R/W	Description
4	DARA4	0	R/W	Destination Address Extended Repeat Area
3	DARA3	0	R/W	Specify the extended repeat area on the destination address (DDAR). With the extended repeat area, the specified lower address bits are updated and the remaining upper address bits are fixed. The extended repeat area size is specified from four bytes to 128 Mbytes in units of byte and a power of 2.  When the lower address is overflowed from the extended repeat area by address update, the address becomes the start address and the end address of the area for address addition and subtraction, respectively.  When an overflow in the extended repeat area occurs with the DARIE bit set to 1, an interrupt can be requested. Table 7.2 shows the settings and areas of the extended repeat area.
2	DARA2	0	R/W	
1	DARA1	0	R/W	
0	DARA0	0	R/W	

**Table 7.2 Settings and Areas of Extended Repeat Area**

<b>SARA4 to SARA0 or DARA4 to DARA0</b>	<b>Extended Repeat Area</b>
00000	Not specified
00001	2 bytes specified as extended repeat area by the lower 1 bit of the address
00010	4 bytes specified as extended repeat area by the lower 2 bits of the address
00011	8 bytes specified as extended repeat area by the lower 3 bits of the address
00100	16 bytes specified as extended repeat area by the lower 4 bits of the address
00101	32 bytes specified as extended repeat area by the lower 5 bits of the address
00110	64 bytes specified as extended repeat area by the lower 6 bits of the address
00111	128 bytes specified as extended repeat area by the lower 7 bits of the address
01000	256 bytes specified as extended repeat area by the lower 8 bits of the address

×: Don't care

## 7.2.8 DMA Module Request Select Register (DMRSR)

DMRSR is an 8-bit readable/writable register that specifies the on-chip module interrupt source. The vector number of the interrupt source is specified in eight bits. However, 0 is regarded as no interrupt source. For the vector numbers of the interrupt sources, refer to table 7.4.

Bit	7	6	5	4	3	2	1	0
Bit Name								
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

## 7.3 Transfer Modes

Table 7.3 shows the DMAC transfer modes. The transfer modes can be specified to the individual channels.

**Table 7.3 Transfer Modes**

Address Mode	Transfer mode	Activation Source	Common Function	Address Register	
				Source	Destination
Dual address	<ul style="list-style-type: none"> <li>Normal transfer</li> <li>Repeat transfer</li> <li>Block transfer</li> </ul> Repeat or block size = 1 to 65,536 bytes, 1 to 65,536 words, or 1 to 65,536 longwords	<ul style="list-style-type: none"> <li>Auto request (activated by CPU)</li> <li>On-chip module interrupt</li> <li>External request</li> </ul>	<ul style="list-style-type: none"> <li>Total transfer size: 1 to 4 Gbytes or not specified</li> <li>Offset addition</li> <li>Extended repeat area function</li> </ul>	DSAR	DDAR
Single address	<ul style="list-style-type: none"> <li>Instead of specifying the source or destination address registers, data is directly transferred from/to the external device using the <math>\overline{DACK}</math> pin</li> <li>The same settings as above are available other than address register setting (e.g., above transfer modes can be specified)</li> <li>One transfer can be performed in one bus cycle (the types of transfer modes are the same as those of dual address modes)</li> </ul>			$\overline{DSAR}/\overline{DACK}$	$\overline{DACK}/\overline{DDAR}$

When the auto request setting is selected as the activation source, the cycle stealing or burst access can be selected. When the total transfer size is not specified (DTCR = H'00000000), the transfer counter is stopped and the transfer is continued without the limitation of the transfer count.

## 7.4 Operations

### 7.4.1 Address Modes

#### (1) Dual Address Mode

In dual address mode, the transfer source address is specified in DSAR and the transfer destination address is specified in DDAR. A transfer at a time is performed in two bus cycles (when the data bus width is less than the data access size or the access address is not aligned with the boundary of the data access size, the number of bus cycles are needed more than two because one bus cycle is divided into multiple bus cycles).

In the first bus cycle, data at the transfer source address is read and in the next cycle, the read data is written to the transfer destination address.

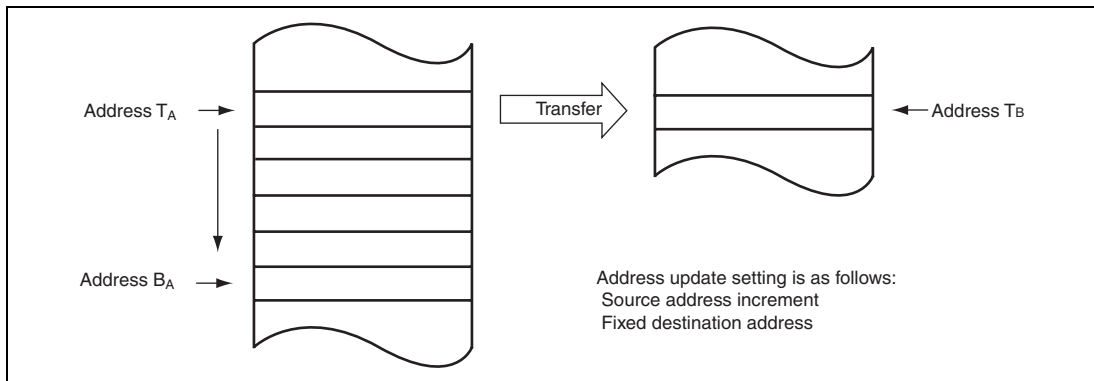

The read and write cycles are not separated. Other bus cycles (bus cycle by other bus masters, refresh cycle, and external bus release cycle) are not generated between read and write cycles.

The  $\overline{\text{TEND}}$  signal output is enabled or disabled by the TENDE bit in DMDR. The  $\overline{\text{TEND}}$  signal is output in two bus cycles. When an idle cycle is inserted before the bus cycle, the  $\overline{\text{TEND}}$  signal is also output in the idle cycle. The  $\overline{\text{DACK}}$  signal is not output.

Figure 7.2 shows an example of the signal timing in dual address mode and figure 7.3 shows the operation in dual address mode.

**Figure 7.2 Example of Signal Timing in Dual Address Mode**

**Figure 7.3 Operations in Dual Address Mode**

## (2) Single Address Mode

In single address mode, data between an external device and an external memory is directly transferred using the  $\overline{\text{DACK}}$  pin instead of DSAR or DDAR. A transfer at a time is performed in one bus cycle. In this mode, the data bus width must be the same as the data access size. For details on the data bus width, see section 6, Bus Controller (BSC).

The DMAC accesses an external device as the transfer source or destination by outputting the strobe signal to the external device ( $\overline{\text{DACK}}$ ) and accesses the other transfer target by outputting the address. Accordingly, the DMA transfer is performed in one bus cycle. Figure 7.4 shows an example of a transfer between an external memory and an external device with the  $\overline{\text{DACK}}$  pin. In this example, the external device outputs data on the data bus and the data is written to the external memory in the same bus cycle.

The transfer direction is decided by the DIRS bit in DACR which specifies an external device with the  $\overline{\text{DACK}}$  pin as the transfer source or destination. When DIRS = 0, data is transferred from an external memory (DSAR) to an external device with the  $\overline{\text{DACK}}$  pin. When DIRS = 1, data is transferred from an external device with the  $\overline{\text{DACK}}$  pin to an external memory (DDAR). The settings of registers which are not used as the transfer source or destination are ignored.

The  $\overline{\text{DACK}}$  signal output is enabled in single address mode by the DACKE bit in DMDR. The  $\overline{\text{DACK}}$  signal is low active.

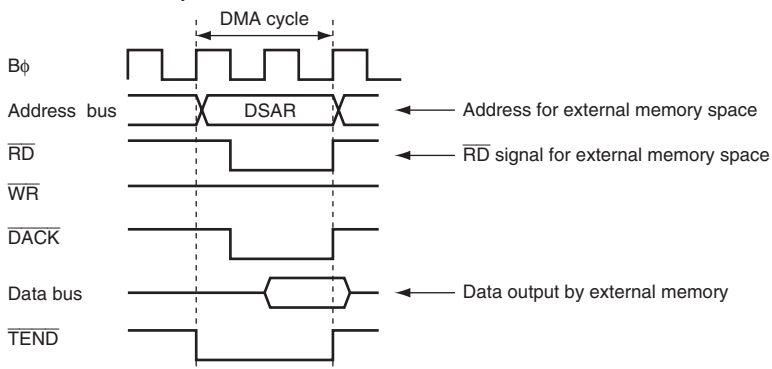

The  $\overline{\text{TEND}}$  signal output is enabled or disabled by the TENDE bit in DMDR. The  $\overline{\text{TEND}}$  signal is output in one bus cycle. When an idle cycle is inserted before the bus cycle, the  $\overline{\text{TEND}}$  signal is also output in the idle cycle.

Figure 7.5 shows an example of timing charts in single address mode and figure 7.6 shows an example of operation in single address mode.

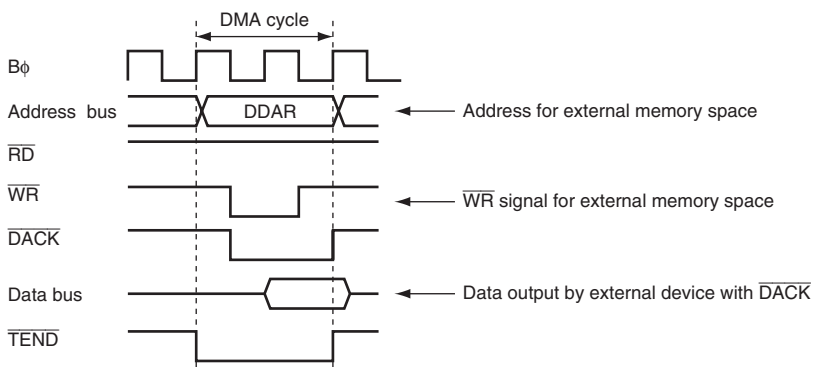

**Figure 7.4 Data Flow in Single Address Mode**

Transfer from external memory to external device with  $\overline{DACK}$

Transfer from external device with  $\overline{DACK}$  to external memory

**Figure 7.5 Example of Signal Timing in Single Address Mode**

**Figure 7.6 Operations in Single Address Mode**

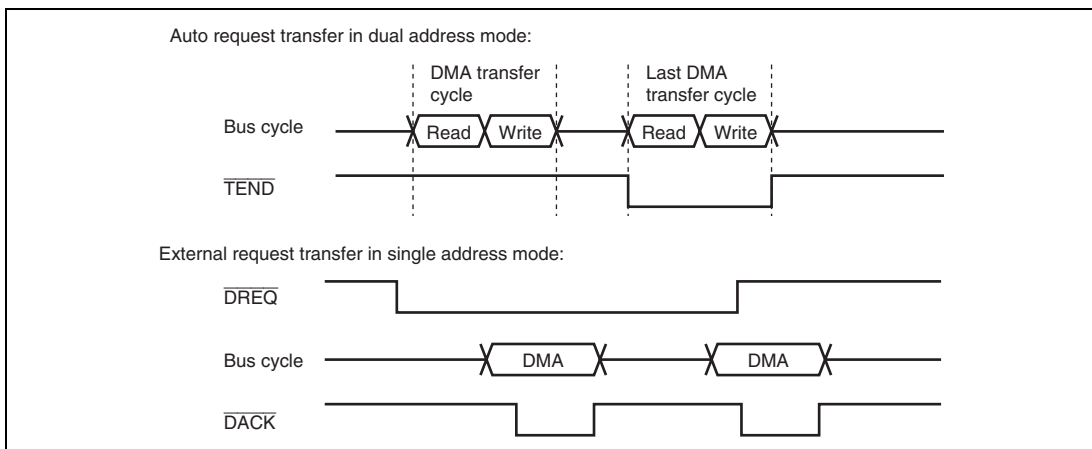

## 7.4.2 Transfer Modes

### (1) Normal Transfer Mode

In normal transfer mode, one data access size of data is transferred at a single transfer request. Up to 4 Gbytes can be specified as a total transfer size by DTCR. DBSR is ignored in normal transfer mode.

The  $\overline{TEND}$  signal is output only in the last DMA transfer. The  $\overline{DACK}$  signal is output every time a transfer request is received and a transfer starts.

Figure 7.7 shows an example of the signal timing in normal transfer mode and figure 7.8 shows the operation in normal transfer mode.

**Figure 7.7 Example of Signal Timing in Normal Transfer Mode**

**Figure 7.8 Operations in Normal Transfer Mode**

## (2) Repeat Transfer Mode

In repeat transfer mode, one data access size of data is transferred at a single transfer request. Up to 4 Gbytes can be specified as a total transfer size by DTCR. The repeat size can be specified in DBSR up to  $65536 \times$  data access size.

The repeat area can be specified for the source or destination address side by bits ARS1 and ARS0 in DACR. The address specified as the repeat area returns to the transfer start address when the repeat size of transfers is completed. This operation is repeated until the total transfer size specified in DTCR is completed. When H'00000000 is specified in DTCR, it is regarded as the free running mode and repeat transfer is continued until the DTE bit in DMDR is cleared to 0.

In addition, a DMA transfer can be stopped and a repeat size end interrupt can be requested to the CPU when the repeat size of transfers is completed. When the next transfer is requested after completion of a 1-repeat size data transfer while the RPTIE bit is set to 1, the DTE bit in DMDR is cleared to 0 and the ESIF bit in DMDR is set to 1 to complete the transfer. At this time, an interrupt is requested to the CPU when the ESIE bit in DMDR is set to 1.

The timings of the  $\overline{TEND}$  and  $\overline{DACK}$  signals are the same as in normal transfer mode.

Figure 7.9 shows the operation in repeat transfer mode while dual address mode is set.

When the repeat area is specified as neither source nor destination address side, the operation is the same as the normal transfer mode operation shown in figure 7.8. In this case, a repeat size end interrupt can also be requested to the CPU when the repeat size of transfers is completed.

**Figure 7.9 Operations in Repeat Transfer Mode**

### (3) Block Transfer Mode

In block transfer mode, one block size of data is transferred at a single transfer request. Up to 4 Gbytes can be specified as total transfer size by DTCR. The block size can be specified in DBSR up to  $65536 \times$  data access size.

While one block of data is being transferred, transfer requests from other channels are suspended. When the transfer is completed, the bus is released to the other bus master.

The block area can be specified for the source or destination address side by bits ARS1 and ARS0 in DACR. The address specified as the block area returns to the transfer start address when the block size of data is completed. When the block area is specified as neither source nor destination address side, the operation continues without returning the address to the transfer start address. A repeat size end interrupt can be requested.

The  $\overline{\text{TEND}}$  signal is output every time 1-block data is transferred in the last DMA transfer cycle. When the external request is selected as an activation source, the low level detection of the  $\overline{\text{DREQ}}$  signal ( $\text{DREQS} = 0$ ) should be selected.

When an interrupt request by an extended repeat area overflow is used in block transfer mode, settings should be selected carefully. For details, see section 7.4.5, Extended Repeat Area Function.

Figure 7.10 shows an example of the DMA transfer timing in block transfer mode. The transfer conditions are as follows:

- Address mode: single address mode
- Data access size: byte
- 1-block size: three bytes

The block transfer mode operations in single address mode and in dual address mode are shown in figures 7.11 and 7.12, respectively.

**Figure 7.10 Operations in Block Transfer Mode**

**Figure 7.11 Operation in Single Address Mode in Block Transfer Mode  
(Block Area Specified)**

**Figure 7.12 Operation in Dual Address Mode in Block Transfer Mode  
(Block Area Not Specified)**

### 7.4.3 Activation Sources

The DMAC is activated by an auto request, an on-chip module interrupt, and an external request. The activation source is specified by bits DTF1 and DTF0 in DMDR.

#### (1) Activation by Auto Request

The auto request activation is used when a transfer request from an external device or an on-chip peripheral module is not generated such as a transfer between memory and memory or between memory and an on-chip peripheral module which does not request a transfer. A transfer request is automatically generated inside the DMAC. In auto request activation, setting the DTE bit in DMDR starts a transfer. The bus mode can be selected from cycle stealing and burst modes.

#### (2) Activation by On-Chip Module Interrupt

An interrupt request from an on-chip peripheral module (on-chip peripheral module interrupt) is used as a transfer request. When a DMA transfer is enabled ( $DTE = 1$ ), the DMA transfer is started by an on-chip module interrupt.

The activation source of the on-chip module interrupt is selected by the DMA module request select register (DMRSR). The activation sources are specified to the individual channels. Table 7.4 is a list of on-chip module interrupts for the DMAC.

The interrupt request selected as an activation source can simultaneously generate interrupt requests to the CPU. For details, see section 5, Interrupt Controller.

The DMAC receives interrupt requests by on-chip peripheral modules independent of the interrupt controller. Therefore, the DMAC is not affected by priority given in the interrupt controller.

When the DMAC is activated with  $DTA = 1$ , the interrupt request flag is automatically cleared by a DMA transfer. If multiple channels use a single transfer request as an activation source, when the channel having priority is activated, the interrupt request flag is cleared. In this case, other channels may not be activated because the transfer request is not held in the DMAC.

When the DMAC is activated with  $DTA = 0$ , the interrupt request flag is not cleared by the DMAC. It should be cleared by the CPU.

When an activation source is selected while  $DTE = 0$ , the activation source does not request a transfer to the DMAC. It requests an interrupt to the CPU.

In addition, make sure that an interrupt request flag as an on-chip module interrupt source is cleared to 0 before writing 1 to the DTE bit.

**Table 7.4 List of On-chip module interrupts to DMAC**

<b>On-Chip Module Interrupt Source</b>	<b>On-Chip Module</b>	<b>DMRSR (Vector Number)</b>
ADI0 (A/D conversion end interrupt)	A/D_0	86
ADI1 (A/D conversion end interrupt)	A/D_1	87
TGI0A (TGI0A input capture/compare match)	TPU_0	88
TGI1A (TGI1A input capture/compare match)	TPU_1	93
TGI2A (TGI2A input capture/compare match)	TPU_2	97
TGI3A (TGI3A input capture/compare match)	TPU_3	101
RXI3 (receive data full interrupt for SCI channel 3)	SCI_3	157
TXI3 (transmit data empty interrupt for SCI channel 3)	SCI_3	158
RXI4 (receive data full interrupt for SCI channel 4)	SCI_4	161
TXI4 (transmit data empty interrupt for SCI channel 4)	SCI_4	162
TGI6A (TGI6A input capture/compare match)	TPU_6	164
TGI7A (TGI7A input capture/compare match)	TPU_7	169
TGI8A (TGI8A input capture/compare match)	TPU_8	173
TGI9A (TGI9A input capture/compare match)	TPU_9	177
TGI10A (TGI10A input capture/compare match)	TPU_10	182
TGI11A (TGI11A input capture/compare match)	TPU_11	188
RM0 (message reception in Mailbox 0)	RCAN-ET	221
SSRXI0 (receive data full interrupt for SSU channel 0)	SSU_0	228
SSTXI0 (transmit data empty interrupt or transmit end for SSU channel 0)	SSU_0	229
SSRXI1 (receive data full interrupt for SSU channel 1)	SSU_1	232
SSTXI1 (transmit data empty interrupt or transmit end for SSU channel 1)	SSU_1	233
SSRXI2 (receive data full interrupt for SSU channel 2)	SSU_2	236
SSTXI2 (transmit data empty interrupt or transmit end for SSU channel 2)	SSU_2	237

### (3) Activation by External Request

A transfer is started by a transfer request signal ( $\overline{\text{DREQ}}$ ) from an external device. When a DMA transfer is enabled ( $\text{DTE} = 1$ ), the DMA transfer is started by the  $\overline{\text{DREQ}}$  assertion.

A transfer request signal is input to the  $\overline{\text{DREQ}}$  pin. The  $\overline{\text{DREQ}}$  signal is detected on the falling edge or low level. Whether the falling edge or low level detection is used is selected by the  $\text{DREQS}$  bit in  $\text{DMDR}$ . To perform a block transfer, select the low level detection.

When an external request is selected as an activation source, clear the  $\text{DDR}$  bit to 0 and set the  $\text{ICR}$  bit to 1 for the corresponding pin. For details, see section 8, I/O Ports.

When a DMA transfer between on-chip peripheral modules is performed, select an activation source from the auto request and on-chip module interrupt (the external request cannot be used).

#### 7.4.4 Bus Access Modes

There are two types of bus access modes: cycle stealing and burst.

When an activation source is the auto request, the cycle stealing or burst mode is selected by bit  $\text{DTF0}$  in  $\text{DMDR}$ . When an activation source is the on-chip module interrupt or external request, the cycle stealing mode is selected.

##### (1) Cycle Stealing Mode

In cycle stealing mode, the  $\text{DMAC}$  releases the bus every time one unit of transfers (byte, word, longword, or 1-block size) is completed. After that, when a transfer is requested, the  $\text{DMAC}$  obtains the bus to transfer 1-unit data and then releases the bus on completion of the transfer. This operation is continued until the transfer end condition is satisfied.

When a transfer is requested to another channel during a DMA transfer, the  $\text{DMAC}$  releases the bus and then transfers data for the requested channel. For details on operations when a transfer is requested to multiple channels, see section 7.4.8, Priority of Channels.

Figure 7.13 shows an example of timing in cycle stealing mode. The transfer conditions are as follows:

- Address mode: Single address mode
- Sampling method of the  $\overline{\text{DREQ}}$  signal: Low level detection

**Figure 7.13 Example of Timing in Cycle Stealing Mode**

## (2) Burst Mode

In burst mode, once it takes the bus, the DMAC continues a transfer without releasing the bus until the transfer end condition is satisfied. Even if a transfer is requested from another channel having priority, the transfer is not stopped once it is started. The DMAC releases the bus in the next cycle after the transfer for the channel in burst mode is completed. This is similarly to operation in cycle stealing mode. However, setting the IBCCS bit in IBCR of the bus controller makes the DMAC release the bus to pass the bus to another bus master.

In block transfer mode, the burst mode setting is ignored (operation is the same as that in burst mode during one block of transfers). The DMAC is always operated in cycle stealing mode.

Clearing the DTE bit in DMDR stops a DMA transfer. A transfer requested before the DTE bit is cleared to 0 by the DMAC is executed. When an interrupt by a transfer size error, a repeat size end, or an extended repeat area overflow occurs, the DTE bit is cleared to 0 and the transfer ends.

Figure 7.14 shows an example of timing in burst mode.

**Figure 7.14 Example of Timing in Burst Mode**

### 7.4.5 Extended Repeat Area Function

The source and destination address sides can be specified as the extended repeat area. The contents of the address register repeat addresses within the area specified as the extended repeat area. For example, to use a ring buffer as the transfer target, the contents of the address register should return to the start address of the buffer every time the contents reach the end address of the buffer (overflow on the ring buffer address). This operation can automatically be performed using the extended repeat area function of the DMAC.

The extended repeat areas can be specified independently to the source address register (DSAR) and destination address register (DDAR).

The extended repeat area on the source address is specified by bits SARA4 to SARA0 in DACR. The extended repeat area on the destination address is specified by bits DARA4 to DARA0 in DACR. The extended repeat area sizes for each side can be specified independently.

A DMA transfer is stopped and an interrupt by an extended repeat area overflow can be requested to the CPU when the contents of the address register reach the end address of the extended repeat area. When an overflow on the extended repeat area set in DSAR occurs while the SARIE bit in DACR is set to 1, the ESIF bit in DMDR is set to 1 and the DTE bit in DMDR is cleared to 0 to stop the transfer. At this time, if the ESIE bit in DMDR is set to 1, an interrupt by an extended repeat area overflow is requested to the CPU. When the DARIE bit in DACR is set to 1, an overflow on the extended repeat area set in DDAR occurs, meaning that the destination side is a target. During the interrupt handling, setting the DTE bit in DMDR resumes the transfer.

Figure 7.15 shows an example of the extended repeat area operation.

When the area represented by the lower three bits of DSAR (eight bytes) is specified as the extended repeat area (SARA4 to SARA0 = B'00011)

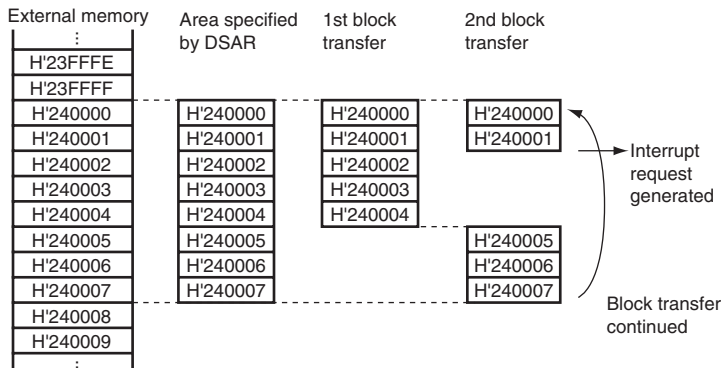

**Figure 7.15 Example of Extended Repeat Area Operation**

When an interrupt by an extended repeat area overflow is used in block transfer mode, the following should be taken into consideration.

When a transfer is stopped by an interrupt by an extended repeat area overflow, the address register must be set so that the block size is a power of 2 or the block size boundary is aligned with the extended repeat area boundary. When an overflow on the extended repeat area occurs during a transfer of one block, the interrupt by the overflow is suspended and the transfer overruns.

Figure 7.16 shows examples when the extended repeat area function is used in block transfer mode.

When the are represented by the lower three bits (eight bytes) of DSAR are specified as the extended repeat area (SARA4 to SARA0 = 3) and the block size in block transfer mode is specified to 5 (bits 23 to 16 in DTCCR = 5).

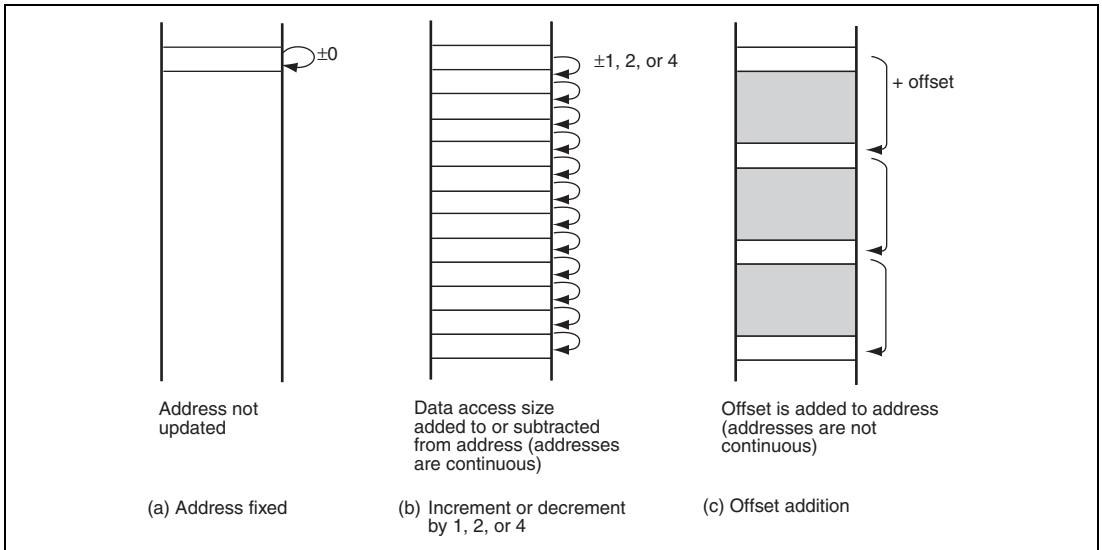

**Figure 7.16 Example of Extended Repeat Area Function in Block Transfer Mode**

### 7.4.6 Address Update Function using Offset

The source and destination addresses are updated by fixing, increment/decrement by 1, 2, or 4, or offset addition. When the offset addition is selected, the offset specified by the offset register (DOFR) is added to the address every time the DMAC transfers the data access size of data. This function realizes a data transfer where addresses are allocated to separated areas.

Figure 7.17 shows the address update method.

**Figure 7.17 Address Update Method**

In item (a), Address fixed, the transfer source or destination address is not updated indicating the same address.

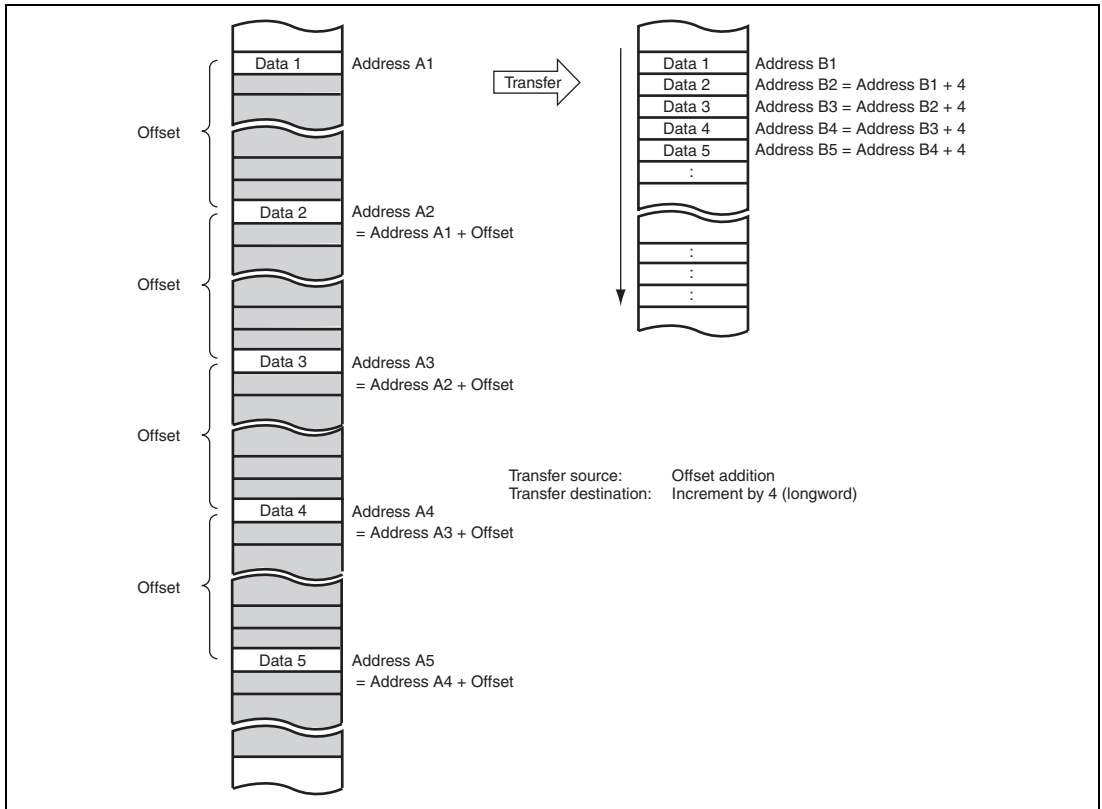

In item (b), Increment or decrement by 1, 2, or 4, the transfer source or destination address is incremented or decremented by the value according to the data access size at each transfer. Byte, word, or longword can be specified as the data access size. The value of 1 for byte, 2 for word, and 4 for longword is used for updating the address. This operation realizes the data transfer placed in consecutive areas.

In item (c), Offset addition, the address update does not depend on the data access size. The offset specified by DOFR is added to the address every time the DMAC transfers data of the data access size.

The address is calculated by the offset set in DOFR and the contents of DSAR and DDAR. Although the DMAC calculates only addition, an offset subtraction can be realized by setting the negative value in DOFR. In this case, the negative value must be 2's complement.

### (1) Basic Transfer Using Offset

Figure 7.18 shows a basic operation of a transfer using the offset addition.

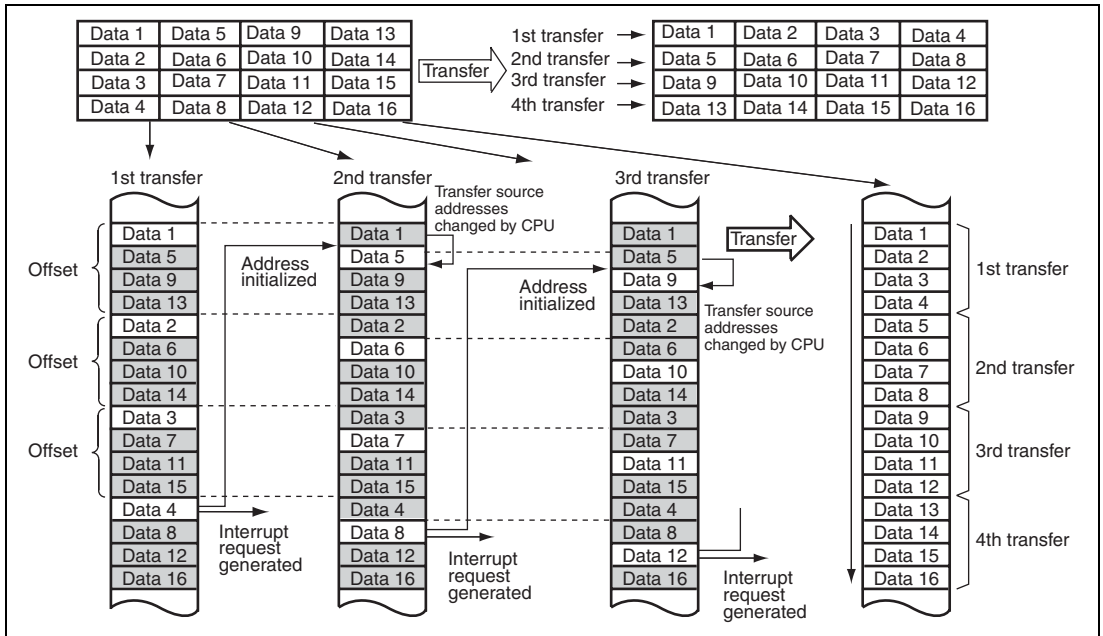

**Figure 7.18 Operation of Offset Addition**

In figure 7.18, the offset addition is selected as the transfer source address update and increment or decrement by 1, 2, or 4 is selected as the transfer destination address. The address update means that data at the address which is away from the previous transfer source address by the offset is read from. The data read from the address away from the previous address is written to the consecutive area in the destination side.

## (2) XY Conversion Using Offset

Figure 7.19 shows the XY conversion using the offset addition in repeat transfer mode.

**Figure 7.19 XY Conversion Operation Using Offset Addition in Repeat Transfer Mode**

In figure 7.19, the source address side is specified to the repeat area by DACR and the offset addition is selected. The offset value is set to  $4 \times$  data access size (when the data access size is longword, H'00000010 is set in DOFR, as an example). The repeat size is set to  $4 \times$  data access size (when the data access size is longword, the repeat size is set to  $4 \times 4 = 16$  bytes, as an example). The increment or decrement by 1, 2, or 4 is specified as the transfer destination address. A repeat size end interrupt is requested when the repeat size of transfers is completed.

When a transfer starts, the transfer source address is added to the offset every time data is transferred. The transfer data is written to the destination continuous addresses. When data 4 is transferred meaning that the repeat size of transfers is completed, the transfer source address returns to the transfer start address (address of data 1 on the transfer source) and a repeat size end interrupt is requested. While this interrupt stops the transfer temporarily, the contents of DSAR are written to the address of data 5 by the CPU (when the data access size is longword, write the data 1 address + 4). When the DTE bit in DMDR is set to 1, the transfer is resumed from the state when the transfer is stopped. Accordingly, operations are repeated and the transfer source data is transposed to the destination area (XY conversion).

Figure 7.29 shows a flowchart of the XY conversion.

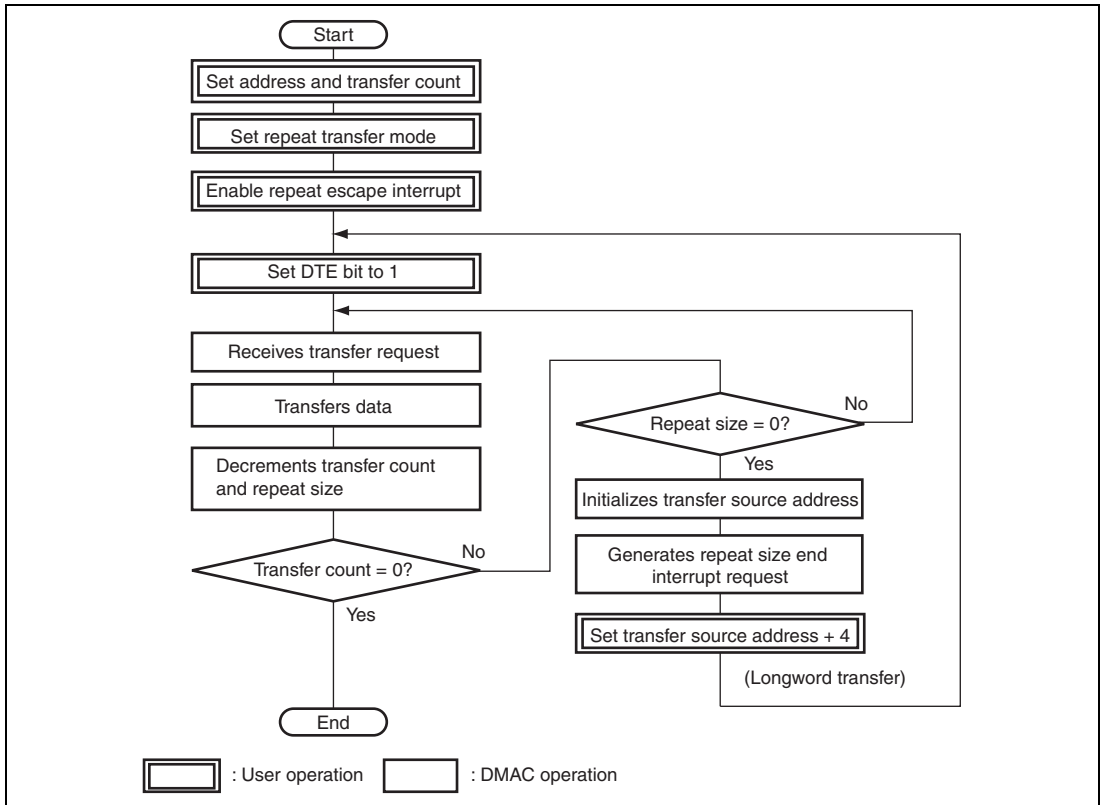

Figure 7.20 XY Conversion Flowchart Using Offset Addition in Repeat Transfer Mode

### (3) Offset Subtraction

When setting the negative value in DOFR, the offset value must be 2's complement. The 2's complement is obtained by the following formula.

$$2\text{'s complement of offset} = 1 + \sim\text{offset} (\sim: \text{bit inversion})$$

Example: 2's complement of H'0001FFFF  
 = H'FFFE0000 + H'00000001  
 = H'FFFE0001

The value of 2's complement can be obtained by the NEG.L instruction.

### 7.4.7 Register during DMA Transfer

The DMAC registers are updated by a DMA transfer. The value to be updated differs according to the other settings and transfer state. The registers to be updated are DSAR, DDAR, DTCCR, bits BKSZH and BKSZ in DBSR, and the DTE, ACT, ERRF, ESIF, and DTIF bits in DMDR.

#### (1) DMA Source Address Register

When the transfer source address set in DSAR is accessed, the contents of DSAR are output and then are updated to the next address.

The increment or decrement can be specified by bits SAT1 and SAT0 in DACR. When SAT1 and SAT0 = B'00, the address is fixed. When SAT1 and SAT0 = B'01, the address is added with the offset. When SAT1 and SAT0 = B'10, the address is incremented. When SAT1 and SAT0 = B'11, the address is decremented. The size of increment or decrement depends on the data access size.

The data access size is specified by bits DTSZ1 and DTSZ0 in DMDR. When DTSZ1 and DTSZ0 = B'00, the data access size is byte and the address is incremented or decremented by 1. When DTSZ1 and DTSZ0 = B'01, the data access size is word and the address is incremented or decremented by 2. When DTSZ1 and DTSZ0 = B'10, the data access size is longword and the address is incremented or decremented by 4. Even if the access data size of the source address is word or longword, when the source address is not aligned with the word or longword boundary, the read bus cycle is divided into byte or word cycles. While data of one word or one longword is being read, the size of increment or decrement is changing according to the actual data access size, for example, +1 or +2 for byte or word data. After one word or one longword of data is read, the address when the read cycle is started is incremented or decremented by the value according to bits SAT1 and SAT0.

In block or repeat transfer mode, when the block or repeat size of data transfers is completed while the block or repeat area is specified to the source address side, the source address returns to the transfer start address and is not affected by the address update.

When the extended repeat area is specified to the source address side, operation follows the setting. The upper address bits are fixed and is not affected by the address update.

While data is being transferred, DSAR must be accessed in longwords. If the upper word and lower word are read separately, incorrect data may be read from since the contents of DSAR during the transfer may be updated regardless of the access by the CPU. Moreover, DSAR for the channel being transferred must not be written to.

## (2) DMA Destination Address Register

When the transfer destination address set in DDAR is accessed, the contents of DDAR are output and then are updated to the next address.

The increment or decrement can be specified by bits DAT1 and DAT0 in DACR. When DAT1 and DAT0 = B'00, the address is fixed. When DAT1 and DAT0 = B'01, the address is added with the offset. When DAT1 and DAT0 = B'10, the address is incremented. When DAT1 and DAT0 = B'11, the address is decremented. The incrementing or decrementing size depends on the data access size.

The data access size is specified by bits DTSZ1 and DTSZ0 in DMDR. When DTSZ1 and DTSZ0 = B'00, the data access size is byte and the address is incremented or decremented by 1. When DTSZ1 and DTSZ0 = B'01, the data access size is word and the address is incremented or decremented by 2. When DTSZ1 and DTSZ0 = B'10, the data access size is longword and the address is incremented or decremented by 4. Even if the access data size of the destination address is word or longword, when the destination address is not aligned with the word or longword boundary, the write bus cycle is divided into byte and word cycles. While one word or one longword of data is being written, the incrementing or decrementing size is changing according to the actual data access size, for example, +1 or +2 for byte or word data. After the one word or one longword of data is written, the address when the write cycle is started is incremented or decremented by the value according to bits SAT1 and SAT0.

In block or repeat transfer mode, when the block or repeat size of data transfers is completed while the block or repeat area is specified to the destination address side, the destination address returns to the transfer start address and is not affected by the address update.

When the extended repeat area is specified to the destination address side, operation follows the setting. The upper address bits are fixed and is not affected by the address update.

While data is being transferred, DDAR must be accessed in longwords. If the upper word and lower word are read separately, incorrect data may be read from since the contents of DDAR during the transfer may be updated regardless of the access by the CPU. Moreover, DDAR for the channel being transferred must not be written to.

## (3) DMA Transfer Count Register (DTCR)

A DMA transfer decrements the contents of DTCR by the transferred bytes. When byte data is transferred, DTCR is decremented by 1. When word data is transferred, DTCR is decremented by 2. When longword data is transferred, DTCR is decremented by 4. However, when DTCR = 0, the contents of DTCR are not changed since the number of transfers is not counted.

While data is being transferred, all the bits of DTCR may be changed. DTCR must be accessed in longwords. If the upper word and lower word are read separately, incorrect data may be read from since the contents of DTCR during the transfer may be updated regardless of the access by the CPU. Moreover, DTCR for the channel being transferred must not be written to.

When a conflict occurs between the address update by DMA transfer and write access by the CPU, the CPU has priority. When a conflict occurs between change from 1, 2, or 4 to 0 in DTCR and write access by the CPU (other than 0), the CPU has priority in writing to DTCR. However, the transfer is stopped.

#### **(4) DMA Block Size Register (DBSR)**

DBSR is enabled in block or repeat transfer mode. Bits 31 to 16 in DBSR function as BKSZH and bits 15 to 0 in DBSR function as BKSZ. The BKSZH bits (16 bits) store the block size and repeat size and its value is not changed. The BKSZ bits (16 bits) function as a counter for the block size and repeat size and its value is decremented every transfer by 1. When the BKSZ value is to change from 1 to 0 by a DMA transfer, 0 is not stored but the BKSZH value is loaded into the BKSZ bits.

Since the upper 16 bits of DBSR are not updated, DBSR can be accessed in words.

DBSR for the channel being transferred must not be written to.

#### **(5) DTE Bit in DMDR**

Although the DTE bit in DMDR enables or disables data transfer by the CPU write access, it is automatically cleared to 0 according to the DMA transfer state by the DMAC.

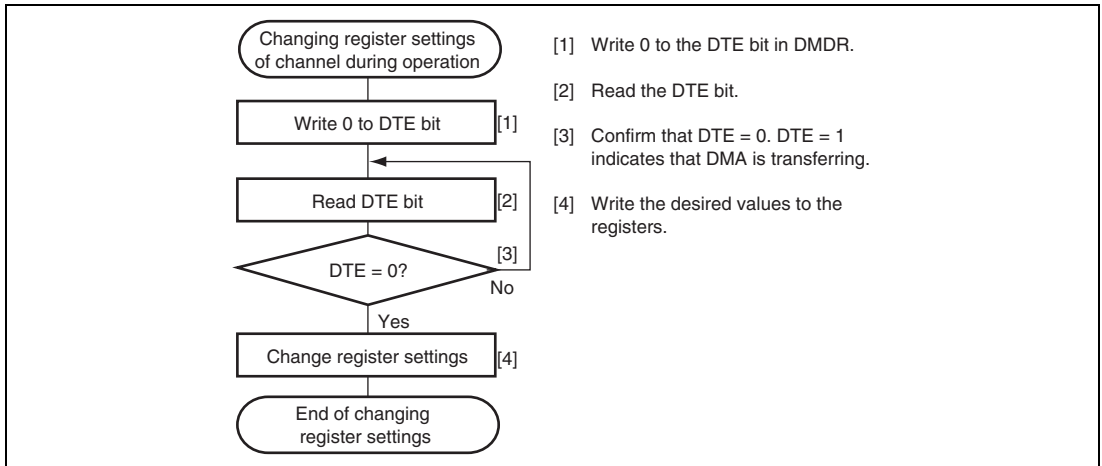

The conditions for clearing the DTE bit by the DMAC are as follows:

- When the total size of transfers is completed
- When a transfer is completed by a transfer size error interrupt
- When a transfer is completed by a repeat size end interrupt
- When a transfer is completed by an extended repeat area overflow interrupt
- When a transfer is stopped by an NMI interrupt
- When a transfer is stopped by an address error
- Reset state
- Hardware standby mode
- When a transfer is stopped by writing 0 to the DTE bit

Writing to the registers for the channels when the corresponding DTE bit is set to 1 is prohibited (except for the DTE bit). When changing the register settings after writing 0 to the DTE bit, confirm that the DTE bit has been cleared to 0.

Figure 7.21 show the procedure for changing the register settings for the channel being transferred.

**Figure 7.21 Procedure for Changing Register Setting For Channel being Transferred**

## (6) ACT Bit in DMDR

The ACT bit in DMDR indicates whether the DMAC is in the idle or active state. When DTE = 0 or DTE = 1 and the DMAC is waiting for a transfer request, the ACT bit is 0. Otherwise (the DMAC is in the active state), the ACT bit is 1. When individual transfers are stopped by writing 0 and the transfer is not completed, the ACT bit retains 1.

In block transfer mode, even if individual transfers are stopped by writing 0 to the DTE bit, the 1-block size of transfers is not stopped. The ACT bit retains 1 from writing 0 to the DTE bit to completion of a 1-block size transfer.

In burst mode, up to three times of DMA transfer are performed from the cycle in which the DTE bit is written to 0. The ACT bit retains 1 from writing 0 to the DTE bit to completion of DMA transfer.

### **(7) ERRF Bit in DMDR**

When an address error or an NMI interrupt occur, the DMAC clears the DTE bits for all the channels to stop a transfer. In addition, it sets the ERRF bit in DMDR\_0 to 1 to indicate that an address error or an NMI interrupt has occurred regardless of whether or not the DMAC is in operation.

### **(8) ESIF Bit in DMDR**

When an interrupt by a transfer size error, a repeat size end, or an extended repeat area overflow is requested, the ESIF bit in DMDR is set to 1. When both the ESIF and ESIE bits are set to 1, a transfer escape interrupt is requested to the CPU.

The ESIF bit is set to 1 when the ACT bit in DMDR is cleared to 0 to stop a transfer after the bus cycle of the interrupt source is completed.

The ESIF bit is automatically cleared to 0 and a transfer request is cleared if the transfer is resumed by setting the DTE bit to 1 during interrupt handling.

For details on interrupts, see section 7.7, Interrupt Sources.

### **(9) DTIF Bit in DMDR**

The DTIF bit in DMDR is set to 1 after the total transfer size of transfers is completed. When both the DTIF and DTIE bits in DMDR are set to 1, a transfer end interrupt by the transfer counter is requested to the CPU.

The DTIF bit is set to 1 when the ACT bit in DMDR is cleared to 0 to stop a transfer after the bus cycle is completed.

The DTIF bit is automatically cleared to 0 and a transfer request is cleared if the transfer is resumed by setting the DTE bit to 1 during interrupt handling.

For details on interrupts, see section 7.7, Interrupt Sources.

### 7.4.8 Priority of Channels

The channels of the DMAC are given following priority levels: channel 0 > channel 1 > channel 2 > channel 3. Table 7.5 shows the priority levels among the DMAC channels.

**Table 7.5 Priority among DMAC Channels**

Channel	Priority
Channel 0	High
Channel 1	
Channel 2	
Channel 3	Low

The channel having highest priority other than the channel being transferred is selected when a transfer is requested from other channels. The selected channel starts the transfer after the channel being transferred releases the bus. At this time, when a bus master other than the DMAC requests the bus, the cycle for the bus master is inserted.

In a burst transfer or a block transfer, channels are not switched.

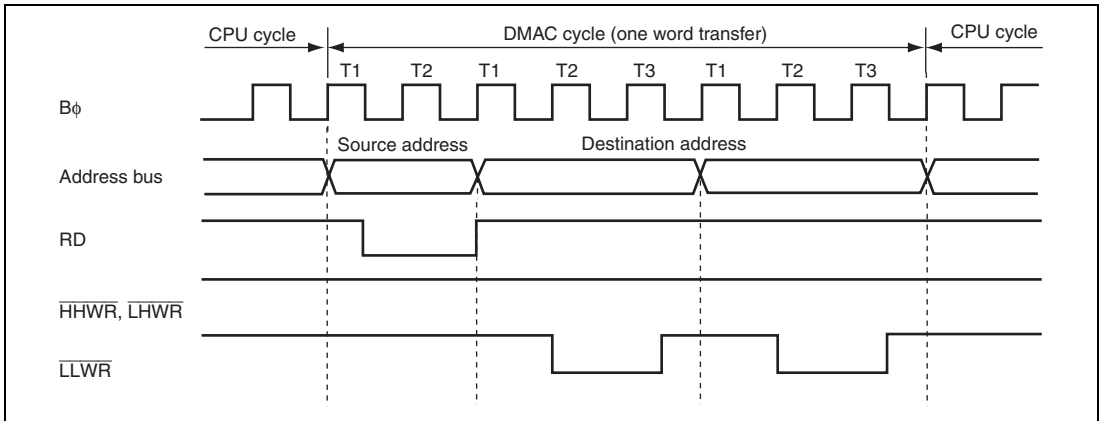

Figure 7.22 shows a transfer example when multiple transfer requests from channels 0 to 2.

**Figure 7.22 Example of Timing for Channel Priority**

### 7.4.9 DMA Basic Bus Cycle

Figure 7.23 shows an examples of signal timing of a basic bus cycle. In figure 7.23, data is transferred in words from the 16-bit 2-state access space to the 8-bit 3-state access space. When the bus mastership is passed from the DMAC to the CPU, data is read from the source address and it is written to the destination address. The bus is not released between the read and write cycles by other bus requests. DMAC bus cycles follows the bus controller settings.

**Figure 7.23 Example of Bus Timing of DMA Transfer**

### 7.4.10 Bus Cycles in Dual Address Mode

#### (1) Normal Transfer Mode (Cycle Stealing Mode)

In cycle stealing mode, the bus is released every time one transfer size of data (one byte, one word, or one longword) is completed. One bus cycle or more by the CPU are executed in the bus released cycles.

In figure 7.24, the  $\overline{\text{TEND}}$  signal output is enabled and data is transferred in words from the external 16-bit 2-state access space to the external 16-bit 2-state access space in normal transfer mode by cycle stealing.

**Figure 7.24 Example of Transfer in Normal Transfer Mode by Cycle Stealing**

In figures 7.25 and 7.26, the  $\overline{\text{TEND}}$  signal output is enabled and data is transferred in longwords from the external 16-bit 2-state access space to the external 16-bit 2-state access space in normal transfer mode by cycle stealing.

In figure 7.25, the transfer source (DSAR) is not aligned with a longword boundary and the transfer destination (DDAR) is aligned with a longword boundary.

In figure 7.26, the transfer source (DSAR) is aligned with a longword boundary and the transfer destination (DDAR) is not aligned with a longword boundary.

**Figure 7.25 Example of Transfer in Normal Transfer Mode by Cycle Stealing (Transfer Source DSAR = Odd Address and Source Address Increment)**

**Figure 7.26 Example of Transfer in Normal Transfer Mode by Cycle Stealing (Transfer Destination DDAR = Odd Address and Destination Address Decrement)**

## (2) Normal Transfer Mode (Burst Mode)

In burst mode, one byte, one word, or one longword of data continues to be transferred until the transfer end condition is satisfied.

When a burst transfer starts, a transfer request from a channel having priority is suspended until the burst transfer is completed.

In figure 7.27, the  $\overline{\text{TEND}}$  signal output is enabled and data is transferred in words from the external 16-bit 2-state access space to the external 16-bit 2-state access space in normal transfer mode by burst access.

**Figure 7.27 Example of Transfer in Normal Transfer Mode by Burst Access**

### (3) Block Transfer Mode

In block transfer mode, the bus is released every time a 1-block size of transfers at a single transfer request is completed.

In figure 7.28, the  $\overline{\text{TEND}}$  signal output is enabled and data is transferred in words from the external 16-bit 2-state access space to the external 16-bit 2-state access space in block transfer mode.

**Figure 7.28 Example of Transfer in Block Transfer Mode**

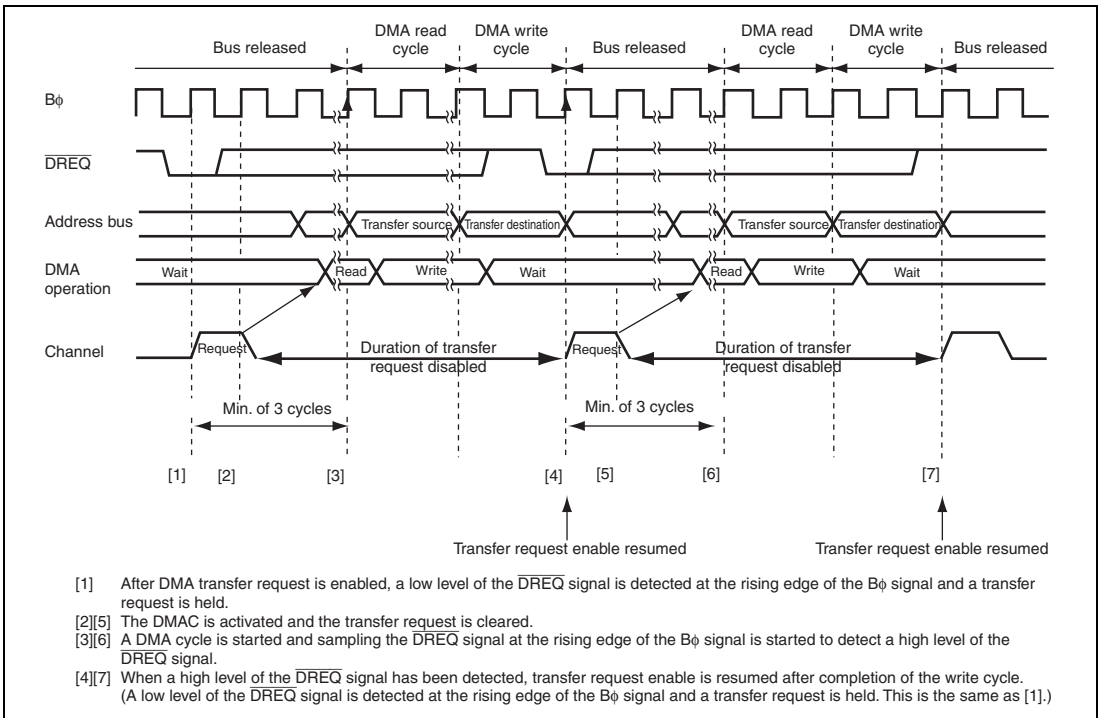

#### (4) Activation Timing by $\overline{\text{DREQ}}$ Falling Edge

Figure 7.29 shows an example of normal transfer mode activated by the  $\overline{\text{DREQ}}$  signal falling edge.

The  $\overline{\text{DREQ}}$  signal is sampled every cycle from the next rising edge of the  $\text{B}\phi$  signal immediately after the DTE bit write cycle.

When a low level of the  $\overline{\text{DREQ}}$  signal is detected while a transfer request by the  $\overline{\text{DREQ}}$  signal is enabled, a transfer request is held in the DMAC. When the DMAC is activated, the transfer request is cleared and starts detecting a high level of the  $\overline{\text{DREQ}}$  signal for falling edge detection. If a high level of the  $\overline{\text{DREQ}}$  signal has been detected until completion of the DMA write cycle, receiving the next transfer request resumes and then a low level of the  $\overline{\text{DREQ}}$  signal is detected. This operation is repeated until the transfer is completed.

**Figure 7.29 Example of Transfer in Normal Transfer Mode Activated by  $\overline{\text{DREQ}}$  Falling Edge**

### (5) Activation Timing by $\overline{\text{DREQ}}$ Low Level

Figure 7.30 shows an example of normal transfer mode activated by the  $\overline{\text{DREQ}}$  signal low level.

The  $\overline{\text{DREQ}}$  signal is sampled every cycle from the next rising edge of the  $\text{B}\phi$  signal immediately after the DTE bit write cycle.

When a low level of the  $\overline{\text{DREQ}}$  signal is detected while a transfer request by the  $\overline{\text{DREQ}}$  signal is enabled, a transfer request is held in the DMAC. When the DMAC is activated, the transfer request is cleared. Receiving the next transfer request resumes after completion of the write cycle and then a low level of the  $\overline{\text{DREQ}}$  signal is detected. This operation is repeated until the transfer is completed.

**Figure 7.30 Example of Transfer in Normal Transfer Mode Activated by  $\overline{\text{DREQ}}$  Low Level**

Figure 7.31 shows an example of block transfer mode activated by the  $\overline{\text{DREQ}}$  signal low level.

The  $\overline{\text{DREQ}}$  signal is sampled every cycle from the next rising edge of the  $\text{B}\phi$  signal immediately after the DTE bit write cycle.

When a low level of the  $\overline{\text{DREQ}}$  signal is detected while a transfer request by the  $\overline{\text{DREQ}}$  signal is enabled, a transfer request is held in the DMAC. When the DMAC is activated, the transfer request is cleared. Receiving the next transfer request resumes after completion of the write cycle and then a low level of the  $\overline{\text{DREQ}}$  signal is detected. This operation is repeated until the transfer is completed.

**Figure 7.31 Example of Transfer in Block Transfer Mode Activated by  $\overline{\text{DREQ}}$  Low Level**

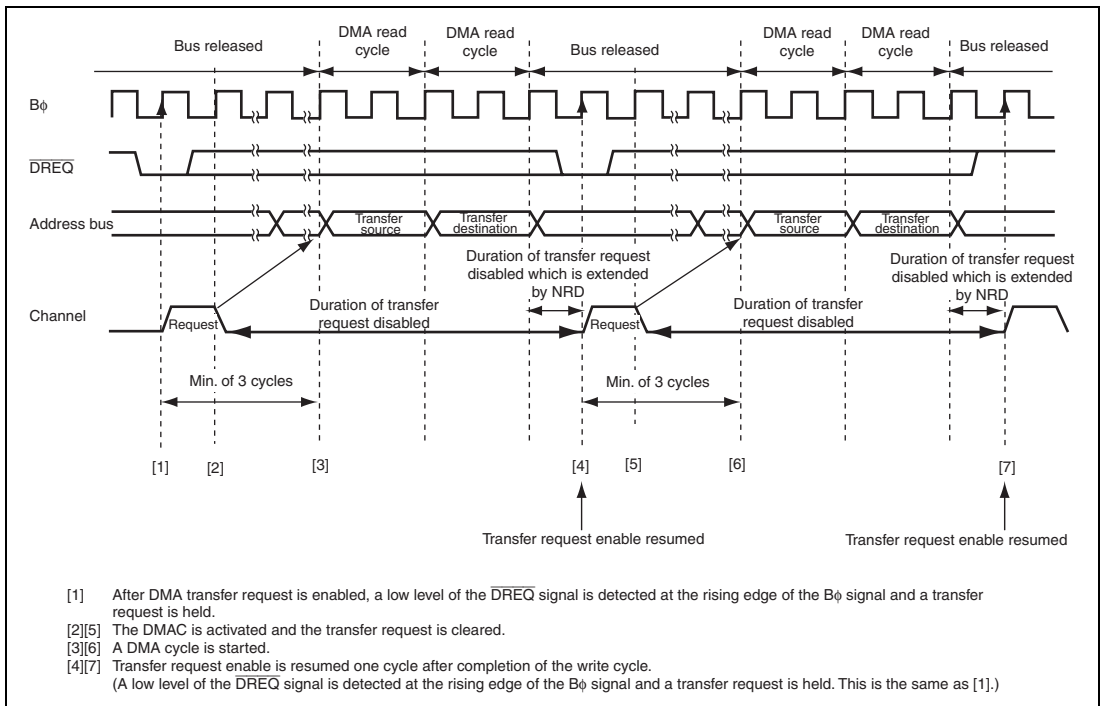

**(6) Activation Timing by  $\overline{\text{DREQ}}$  Low Level with  $\text{NRD} = 1$** 

When the  $\text{NRD}$  bit in  $\text{DMDR}$  is set to 1, the timing of receiving the next transfer request is delayed for one cycle.

Figure 7.32 shows an example of normal transfer mode activated by the  $\overline{\text{DREQ}}$  signal low level with  $\text{NRD} = 1$ .

The  $\overline{\text{DREQ}}$  signal is sampled every cycle from the next rising edge of the  $\text{B}\phi$  signal immediately after the  $\text{DTE}$  bit write cycle.

When a low level of the  $\overline{\text{DREQ}}$  signal is detected while a transfer request by the  $\overline{\text{DREQ}}$  signal is enabled, a transfer request is held in the  $\text{DMAC}$ . When the  $\text{DMAC}$  is activated, the transfer request is cleared. Receiving the next transfer request resumes after completion of the write cycle and then a low level of the  $\overline{\text{DREQ}}$  signal is detected. This operation is repeated until the transfer is completed.

**Figure 7.32 Example of Transfer in Normal Transfer Mode Activated by  $\overline{\text{DREQ}}$  Low Level with  $\text{NRD} = 1$**

### 7.4.11 Bus Cycles in Single Address Mode

#### (1) Single Address Mode (Read and Cycle Stealing)

In single address mode, one byte, one word, or one longword of data is transferred at a single transfer request and after the transfer the bus is released temporarily. One bus cycle or more by the CPU are executed in the bus released cycles.

In figure 7.33, the  $\overline{\text{TEND}}$  signal output is enabled and data is transferred in bytes from the external 8-bit 2-state access space to the external device in single address mode (read).

**Figure 7.33 Example of Transfer in Single Address Mode (Byte Read)**

## (2) Single Address Mode (Write and Cycle Stealing)

In single address mode, data of one byte, one word, or one longword is transferred at a single transfer request and after the transfer the bus is released temporarily. One bus cycle or more by the CPU are executed in the bus released cycles.

In figure 7.34, the  $\overline{\text{TEND}}$  signal output is enabled and data is transferred in bytes from the external 8-bit 2-state access space to the external device in single address mode (write).

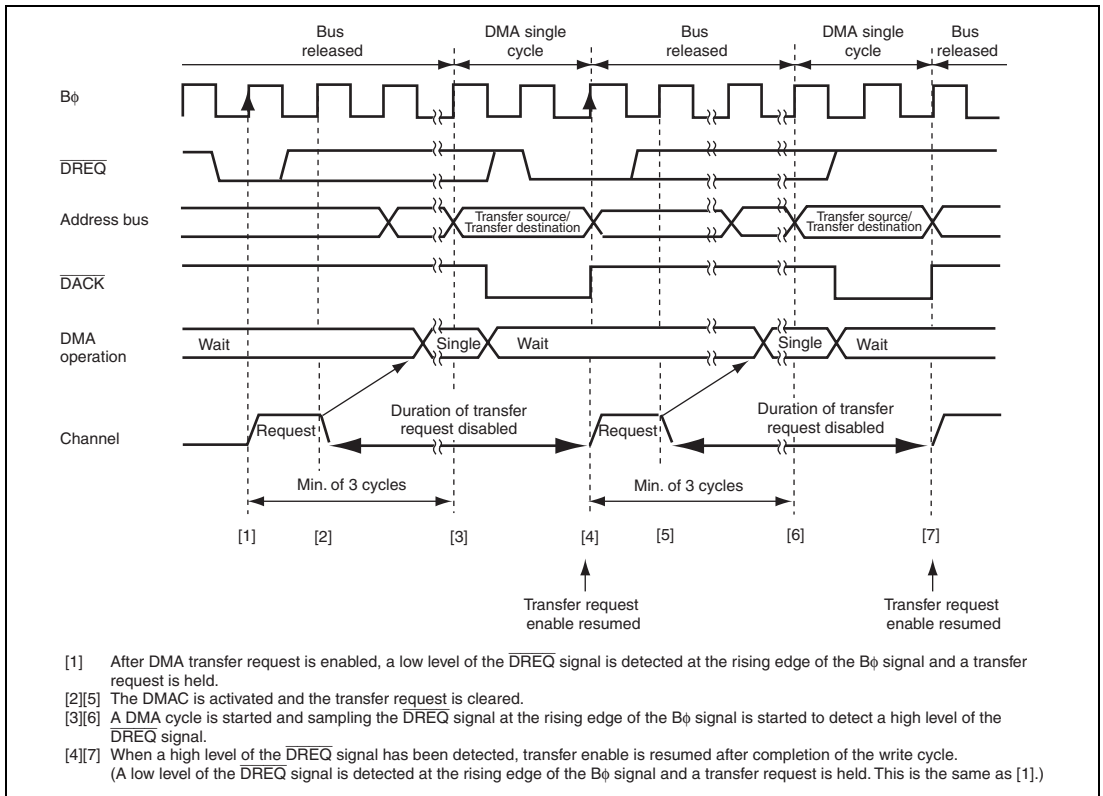

**Figure 7.34 Example of Transfer in Single Address Mode (Byte Write)**

### (3) Activation Timing by $\overline{\text{DREQ}}$ Falling Edge

Figure 7.35 shows an example of single address mode activated by the  $\overline{\text{DREQ}}$  signal falling edge.

The  $\overline{\text{DREQ}}$  signal is sampled every cycle from the next rising edge of the  $\text{B}\phi$  signal immediately after the DTE bit write cycle.

When a low level of the  $\overline{\text{DREQ}}$  signal is detected while a transfer request by the  $\overline{\text{DREQ}}$  signal is enabled, a transfer request is held in the DMAC. When the DMAC is activated, the transfer request is cleared and starts detecting a high level of the  $\overline{\text{DREQ}}$  signal for falling edge detection. If a high level of the  $\overline{\text{DREQ}}$  signal has been detected until completion of the single cycle, receiving the next transfer request resumes and then a low level of the  $\overline{\text{DREQ}}$  signal is detected. This operation is repeated until the transfer is completed.

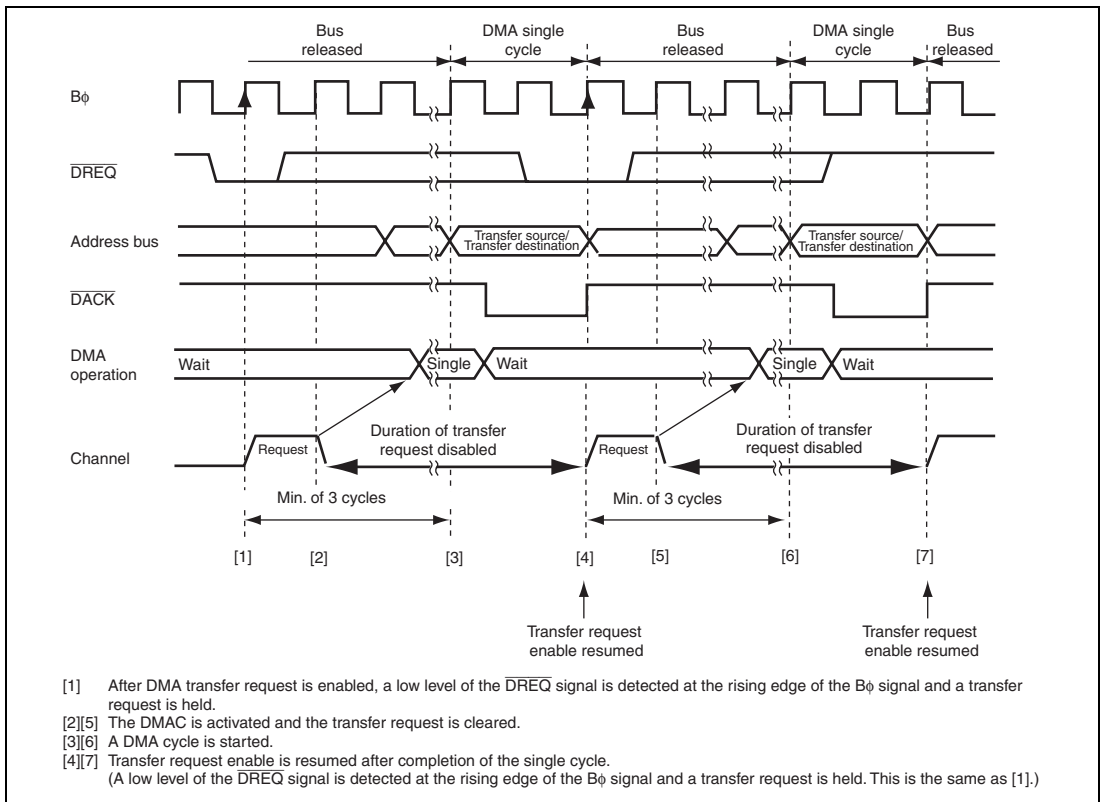

**Figure 7.35 Example of Transfer in Single Address Mode Activated by  $\overline{\text{DREQ}}$  Falling Edge**

#### (4) Activation Timing by $\overline{\text{DREQ}}$ Low Level

Figure 7.36 shows an example of normal transfer mode activated by the  $\overline{\text{DREQ}}$  signal low level.

The  $\overline{\text{DREQ}}$  signal is sampled every cycle from the next rising edge of the  $\text{B}\phi$  signal immediately after the DTE bit write cycle.

When a low level of the  $\overline{\text{DREQ}}$  signal is detected while a transfer request by the  $\overline{\text{DREQ}}$  signal is enabled, a transfer request is held in the DMAC. When the DMAC is activated, the transfer request is cleared. Receiving the next transfer request resumes after completion of the single cycle and then a low level of the  $\overline{\text{DREQ}}$  signal is detected. This operation is repeated until the transfer is completed.

**Figure 7.36 Example of Transfer in Single Address Mode Activated by  $\overline{\text{DREQ}}$  Low Level**

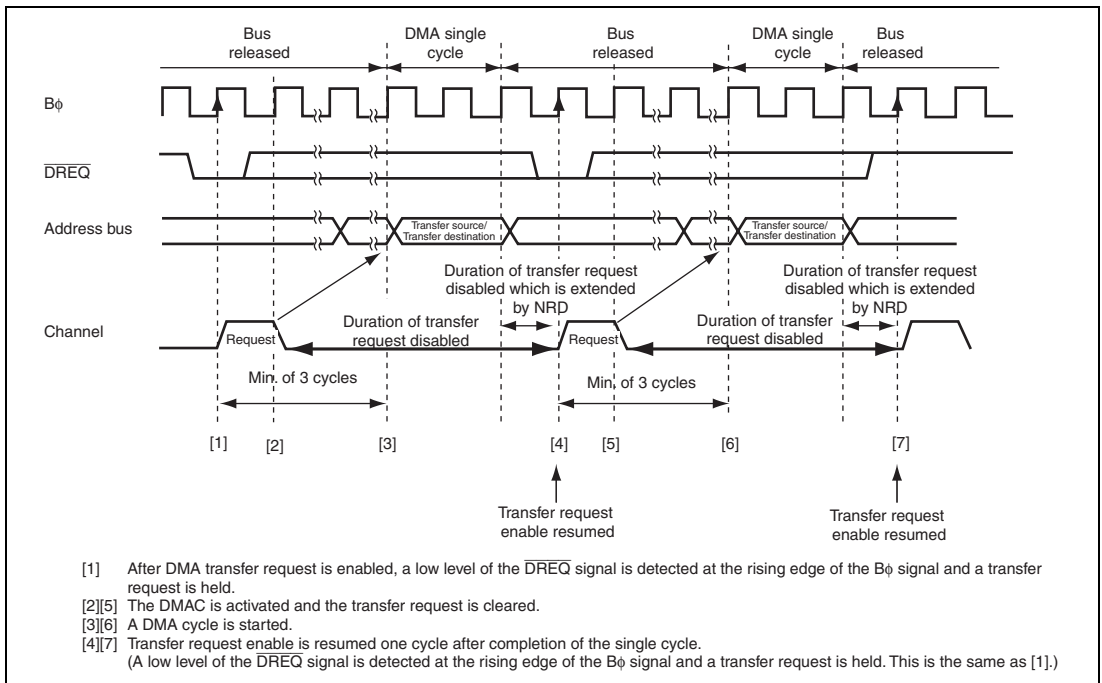

### (5) Activation Timing by $\overline{\text{DREQ}}$ Low Level with $\text{NRD} = 1$

When the NRD bit in DMDR is set to 1, the timing of receiving the next transfer request is delayed for one cycle.

Figure 7.37 shows an example of single address mode activated by the  $\overline{\text{DREQ}}$  signal low level with  $\text{NRD} = 1$ .

The  $\overline{\text{DREQ}}$  signal is sampled every cycle from the next rising edge of the  $\text{B}\phi$  signal immediately after the DTE bit write cycle.

When a low level of the  $\overline{\text{DREQ}}$  signal is detected while a transfer request by the  $\overline{\text{DREQ}}$  signal is enabled, a transfer request is held in the DMAC. When the DMAC is activated, the transfer request is cleared. Receiving the next transfer request resumes after one cycle of the transfer request duration inserted by  $\text{NRD} = 1$  on completion of the single cycle and then a low level of the  $\overline{\text{DREQ}}$  signal is detected. This operation is repeated until the transfer is completed.

**Figure 7.37 Example of Transfer in Single Address Mode Activated by  $\overline{\text{DREQ}}$  Low Level with  $\text{NRD} = 1$**

## 7.5 DMA Transfer End

Operations on completion of a transfer differ according to the transfer end condition. DMA transfer completion is indicated that the DTE and ACT bits in DMDR are changed from 1 to 0.

### (1) Transfer End by DTCR Change from 1, 2, or 4, to 0

When DTCR is changed from 1, 2, or 4 to 0, a DMA transfer for the channel is completed. The DTE bit in DMDR is cleared to 0 and the DTIF bit in DMDR is set to 1. At this time, when the DTIE bit in DMDR is set to 1, a transfer end interrupt by the transfer counter is requested. When the DTCR value is 0 before the transfer, the transfer is not stopped.

### (2) Transfer End by Transfer Size Error Interrupt

When the following conditions are satisfied while the TSEIE bit in DMDR is set to 1, a transfer size error occurs and a DMA transfer is terminated. At this time, the DTE bit in DMR is cleared to 0 and the ESIF bit in DMDR is set to 1.

- In normal transfer mode and repeat transfer mode, when the next transfer is requested while a transfer is disabled due to the DTCR value less than the data access size
- In block transfer mode, when the next transfer is requested while a transfer is disabled due to the DTCR value less than the block size

When the TSEIE bit in DMDR is cleared to 0, data is transferred until the DTCR value reaches 0. A transfer size error is not generated. Operation in each transfer mode is shown below.

- In normal transfer mode and repeat transfer mode, when the DTCR value is less than the data access size, data is transferred in bytes
- In block transfer mode, when the DTCR value is less than the block size, the specified size of data in DTCR is transferred instead of transferring the block size of data. The transfer is performed in bytes.

### (3) Transfer End by Repeat Size End Interrupt

In repeat transfer mode, when the next transfer is requested after completion of a 1-repeat size data transfer while the RPTIE bit in DACR is set to 1, a repeat size end interrupt is requested. When the interrupt is requested to complete DMA transfer, the DTE bit in DMDR is cleared to 0 and the ESIF bit in DMDR is set to 1. Under this condition, setting the DTE bit to 1 resumes the transfer.

In block transfer mode, when the next transfer is requested after completion of a 1-block size data transfer, a repeat size end interrupt can be requested.

#### **(4) Transfer End by Interrupt on Extended Repeat Area Overflow**

When an overflow on the extended repeat area occurs while the extended repeat area is specified and the SARIE or DARIE bit in DACR is set to 1, an interrupt by an extended repeat area overflow is requested. When the interrupt is requested, the DMA transfer is terminated, the DTE bit in DMDR is cleared to 0, and the ESIF bit in DMDR is set to 1.

In dual address mode, even if an interrupt by an extended repeat area overflow occurs during a read cycle, the following write cycle is performed.

In block transfer mode, even if an interrupt by an extended repeat area overflow occurs during a 1-block transfer, the remaining data is transferred. The transfer is not terminated by an extended repeat area overflow interrupt unless the current transfer is complete.

#### **(5) Transfer End by Clearing DTE Bit in DMDR**

When the DTE bit in DMDR is cleared to 0 by the CPU, a transfer is completed after the current DMA cycle and a DMA cycle in which the transfer request is accepted are completed.

In block transfer mode, a DMA transfer is completed after 1-block data is transferred.

#### **(6) Transfer End by NMI Interrupt**

When an NMI interrupt is requested, the DTE bits for all the channels are cleared to 0 and the ERRF bit in DMDR\_0 is set to 1. When an NMI interrupt is requested during a DMA transfer, the transfer is forced to stop. To perform DMA transfer after an NMI interrupt is requested, clear the ERRF bit to 0 and then set the DTE bits for the channels to 1.

The transfer end timings after an NMI interrupt is requested are shown below.

##### **(a) Normal Transfer Mode and Repeat Transfer Mode**

In dual address mode, a DMA transfer is completed after completion of the write cycle for one transfer unit.

In single address mode, a DMA transfer is completed after completion of the bus cycle for one transfer unit.

##### **(b) Block Transfer Mode**

A DMA transfer is forced to stop. Since a 1-block size of transfers is not completed, operation is not guaranteed.

In dual address mode, the write cycle corresponding to the read cycle is performed. This is similar to (a) in normal transfer mode.

## **(7) Transfer End by Address Error**

When an address error occurs, the DTE bits for all the channels are cleared to 0 and the ERRF bit in DMDR\_0 is set to 1. When an address error occurs during a DMA transfer, the transfer is forced to stop. To perform a DMA transfer after an address error occurs, clear the ERRF bit to 0 and then set the DTE bits for the channels.

The transfer end timing after an address error is the same as that after an NMI interrupt.

## **(8) Transfer End by Hardware Standby Mode or Reset**

The DMAC is initialized by a reset and a transition to the hardware standby mode. A DMA transfer is not guaranteed.

# **7.6 Relationship among DMAC and Other Bus Masters**

## **7.6.1 CPU Priority Control Function Over DMAC**

The CPU priority control function over DMAC can be used according to the CPU priority control register (CPUPCR) setting. For details, see section 5.7, CPU Priority Control Function Over DMAC.

The priority level of the DMAC is specified by bits DMAP2 to DMAP0 and can be specified for each channel.

The priority level of the CPU is specified by bits CPUP2 to CPUP0. The value of bits CPUP2 to CPUP0 is updated according to the exception handling priority.

If the CPU priority control is enabled by the CPUPCE bit in CPUPCR, when the CPU has priority over the DMAC, a transfer request for the corresponding channel is masked and the transfer is not activated. When another channel has priority over or the same as the CPU, a transfer request is received regardless of the priority between channels and the transfer is activated.

If the priority level of the transfer request masked by the CPU priority control function is changed or the CPU priority is changed, the transfer request may be received and the transfer is started.

When the CPUPCE bit is cleared to 0, it is regarded as the lowest priority. Transfer requests masked are suspended. If a transfer request is suspended, it is cleared by clearing the DTE bit to 0.

## 7.6.2 Bus Arbitration among DMAC and Other Bus Masters

When DMA transfer cycles are consecutively performed, bus cycles of other bus masters may be inserted between the transfer cycles. The DMAC can release the bus temporarily to pass the bus to other bus masters.

The consecutive DMA transfer cycles may not be divided according to the transfer mode settings to achieve high-speed access.

The read and write cycles of a DMA transfer are not separated. Refreshing, external bus release, and on-chip bus master (CPU) cycles are not inserted between the read and write cycles of a DMA transfer.

In block transfer mode and an auto request transfer by burst access, bus cycles of the DMA transfer are consecutively performed. For this duration, since the DMAC has priority over the CPU, accesses to the external space is suspended (the IBCCS bit in the bus control register 2 (BCR2) is cleared to 0).

When the bus is passed to another channel or an auto request transfer by cycle stealing, bus cycles of the DMAC and on-chip bus master are performed alternatively.

When the arbitration function among the DMAC and on-chip bus masters is enabled by setting the IBCCS bit in BCR2, the bus is used alternatively except the bus cycles which are not separated. For details, see section 6, Bus Controller (BSC).

A conflict may occur between external space access of the DMAC and a refresh cycle or an external bus release cycle. Even if a burst or block transfer is performed by the DMAC, the transfer is stopped temporarily and a cycle of refresh or external bus release is inserted by the BSC (when the CPU external access does not have priority over a DMAC transfer, the transfer is not operated until the DMAC releases the bus).

In dual address mode, the DMAC releases the external bus after the external space write cycle. Since the read and write cycles are not separated, the bus is not released.

An internal space (on-chip memory and internal I/O registers) access of the DMAC and an external bus release cycle may be performed at the same time.

Each interrupt source is specified by the interrupt enable bit in the register for the corresponding channel. A transfer end interrupt by the transfer counter, a transfer size error interrupt, a repeat size end interrupt, an interrupt by an extended repeat area overflow on the source address, and an interrupt by an extended repeat area overflow on the destination address are enabled or disabled by the DTIE bit in DMDR, the TSEIE bit in DMDR, the RPTIE bit in DACR, SARIE bit in DACR, and the DARIE bit in DACR, respectively.

A transfer end interrupt by the transfer counter is generated when the DTIF bit in DMDR is set to 1. The DTIF bit is set to 1 when DTCR becomes 0 by a transfer while the DTIE bit in DMDR is set to 1.

An interrupt other than the transfer end interrupt by the transfer counter is generated when the ESIF bit in DMDR is set to 1. The ESIF bit is set to 1 when the conditions are satisfied by a transfer while the enable bit is set to 1.

A transfer size error interrupt is generated when the next transfer cannot be performed because the DTCR value is less than the data access size, meaning that the data access size of transfers cannot be performed. In block transfer mode, the block size is compared with the DTCR value for transfer error decision.

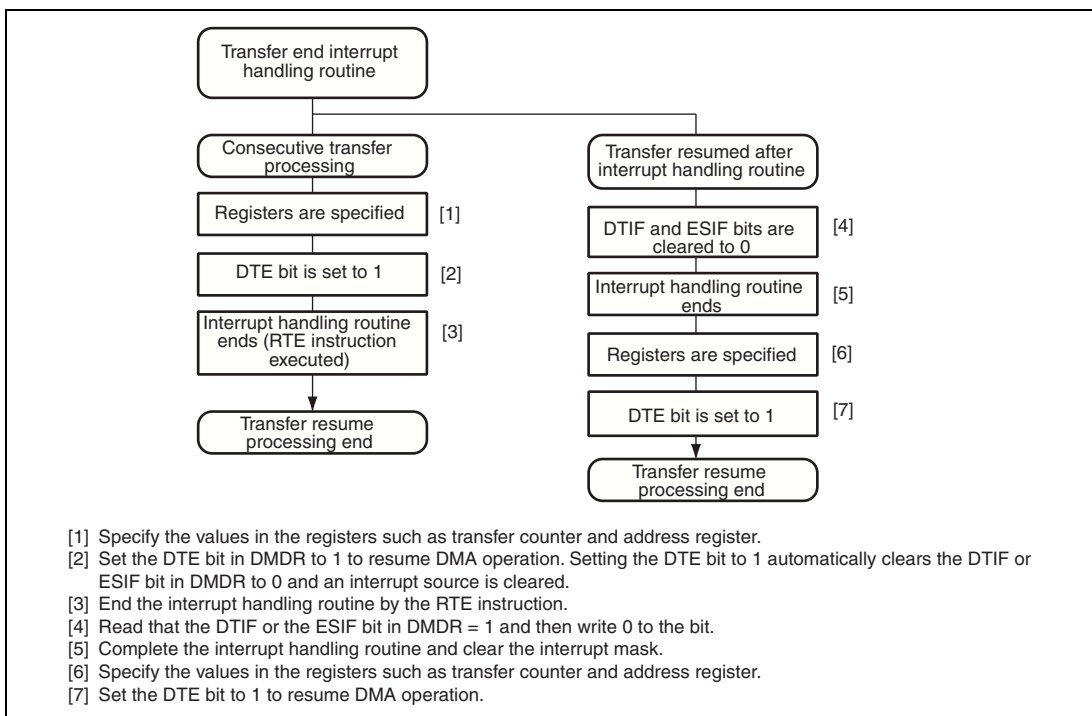

A repeat size end interrupt is generated when the next transfer is requested after completion of the repeat size of transfers in repeat transfer mode. Even when the repeat area is not specified in the address register, the transfer can be stopped periodically according to the repeat size. At this time, when a transfer end interrupt by the transfer counter is generated, the ESIF bit is set to 1.

An interrupt by an extended repeat area overflow on the source and destination addresses is generated when the address exceeds the extended repeat area (overflow). At this time, when a transfer end interrupt by the transfer counter, the ESIF bit is set to 1.

Figure 7.38 is a block diagram of interrupts and interrupt flags. To clear an interrupt, clear the DTIF or ESIF bit in DMDR to 0 in the interrupt handling routine or continue the transfer by setting the DTE bit in DMDR after setting the register. Figure 7.39 shows procedure to resume the transfer by clearing a interrupt.

**Figure 7.38** Interrupt and Interrupt Sources

**Figure 7.39** Procedure Example of Resuming Transfer by Clearing Interrupt Source

## 7.8 Notes on Usage

### 1. DMAC Register Access During Operation

Except for clearing the DTE bit in DMDR, the settings for channels being transferred (including waiting state) must not be changed. The register settings must be changed during the transfer prohibited state.

### 2. Settings of Module Stop Function

The DMAC operation can be enabled or disabled by the module stop control register. The DMAC is enabled by the initial value.

Setting bit MSTPA13 in MSTPCRA stops the clock supplied to the DMAC and the DMAC enters the module stop state. However, when a transfer for a channel is enabled or when an interrupt is being requested, bit MSTPA13 cannot be set to 1. Clear the DTE bit to 0, clear the DTIF or DTIE bit in DMDR to 0, and then set bit MSTPA13.

When the clock is stopped, the DMAC registers cannot be accessed. However, the following register settings are valid in the module stop state. Disable them before entering the module stop state, if necessary.

— TENDE bit in DMDR is 1 (the TEND signal output enabled)

— DACKE bit in DMDR is 1 (the DACK signal output enabled)

### 3. Activation by $\overline{\text{DREQ}}$ Falling Edge

The  $\overline{\text{DREQ}}$  falling edge detection is synchronized with the DMAC internal operation.

A. Activation request waiting state: Waiting for detecting the  $\overline{\text{DREQ}}$  low level. A transition to 2. is made.

B. Transfer waiting state: Waiting for a DMAC transfer. A transition to 3. is made.

C. Transfer prohibited state: Waiting for detecting the  $\overline{\text{DREQ}}$  high level. A transition to 1. is made.

After a DMAC transfer enabled, a transition to 1. is made. Therefore, the  $\overline{\text{DREQ}}$  signal is sampled by low level detection at the first activation after a DMAC transfer enabled.

### 4. Acceptation of Activation Source

At the beginning of an activation source reception, a low level is detected regardless of the setting of  $\overline{\text{DREQ}}$  falling edge or low level detection. Therefore, if the  $\overline{\text{DREQ}}$  signal is driven low before setting DMDR, the low level is received as a transfer request.

When the DMAC is activated, clear the  $\overline{\text{DREQ}}$  signal of the previous transfer.

## Section 8 I/O Ports

Table 8.1 summarizes the port functions. The pins of each port also have other functions such as input/output pins of on-chip peripheral modules or external interrupt input pins. Each I/O port includes a data direction register (DDR) that controls input/output, a data register (DR) that stores output data, a port register (PORT) used to read the pin states, and an input buffer control register (ICR) that controls input buffer on/off. Ports 4 and 5 do not have a DR or a DDR register.

Ports D, H, J and K have internal input pull-up MOSs and a pull-up MOS control register (PCR) that controls the on/off state of the input pull-up MOSs.

Port 2 includes an open-drain control register (ODR) that controls on/off of the output buffer PMOSs.

Ports 1, 2, 3, 6, A, D, H, J, and K can drive a single TTL load and capacitive loads up to 30 pF.

All of the I/O ports can drive Darlington transistors when functioning as output ports.

Schmitt-trigger inputs are enabled when a port is used as the  $\overline{\text{IRQ}}$  and TPU inputs.

**Table 8.1 Port Functions**

Port	Description	Bit	Function			Schmitt-Trigger Input*1	Input Pull-up MOS Function	Open-Drain Output Function

- Notes: 1. Pins without Schmitt-trigger input buffer have CMOS input buffer.  
2. Supported only by the H8SX/1527R.

## 8.1 Register Descriptions

Table 8.2 lists each port registers.

**Table 8.2 Register Configuration in Each Port**

Port	Number of Pins	Registers						
		DDR	DR	PORT	ICR	PCR	ODR	PHRTIDR
Port 1	8	O	O	O	O	—	—	—
Port 2 <sup>*1</sup>	4	O	O	O	O	—	O	—
Port 3	8	O	O	O	O	—	—	—
Port 4	8	—	—	O	O	—	—	—
Port 5	8	—	—	O	O	—	—	—
Port 6 <sup>*2</sup>	7	O	O	O	O	—	—	—
Port A <sup>*3</sup>	7	O	O	O	O	—	—	—
Port D	8	O	O	O	O	O	—	—
Port H	8	O	O	O	O	O	—	O
Port J	8	O	O	O	O	O	—	—
Port K	8	O	O	O	O	O	—	—

[Legend]

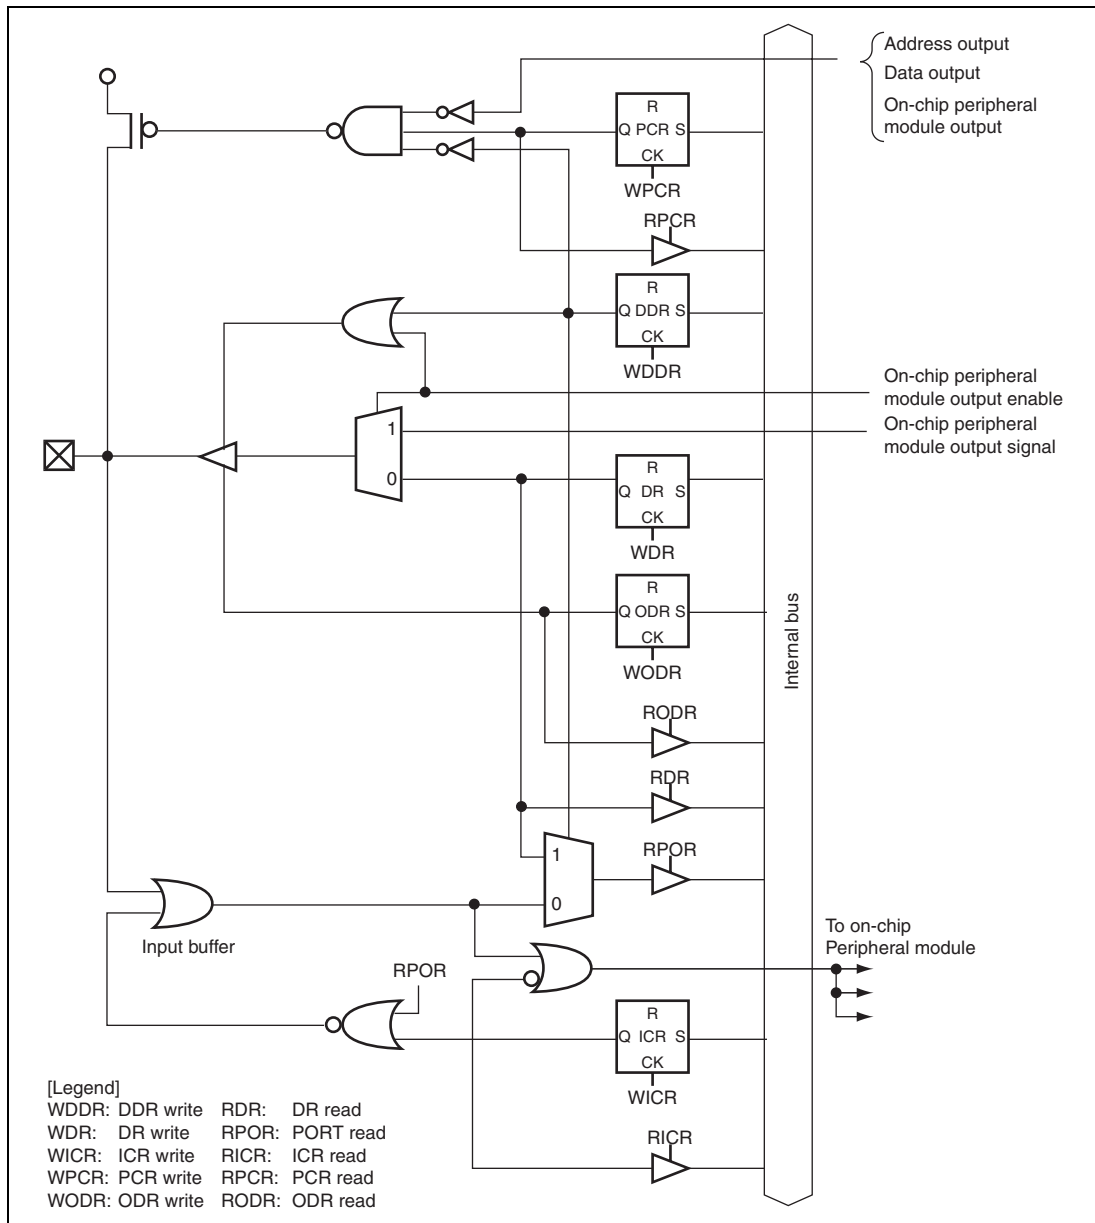

O: Register exists

—: No register exists

- Notes:
1. The lower four bits are valid and the upper four bits are reserved. The write value should always be the initial value.
  2. The lower seven bits are valid and the upper one bit is reserved. The write value should always be the initial value.
  3. The upper seven bits are valid and the lower one bit is reserved. The write value should always be the initial value.

Figure 8.1 is a port block diagram.

**Figure 8.1 Port Block Diagram**

### 8.1.1 Data Direction Register (PnDDR) (n = 1 to 3, 6, A, D, H, J, and K)

DDR is an 8-bit write-only register that specifies the port input or output for each bit. A read from the DDR is invalid and DDR is always read as an undefined value.

When the general I/O port function is selected, the corresponding pin functions as an output port by setting the corresponding DDR bit to 1; the corresponding pin functions as an input port by clearing the corresponding DDR bit to 0.

Bit	7	6	5	4	3	2	1	0
Bit Name	Pn7DDR	Pn6DDR	Pn5DDR	Pn4DDR	Pn3DDR	Pn2DDR	Pn1DDR	Pn0DDR
Initial Value	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

Note: The lower four bits are valid and the upper four bits are reserved for port 2 data direction register (P2DDR).  
The lower seven bits are valid and the upper one bit is reserved for port 6 data direction register (P6DDR).  
The upper seven bits are valid and the lower one bit is reserved for port A data direction register (PADDR).

### 8.1.2 Data Register (PnDR) (n = 1 to 3, 6, A, D, H, J, and K)

DR is an 8-bit readable/writable register that stores the output data of the pins to be used as the general output port.

The initial value of DR is H'00.

Bit	7	6	5	4	3	2	1	0
Bit Name	Pn7DR	Pn6DR	Pn5DR	Pn4DR	Pn3DR	Pn2DR	Pn1DR	Pn0DR
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: The lower four bits are valid and the upper four bits are reserved for port 2 data register (P2DR).  
The lower seven bits are valid and the upper one bit is reserved for port 6 data register (P6DR).  
The upper seven bits are valid and the lower one bit is reserved for port A data register (PADR).

### 8.1.3 Port Register (PORTn) (n = 1 to 6, A, D, H, J, and K)

PORT is an 8-bit read-only register that reflects the port pin status. A write to PORT is invalid. When PORT is read, the DR bits that correspond to the respective DDR bits set to 1 are read and the status of each pin whose corresponding DDR bit is cleared to 0 is also read regardless of the ICR value.

The initial value of PORT is undefined and is determined based on the port pin status.

Bit	7	6	5	4	3	2	1	0
Bit Name	Pn7	Pn6	Pn5	Pn4	Pn3	Pn2	Pn1	Pn0
Initial Value	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined
R/W	R	R	R	R	R	R	R	R

Note: The lower four bits are valid and the upper four bits are reserved for port 2 register (PORT2).  
 The lower seven bits are valid and the upper one bit is reserved for port 6 register (PORT6).  
 The upper seven bits are valid and the lower one bit is reserved for port A register (PORTA).

### 8.1.4 Input Buffer Control Register (PnICR) (n = 1 to 6, A, D, H, J, and K)

ICR is an 8-bit readable/writable register that controls the port input buffers.

For bits in ICR set to 1, the input buffers of the corresponding pins are valid. For bits in ICR cleared to 0, the input buffers of the corresponding pins are invalid and the input signals are fixed high.

When the pin functions as an input for the peripheral modules, the corresponding bits should be set to 1. The initial value should be written to a bit whose corresponding pin is not used as an input or is used as an analog input/output pin.

When PORT is read, the pin status is always read regardless of the ICR value. On-chip modules are not affected by the pin status when the ICR value is cleared to 0.

If ICR is modified, an internal edge may occur depending on the pin status. Accordingly, ICR should be modified when the corresponding input pins are not used. For example, in  $\overline{\text{IRQ}}$  input, modify ICR while the corresponding interrupt is disabled, clear the IRQF flag in ISR of the interrupt controller to 0, and then enable the corresponding interrupt. If an edge occurs after the ICR setting, the edge should be cancelled.

The initial value of ICR is H'00.

Bit	7	6	5	4	3	2	1	0
Bit Name	Pn7ICR	Pn6ICR	Pn5ICR	Pn4ICR	Pn3ICR	Pn2ICR	Pn1ICR	Pn0ICR
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: The lower four bits are valid and the upper four bits are reserved for port 2 input buffer control register (P2ICR).  
The lower seven bits are valid and the upper one bit is reserved for port 6 input buffer control register (P6ICR).  
The upper seven bits are valid and the lower one bit is reserved for port A input buffer control register (PAICR).

### 8.1.5 Pull-Up MOS Control Register (PnPCR) (n = D, H, J, and K)

PCR is an 8-bit readable/writable register that controls on/off of the port input pull-up MOS.

If a bit in PCR is set to 1 while the pin is in input state, the input pull-up MOS corresponding to the bit in PCR is turned on. Table 8.3 shows the input pull-up MOS status.

The initial value of PCR is H'00.

Bit	7	6	5	4	3	2	1	0
Bit Name	Pn7PCR	Pn6PCR	Pn5PCR	Pn4PCR	Pn3PCR	Pn2PCR	Pn1PCR	Pn0PCR
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

**Table 8.3 Input Pull-Up MOS State**

Port	Pin State	Reset	Software Standby Mode	Other Operation
Port D	On-chip peripheral module output	OFF	OFF	OFF
	Port input	OFF	OFF	ON/OFF
Port H	Port output	OFF	OFF	OFF
	Port input	OFF	OFF	ON/OFF
Port J	On-chip peripheral module output	OFF	OFF	OFF
	Port input	OFF	OFF	ON/OFF
Port K	On-chip peripheral module output	OFF	OFF	OFF
	Port input	OFF	OFF	ON/OFF

[Legend]

OFF: The input pull-up MOS is always off.

ON/OFF: If PCR is set to 1, the input pull-up MOS is on; if PCR is cleared to 0, the input pull-up MOS is off.

### 8.1.6 Open-Drain Control Register (PnODR) (n = 2)

ODR is an 8-bit readable/writable register that selects the open-drain output function.

If a bit in ODR is set to 1, the pin corresponding to that bit in ODR functions as an NMOS open-drain output. If a bit in ODR is cleared to 0, the pin corresponding to that bit in ODR functions as a CMOS output.

The initial value of ODR is H'00.

Bit	7	6	5	4	3	2	1	0
Bit Name	Pn7ODR	Pn6ODR	Pn5ODR	Pn4ODR	Pn3ODR	Pn2ODR	Pn1ODR	Pn0ODR
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: The lower four bits are valid and the upper four bits are reserved for port 2 open drain control register (P2ODR).

### 8.1.7 Port H Realtime Input Data Register (PHRTIDR)

PHRTIDR stores the status of port H using pin  $\overline{\text{IRQ14}}$  as a trigger. The detection method is specified by the IRQ14SR and IRQ14SF bits in the IRQ sense control register H (ISCRH) and is selected from a low level, a falling edge, a rising edge of pin, and both edges of pin  $\overline{\text{IRQ14}}$ . For details, see section 5.3.5, IRQ Sense Control Registers H and L (ISCRH and ISCL).

Bit	7	6	5	4	3	2	1	0
Bit Name	PHRTIDR7	PHRTIDR6	PHRTIDR5	PHRTIDR4	PHRTIDR3	PHRTIDR2	PHRTIDR1	PHRTIDR0
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

## 8.2 Output Buffer Control

This section describes the output priority of each pin.

The name of each peripheral module pin is followed by "\_OE". This (for example: MIOCA4\_OE) indicates whether the output of the corresponding function is valid (1) or if another setting is specified (0). Table 8.4 lists each port output signal's valid setting. For details on the corresponding output signals, see the register description of each peripheral module. If the name of each peripheral module pin is followed by A or B, the pin function can be modified by the port function control register (PFCR). For details, see section 8.3.3, Port Function Control Register B (PFCRB).

### 8.2.1 Port 1

#### (1) P17/ADTRG1/IRQ7

The pin function is switched as shown below according to the P17DDR bit setting.

Module Name	Pin Function	Setting
		I/O Port
		P17DDR
I/O port	P17 output	1
	P17 input (initial setting)	0

#### (2) P16/SCK3/ $\overline{\text{IRQ6}}$

The pin function is switched as shown below according to the combination of the SCI\_3 and P16DDR bit settings.

Module Name	Pin Function	Setting	
		SCI_3	I/O Port
		SCK3_OE	P16DDR
SCI_3	SCK3 output	1	—
I/O port	P16 output	0	1
	P16 input (initial setting)	0	0

**(3) P15/RxD3/ $\overline{\text{IRQ5}}$** 

The pin function is switched as shown below according to the P15DDR bit setting.

Module Name	Pin Function	Setting	
		I/O Port	P15DDR
I/O port	P15 output	1	
	P15 input (initial setting)	0	

**(4) P14/TxD3/ $\overline{\text{IRQ4}}$** 

The pin function is switched as shown below according to the combination of the SCI\_3 and P14DDR bit settings.

Module Name	Pin Function	Setting	
		SCI_4	I/O Port
		TxD3_OE	P14DDR
SCI_3	TxD3 output	1	—
I/O port	P14 output	0	1
	P14 input (initial setting)	0	0

**(5) P13/ADTRG0/ $\overline{\text{IRQ3}}$** 

The pin function is switched as shown below according to the P13DDR bit setting.

Module Name	Pin Function	Setting	
		I/O Port	P13DDR
I/O port	P13 output	1	
	P13 input (initial setting)	0	

**(6) P12/ $\overline{\text{IRQ2}}$** 

The pin function is switched as shown below according to the P12DDR bit setting.

Module Name	Pin Function	Setting
		I/O Port
		P12DDR
I/O port	P12 output	1
	P12 input (initial setting)	0

**(7) P11/ $\overline{\text{IRQ1}}$** 

The pin function is switched as shown below according to the P11DDR bit setting.

Module Name	Pin Function	Setting
		I/O Port
		P11DDR
I/O port	P11 output	1
	P11 input (initial setting)	0

**(8) P10/ $\overline{\text{IRQ0}}$** 

The pin function is switched as shown below according to the P10DDR bit setting.

Module Name	Pin Function	Setting
		I/O Port
		P10DDR
I/O port	P10 output	1
	P10 input (initial setting)	0

## 8.2.2 Port 2

### (1) P23/TIOCC3/TIOCD3/ $\overline{\text{IRQ11}}$ -A

The pin function is switched as shown below according to the combination of the port function control register 9 (PFCR9), TPU\_3, and P23DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_3*	I/O Port
		TIOCD3_OE	P23DDR
TPU_3*	TIOCD3 output	1	—
I/O port	P23 output	0	1
	P23 input (initial setting)	0	0

Note: \* Supported only by the H8SX/1527R.

### (2) P22/TIOCC3/ $\overline{\text{IRQ10}}$ -A

The pin function is switched as shown below according to the combination of the port function control register 9 (PFCR9), TPU\_3, and P22DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_3*	I/O Port
		TIOCD3_OE	P22DDR
TPU_3*	TIOCC3 output	1	—
I/O port	P22 output	0	1
	P22 input (initial setting)	0	0

Note: \* Supported only by the H8SX/1527R.

**(3) P21/TIOCA3/ $\overline{\text{IRQ9-A}}$ / $\overline{\text{SCS2}}$** 

The pin function is switched as shown below according to the combination of the port function control register 9 (PFCR9), SSU\_2, TPU\_3, and P21DDR bit settings.

Module Name	Pin Function	Setting		
		SSU_2	TPU_3*	I/O Port
		$\overline{\text{SCS2\_OE}}$	TIOCA3_OE	P21DDR
SSU_2	$\overline{\text{SCS2}}$ output	1	—	—
TPU_3*	TIOCA3 output	0	1	—
I/O port	P21 output	0	0	1
	P21 input (initial setting)	0	0	0

Note: \* Supported only by the H8SX/1527R.

**(4) P20/TIOCA3/TIOCB3/ $\overline{\text{IRQ8-A}}$** 

The pin function is switched as shown below according to the combination of the port function control register 9 (PFCR9), TPU\_3, and P20DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_3*	I/O Port
		TIOCB3_OE	P20DDR
TPU_3*	TIOCB3 output	1	—
I/O port	P20 output	0	1
	P20 input (initial setting)	0	0

Note: \* Supported only by the H8SX/1527R.

### 8.2.3 Port 3

#### (1) P37/PO15/TIOCA2/TIOCB2/TCLKD

The pin function is switched as shown below according to the combination of the port function control register 9 (PFCR9), TPU\_2, PPG, and P37DDR bit settings.

Module Name	Pin Function	Setting		
		TPU_2*	PPG*	I/O Port
		TIOCB2_OE	PO15_OE	P37DDR
TPU_2*	TIOCB2 output	1	—	—
PPG*	PO15 output	0	1	—
I/O port	P37 output	0	0	1
	P37 input (initial setting)	0	0	0

Note: \* Supported only by the H8SX/1527R.

#### (2) P36/PO14/TIOCA2

The pin function is switched as shown below according to the combination of the port function control register 9 (PFCR9), TPU\_2, PPG, and P36DDR bit settings.

Module Name	Pin Function	Setting		
		TPU_2*	PPG*	I/O Port
		TIOCA2_OE	PO14_OE	P36DDR
TPU_2*	TIOCA2 output	1	—	—
PPG*	PO14 output	0	1	—
I/O port	P36 output	0	0	1
	P36 input (initial setting)	0	0	0

Note: \* Supported only by the H8SX/1527R.

**(3) P35/PO13/TIOCA1/TIOCB1/TCLKC**

The pin function is switched as shown below according to the combination of the port function control register 9 (PFCR9), TPU\_1, PPG, and P35DDR bit settings.

Module Name	Pin Function	Setting		
		TPU_1*	PPG*	I/O Port
		TIOCB1_OE	PO13_OE	P35DDR
TPU_1*	TIOCB1 output	1	—	—
PPG*	PO13 output	0	1	—
I/O port	P35 output	0	0	1
	P35 input (initial setting)	0	0	0

Note: \* Supported only by the H8SX/1527R.

**(4) P34/PO12/TIOCA1**

The pin function is switched as shown below according to the combination of the port function control register 9 (PFCR9), TPU\_1, PPG, and P34DDR bit settings.

Module Name	Pin Function	Setting		
		TPU_1*	PPG*	I/O Port
		TIOCA1_OE	PO12_OE	P34DDR
TPU_1*	TIOCA1 output	1	—	—
PPG*	PO12 output	0	1	—
I/O port	P34 output	0	0	1
	P34 input (initial setting)	0	0	0

Note: \* Supported only by the H8SX/1527R.

**(5) P33/PO11/TIOCC0/TIOCD0/TCLKB**

The pin function is switched as shown below according to the combination of the port function control register 9 (PFCR9), TPU\_0, PPG, and P33DDR bit settings.

Module Name	Pin Function	Setting		
		TPU_0*	PPG*	I/O Port
		TIOCD0_OE	PO11_OE	P33DDR
TPU_0*	TIOCD0 output	1	—	—
PPG*	PO11 output	0	1	—
I/O port	P33 output	0	0	1
	P33 input (initial setting)	0	0	0

Note: \* Supported only by the H8SX/1527R.

**(6) P32/PO10/TIOCC0/TCLKA:**

The pin function is switched as shown below according to the combination of the port function control register 9 (PFCR9), TPU\_0, PPG, and P32DDR bit settings.

Module Name	Pin Function	Setting		
		TPU_0*	PPG*	I/O Port
		TIOCC0_OE	PO10_OE	P32DDR
TPU_0*	TIOCC0 output	1	—	—
PPG*	PO10 output	0	1	—
I/O port	P32 output	0	0	1
	P32 input (initial setting)	0	0	0

Note: \* Supported only by the H8SX/1527R.

**(7) P31/PO9/TIOCA0/TIOCB0**

The pin function is switched as shown below according to the combination of the port function control register 9 (PFCR9), TPU\_0, PPG, and P31DDR bit settings.

Module Name	Pin Function	Setting		
		TPU_0*	PPG*	I/O Port
		TIOCB0_OE	PO9_OE	P31DDR
TPU_0*	TIOCB0 output	1	—	—
PPG*	PO9 output	0	1	—
I/O port	P31 output	0	0	1
	P31 input (initial setting)	0	0	0

Note: \* Supported only by the H8SX/1527R.

**(8) P30/PO8/TIOCA0**

The pin function is switched as shown below according to the combination of the port function control register 9 (PFCR9), TPU\_0, PPG, and P30DDR bit settings.

Module Name	Pin Function	Setting		
		TPU_0*	PPG*	I/O Port
		TIOCA0_OE	PO8_OE	P30DDR
TPU_0*	TIOCA0 output	1	—	—
PPG*	PO8 output	0	1	—
I/O port	P30 output	0	0	1
	P30 input (initial setting)	0	0	0

Note: \* Supported only by the H8SX/1527R.

## 8.2.4 Port 6

### (1) P66/ $\overline{\text{IRQ14}}$

The pin function is switched as shown below according to the P66DDR bit setting.

Module Name	Pin Function	Setting	
		I/O Port	
		P66DDR	
I/O port	P66 output	1	
	P66 input (initial setting)	0	

### (2) P65/ $\overline{\text{IRQ13}}/\text{CRx}$

The pin function is switched as shown below according to the P65DDR bit setting.

Module Name	Pin Function	Setting	
		I/O Port	
		P65DDR	
I/O port	P65 output	1	
	P65 input (initial setting)	0	

### (3) P64/ $\overline{\text{IRQ12}}/\text{CTx}$

The pin function is switched as shown below according to the combination of the RCAN-ET and P64DDR bit settings.

Module Name	Pin Function	Setting	
		RCAN-ET	I/O Port
		CTx_OE	P64DDR
RCAN-ET	CTx output	1	—
I/O port	P64 output	0	1
	P64 input (initial setting)	0	0

**(4) P63/ $\overline{\text{IRQ11}}$ -B**

The pin function is switched as shown below according to the P63DDR bit setting.

Module Name	Pin Function	Setting
		I/O Port
		P63DDR
I/O port	P63 output	1
	P63 input (initial setting)	0

**(5) P62/SCK4/ $\overline{\text{IRQ10}}$ -B**

The pin function is switched as shown below according to the combination of the SCI\_4 and P62DDR bit settings.

Module Name	Pin Function	Setting	
		SCI_4	I/O Port
		SCK4_OE	P62DDR
SCI_4	SCK4 output	1	—
I/O port	P62 output	0	1
	P62 input (initial setting)	0	0

**(6) P61/RxD4/ $\overline{\text{IRQ9}}$ -B**

The pin function is switched as shown below according to the P61DDR bit setting.

Module Name	Pin Function	Setting
		I/O Port
		P61DDR
I/O port	P61 output	1
	P61 input (initial setting)	0

**(7) P60/TxD4/ $\overline{\text{IRQ8}}$ -B**

The pin function is switched as shown below according to the combination of the SCI\_4 and P60DDR bit settings.

Module Name	Pin Function	Setting	
		SCI_4	I/O Port
		TxD4_OE	P60DDR
SCI_4	TxD4 output	1	—
I/O port	P60 output	0	1
	P60 input (initial setting)	0	0

**8.2.5 Port A****(1) PA7**

The pin function is switched as shown below according to the PA7DDR bit setting.

Module Name	Pin Function	Setting
		I/O Port
		PA7DDR
I/O port	B $\phi$ output	1
	PA7 input (initial setting)	0

**(2) PA6**

The pin function is switched as shown below according to the PA6DDR bit setting.

Module Name	Pin Function	Setting
		I/O Port
		PA6DDR
I/O port	PA6 output	1
	PA6 input (initial setting)	0

**(3) PA5**

The pin function is switched as shown below according to the PA5DDR bit setting.

Module Name	Pin Function	Setting	
		I/O Port	
		PA5DDR	
I/O port	PA5 output	1	
	PA5 input (initial setting)	0	

**(4) PA4**

The pin function is switched as shown below according to the PA4DDR bit setting.

Module Name	Pin Function	Setting	
		I/O Port	
		PA4DDR	
I/O port	PA4 output	1	
	PA4 input (initial setting)	0	

**(5) PA3/SSO2**

The pin function is switched as shown below according to the combination of the SSU\_2 and the PA3DDR bit settings.

Module Name	Pin Function	Setting	
		SSU_2	
		SSO2_OE	PA3DDR
SSU_2	SSO2 output	1	—
I/O port	PA3 output	0	1
	PA3 input (initial setting)	0	0

**(6) PA2/SSI2**

The pin function is switched as shown below according to the combination of the SSU\_2 and the PA2DDR bit settings.

Module Name	Pin Function	Setting	
		SSU_2	I/O Port
		SSI2_OE	PA2DDR
SSU_2	SSI2 output	1	—
I/O port	PA2 output	0	1
	PA2 input (initial setting)	0	0

**(7) PA1/SSCK2**

The pin function is switched as shown below according to the combination of the SSU\_2 and the PA1DDR bit settings.

Module Name	Pin Function	Setting	
		SSU_2	I/O Port
		SSCK2_OE	PA1DDR
SSU_2	SSCK2 output	1	—
I/O port	PA1 output	0	1
	PA1 input (initial setting)	0	0

## 8.2.6 Port D

### (1) PD7/ $\overline{\text{SCS1}}$

The pin function is switched as shown below according to the combination of the SSU\_1 and the PD7DDR bit settings.

Module Name	Pin Function	Setting	
		SSU_2	I/O Port
		$\overline{\text{SCS1\_OE}}$	PD7DDR
SSU_1	SCS1 output	1	—
I/O port	PD7 output	0	1
	PD7 input (initial setting)	0	0

### (2) PD6/SSCK1

The pin function is switched as shown below according to the combination of the SSU\_1 and the PD6DDR bit settings.

Module Name	Pin Function	Setting	
		SSU_1	I/O Port
		SSCK1_OE	PD6DDR
SSU_1	SSCK1 output	1	—
I/O port	PD6 output	0	1
	PD6 input (initial setting)	0	0

### (3) PD5/SSI1

The pin function is switched as shown below according to the combination of the SSU\_1 and the PD5DDR bit settings.

Module Name	Pin Function	Setting	
		SSU_1	I/O Port
		SSI1_OE	PD5DDR
SSU_1	SSI1 output	1	—
I/O port	PD5 output	0	1
	PD5 input (initial setting)	0	0

**(4) PD4/SSO1**

The pin function is switched as shown below according to the combination of the SSU\_1 and the PD4DDR bit settings.

Module Name	Pin Function	Setting	
		SSU_1	I/O Port
		SSO1_OE	PD4DDR
SSU_1	SSO1 output	1	—
I/O port	PD4 output	0	1
	PD4 input (initial setting)	0	0

**(5) PD3/ $\overline{\text{SCS0}}$** 

The pin function is switched as shown below according to the combination of the SSU\_0 and the PD3DDR bit settings.

Module Name	Pin Function	Setting	
		SSU_0	I/O Port
		$\overline{\text{SCS0}}$ _OE	PD3DDR
SSU_0	$\overline{\text{SCS0}}$ output	1	—
I/O port	PD3 output	0	1
	PD3 input (initial setting)	0	0

**(6) PD2/SSCK0**

The pin function is switched as shown below according to the combination of the SSU\_0 and the PD2DDR bit settings.

Module Name	Pin Function	Setting	
		SSU_0	I/O Port
		SSCK0_OE	PD2DDR
SSU_0	SSCK0 output	1	—
I/O port	PD2 output	0	1
	PD2 input (initial setting)	0	0

**(7) PD1/SSI0**

The pin function is switched as shown below according to the combination of the SSU\_0 and the PD1DDR bit settings.

Module Name	Pin Function	Setting	
		SSU_0	I/O Port
		SSI0_OE	PD1DDR
SSU_0	SSI0 output	1	—
I/O port	PD1 output	0	1
	PD1 input (initial setting)	0	0

**(8) PD0/SSO0**

The pin function is switched as shown below according to the combination of the SSU\_0 and the PD0DDR bit settings.

Module Name	Pin Function	Setting	
		SSU_0	I/O Port
		SSO0_OE	PD0DDR
SSU_0	SSO0 output	1	—
I/O port	PD0 output	0	1
	PD0 input (initial setting)	0	0

## 8.2.7 Port H

### (1) PH7, PH6, PH5, PH4, PH3, PH2, PH1, and PH0

Port H functions as an 8-bit I/O port and also functions as a realtime input port. Using port H as the realtime input port, the pin status of port H is stored in PHRTIDR by the following triggers

a low level, a falling edge, a rising edge, or both edges of pin  $\overline{\text{IRQ14}}$ .

The pin function is switched as shown below according to the PHnDDR bit setting.

Module Name	Pin Function	Setting	
		I/O Port	PHnDDR
I/O port	PHn output	1	
	PHn input (initial setting)	0	

[Legend]

n = 7 to 0

## 8.2.8 Port J

### (1) PJ7/TIOCA8/TIOCB8/TCLKH

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_8, and PJ7DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_8	I/O Port
		TIOCB8_OE	PJ7DDR
TPU_8	TIOCB8 output	1	—
I/O port	PJ7 output	0	1
	PJ7 input (initial setting)	0	0

**(2) PJ6/TIOCA8**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_8, and PJ6DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_8	I/O Port
		TIOCA8_OE	PJ6DDR
TPU_8	TIOCA8 output	1	—
I/O port	PJ6 output	0	1
	PJ6 input (initial setting)	0	0

**(3) PJ5/TIOCA7/TIOCB7/TCLKG**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_7, and PJ5DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_7	I/O Port
		TIOCB7_OE	PJ5DDR
TPU_7	TIOCB7 output	1	—
I/O port	PJ5 output	0	1
	PJ5 input (initial setting)	0	0

**(4) PJ4/TIOCA7**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_7, and PJ4DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_7	I/O Port
		TIOCA7_OE	PJ4DDR
TPU_7	TIOCA7 output	1	—
I/O port	PJ4 output	0	1
	PJ4 input (initial setting)	0	0

**(5) PJ3/TIOCC6/TIOCD6/TCLKF**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_6, and PJ3DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_6	I/O Port
		TIOCD6_OE	PJ3DDR
TPU_6	TIOCD6 output	1	—
I/O port	PJ3 output	0	1
	PJ3 input (initial setting)	0	0

**(6) PJ2/TIOCC6/TCLKF**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_6, and PJ2DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_6	I/O Port
		TIOCC6_OE	PJ2DDR
TPU_6	TIOCC6 output	1	—
I/O port	PJ2 output	0	1
	PJ2 input (initial setting)	0	0

**(7) PJ1/TIOCA6/TIOCB6**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_6, and PJ1DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_6	I/O Port
		TIOCB6_OE	PJ1DDR
TPU_6	TIOCB6 output	1	—
I/O port	PJ1 output	0	1
	PJ1 input (initial setting)	0	0

**(8) PJ0/TIOCA6**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_6, and PJ0DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_6	I/O Port
		TIOCA6_OE	PJ0DDR
TPU_6	TIOCA6 output	1	—
I/O port	PJ0 output	0	1
	PJ0 input (initial setting)	0	0

**8.2.9 Port K****(1) PK7/TIOCA11/TIOCB11**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_11, and PK7DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_11	I/O Port
		TIOCB11_OE	PK7DDR
TPU_11	TIOCB11 output	1	—
I/O port	PK7 output	0	1
	PK7 input (initial setting)	0	0

**(2) PK6/TIOCA11**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_11, and PK6DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_11	I/O Port
		TIOCA11_OE	PK6DDR
TPU_11	TIOCA11 output	1	—
I/O port	PK6 output	0	1
	PK6 input (initial setting)	0	0

**(3) PK5/TIOCA10/TIOCB10**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_10, and PK5DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_10	I/O Port
		TIOCB10_OE	PK5DDR
TPU_10	TIOCB10 output	1	—
I/O port	PK5 output	0	1
	PK5 input (initial setting)	0	0

**(4) PK4/TIOCA10**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_10, and PK4DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_10	I/O Port
		TIOCA10_OE	PK4DDR
TPU_10	TIOCA10 output	1	—
I/O port	PK4 output	0	1
	PK4 input (initial setting)	0	0

**(5) PK3/TIOCC9/TIOCD9**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_9, and PK3DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_9	I/O Port
		TIOCD9_OE	PK3DDR
TPU_9	TIOCD9 output	1	—
I/O port	PK3 output	0	1
	PK3 input (initial setting)	0	0

**(6) PK2/TIOCC9**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_9, and PK2DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_9	I/O Port
		TIOCC9_OE	PK2DDR
TPU_6	TIOCC9 output	1	—
I/O port	PK2 output	0	1
	PK2 input (initial setting)	0	0

**(7) PK1/TIOCA6/TIOCB6**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_9, and PK1DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_9	I/O Port
		TIOCB9_OE	PK1DDR
TPU_9	TIOCB9 output	1	—
I/O port	PK1 output	0	1
	PK1 input (initial setting)	0	0

**(8) PK0/TIOCA9**

The pin function is switched as shown below according to the combination of the port function control register A (PFCRA), TPU\_9, and PK0DDR bit settings.

Module Name	Pin Function	Setting	
		TPU_9	I/O Port
		TIOCA9_OE	PK0DDR
TPU_9	TIOCA9 output	1	—
I/O port	PK0 output	0	1
	PK0 input (initial setting)	0	0

Note: \* Supported only by the H8SX/1527R.

## 8.3 Port Function Controller

The port function controller controls the I/O ports.

The port function controller incorporates the following registers.

- Port function control register 9 (PFCR9)\*
- Port function control register A (PFCRA)
- Port function control register B (PFCRB)

Note: \* PFCR9 is supported only by the H8SX/1527R.

### 8.3.1 Port Function Control Register 9 (PFCR9)

PFCR9 selects the multiple functions for the TPU (unit 0) I/O pins.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	TPUMS3A	TPUMS3B	TPUMS2	TPUMS1	TPUMS0A	TPUMS0B
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.
5	TPUMS3A	0	R/W	TPU I/O Pin Multiplex Function Select Selects TIOCA3 function 0: Specifies P21 as output compare output and input capture 1: Specifies P20 as input capture input and P21 as output compare
4	TPUMS3B	0	R/W	TPU I/O Pin Multiplex Function Select Selects TIOCC3 function 0: Specifies P22 as output compare output and input capture 1: Specifies P23 as input capture input and P22 as output compare

Bit	Bit Name	Initial Value	R/W	Description
3	TPUMS2	0	R/W	<p>TPU I/O Pin Multiplex Function Select</p> <p>Selects TIOCA2 function</p> <p>0: Specifies P36 as output compare output and input capture</p> <p>1: Specifies P37 as input capture input and P36 as output compare</p>
2	TPUMS1	0	R/W	<p>TPU I/O Pin Multiplex Function Select</p> <p>Selects TIOCA1 function</p> <p>0: Specifies P34 as output compare output and input capture</p> <p>1: Specifies P35 as input capture input and P34 as output compare</p>
1	TPUMS0A	0	R/W	<p>TPU I/O Pin Multiplex Function Select</p> <p>Selects TIOCA0 function</p> <p>0: Specifies P30 as output compare output and input capture</p> <p>1: Specifies P31 as input capture input and P30 as output compare</p>
0	TPUMS0B	0	R/W	<p>TPU I/O Pin Multiplex Function Select</p> <p>Selects TIOCC0 function</p> <p>0: Specifies P32 as output compare output and input capture</p> <p>1: Specifies P33 as input capture input and P32 as output compare</p>

### 8.3.2 Port Function Control Register A (PFCRA)

PFCRA selects the multiple functions for the TPU (unit 1) I/O pins.

Bit	7	6	5	4	3	2	1	0
Bit Name	TPUMS11	TPUMS10	TPUMS9A	TPUMS9B	TPUMS8	TPUMS7	TPUMS6A	TPUMS6B
Initial Value	0	0	0	0	0	0	0	0

1	TPUMS6A	0	R/W	<p>TPU I/O Pin Multiplex Function Select</p> <p>Selects TIOCA6 function</p> <p>0: Specifies PJ0 as output compare output and input capture</p> <p>1: Specifies PJ1 as input capture input and PJ0 as output compare</p>
0	TPUMS6B	0	R/W	<p>TPU I/O Pin Multiplex Function Select</p> <p>Selects TIOCC6 function</p> <p>0: Specifies PJ2 as output compare output and input capture</p> <p>1: Specifies PJ3 as input capture input and PJ2 as output compare</p>

### 8.3.3 Port Function Control Register B (PFCRB)

PFCRB selects the input pins for  $\overline{\text{IRQ}}14$  to  $\overline{\text{IRQ}}8$ .

Bit	7	6	5	4	3	2	1	0
Bit Name	—	ITS14	ITS13	ITS12	ITS11	ITS10	ITS9	ITS8
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	R/W	Reserved This bit is always read as 0. The write value should always be 0.
6	ITS14	0	R/W	$\overline{\text{IRQ}}14$ Pin Select Selects an input pin for $\overline{\text{IRQ}}14$ . 0: Pin P66 must not be used as $\overline{\text{IRQ}}14$ -A input 1: Pin P66 is used as $\overline{\text{IRQ}}14$ -B input
5	ITS13	0	R/W	$\overline{\text{IRQ}}13$ Pin Select Selects an input pin for $\overline{\text{IRQ}}13$ . 0: Pin P65 must not be used as $\overline{\text{IRQ}}13$ -A input 1: Pin P65 is used as $\overline{\text{IRQ}}13$ -B input
4	ITS12	0	R/W	$\overline{\text{IRQ}}12$ Pin Select Selects an input pin for $\overline{\text{IRQ}}12$ . 0: Pin P64 must not be used as $\overline{\text{IRQ}}12$ -A input 1: Pin P64 is used as $\overline{\text{IRQ}}12$ -B input
3	ITS11	0	R/W	$\overline{\text{IRQ}}11$ Pin Select Selects an input pin for $\overline{\text{IRQ}}11$ . 0: Pin P63 is used as $\overline{\text{IRQ}}11$ -A input 1: Pin P63 is used as $\overline{\text{IRQ}}11$ -B input

---

Bit	Bit Name	Initial Value	R/W	Description
2	ITS10	0	R/W	$\overline{\text{IRQ10}}$ Pin Select Selects an input pin for $\overline{\text{IRQ10}}$ . 0: Pin P22 is used as $\overline{\text{IRQ10}}$ -A input 1: Pin P62 is used as $\overline{\text{IRQ10}}$ -B input
1	ITS9	0	R/W	$\overline{\text{IRQ9}}$ Pin Select Selects an input pin for $\overline{\text{IRQ9}}$ . 0: Pin P21 is used as $\overline{\text{IRQ9}}$ -A input 1: Pin P61 is used as $\overline{\text{IRQ9}}$ -B input
0	ITS8	0	R/W	$\overline{\text{IRQ8}}$ Pin Select Selects an input pin for $\overline{\text{IRQ8}}$ . 0: Pin P20 is used as $\overline{\text{IRQ8}}$ -A input 1: Pin P60 is used as $\overline{\text{IRQ8}}$ -B input

---

## 8.4 Usage Notes

### 8.4.1 Notes on Input Buffer Control Register (ICR) Setting

- When the ICR setting is changed, the LSI may malfunction due to an edge occurred internally according to the pin states. To change the ICR setting, fix the pin high or disable the input function corresponding to the pin by setting the on-chip module registers.
- If an input is enabled by setting ICR while multiple input functions are assigned to the pin, the pin state is reflected in all the inputs of individual modules. Care must be taken for the settings of unused input function on each module side.
- When a pin is used as an output, data to be output from the pin will be latched as the pin state if the input function corresponding to the pin is enabled. To use the pin as an output, disable the input function for the pin by setting ICR.

### 8.4.2 Notes on Port Function Control Register (PFCR) Settings

- The PFC controls I/O ports. To specify the function of each pin, specify the input/output destination before enabling the input/output function.
- When the input/output destination is changed by the corresponding selection bit, an edge may occur if the previous pin level differs from the pin level after the change. To change the pin direction correctly, follow the procedure shown below.
  1. Disable the input function corresponding to the pin by the on-chip module registers.
  2. Select the input function by setting PFCR.
  3. Enable the input function.
- If a pin function has both a selection bit that modifies the input/output destination and an enable bit that enables the pin function, first specify the input/output destination by the selection bit and then enable the pin function by the enable bit.

## Section 9 16-Bit Timer Pulse Unit (TPU)

This LSI has two on-chip 16-bit timer pulse units (TPU): unit 0 and unit 1. Each unit comprises six 16-bit timer channels, that is, there are 12 timer channels in total. However, the H8SX/1525R does not include unit 0. Table 9.1 shows the unit configuration for each product.

Table 9.2 is a list of the functions and figure 9.1 is a block diagram for unit 0. Table 9.3 and figure 9.2 are for unit 1.

This section describes unit 0, which has the same functions as the other unit.

### 9.1 Features

Maximum 16-pulse input/output

Selection of eight counter input clocks for each channel

- The following operations can be set for each channel:
  - Waveform output at compare match\*
  - Input capture function\*
  - Counter clear operation
  - Synchronous operations:
    - Multiple timer counters (TCNT) can be written to simultaneously
    - Simultaneous clearing by compare match and input capture possible
    - Simultaneous input/output for registers possible by counter synchronous operation
    - Maximum of 15-phase PWM output possible by combination with synchronous operation
- Buffer operation settable for channels 0 and 3
- Phase counting mode settable independently for each of channels 1, 2, 4, and 5
- Cascaded operation
- Fast access via internal 16-bit bus
- 26 interrupt sources
- Automatic transfer of register data
- Programmable pulse generator (PPG) output trigger can be generated (supported only by unit 0)
- Conversion start trigger for the A/D converter can be generated (supported only by unit 0)
- Module stop mode can be set

Note: \* The H8SX/1527R does not have pins TIOCA4, TIOCB4, TIOCA5, and TIOCB5 for channels 4 and 5. Therefore, 0-, 1-, or toggle-output waveform and PWM waveform at an input capture input and a compare match cannot be output.

**Table 9.1 Unit Configuration for Each Product**

Product	Unit Configuration	Channel Configuration
H8SX/1527R	Unit 0	Channels 0 to 5
	Unit 1	Channels 6 to 11
H8SX/1525R	Unit 1	Channels 6 to 11

Note: \* The H8SX/1525R does not include unit 0.

O : Possible

— : Not possible

Notes: 1. The H8SX/1527R does not have pins TIOCA4, TIOCB4, TIOCA5, and TIOCB5 for channels 4 and 5. Therefore, 0-, 1-, or toggle-output waveform and PWM waveform at an input capture input and a compare match cannot be output.

2. The H8SX/1527R does not have the input capture function for channels 4 and 5.

11		TIOCA11	I/O	TGRA_11 input capture input/output compare output/PWM output pin
		TIOCB11	I/O	TGRB_11 input capture input/output compare output/PWM output pin

Note: \* The H8SX/1527R does not have pins TIOCA4, TIOCB4, TIOCA5, and TIOCB5 for channels 4 and 5.

## 9.3 Register Descriptions

The TPU has the following registers in each channel.

The registers for unit 0 and unit 1 have the same functions except bit 7 (TTGE bit for unit 0 and reserved bit for unit 1) in TIER. This section describes unit 0 registers.

Unit 0

- Channel 0:

- Timer control register\_0 (TCR\_0)
- Timer mode register\_0 (TMDR\_0)
- Timer I/O control register H\_0 (TIORH\_0)
- Timer I/O control register L\_0 (TIORL\_0)
- Timer interrupt enable register\_0 (TIER\_0)
- Timer status register\_0 (TSR\_0)
- Timer counter\_0 (TCNT\_0)
- Timer general register A\_0 (TGRA\_0)
- Timer general register B\_0 (TGRB\_0)
- Timer general register C\_0 (TGRC\_0)
- Timer general register D\_0 (TGRD\_0)

- Channel 1:

- Timer control register\_1 (TCR\_1)
- Timer mode register\_1 (TMDR\_1)
- Timer I/O control register\_1 (TIOR\_1)
- Timer interrupt enable register\_1 (TIER\_1)
- Timer status register\_1 (TSR\_1)
- Timer counter\_1 (TCNT\_1)
- Timer general register A\_1 (TGRA\_1)
- Timer general register B\_1 (TGRB\_1)

- Channel 2:
  - Timer control register\_2 (TCR\_2)
  - Timer mode register\_2 (TMDR\_2)
  - Timer I/O control register\_2 (TIOR\_2)
  - Timer interrupt enable register\_2 (TIER\_2)
  - Timer status register\_2 (TSR\_2)
  - Timer counter\_2 (TCNT\_2)
  - Timer general register A\_2 (TGRA\_2)
  - Timer general register B\_2 (TGRB\_2)
  
- Channel 3:
  - Timer control register\_3 (TCR\_3)
  - Timer mode register\_3 (TMDR\_3)
  - Timer I/O control register H\_3 (TIORH\_3)
  - Timer I/O control register L\_3 (TIORL\_3)
  - Timer interrupt enable register\_3 (TIER\_3)
  - Timer status register\_3 (TSR\_3)
  - Timer counter\_3 (TCNT\_3)
  - Timer general register A\_3 (TGRA\_3)
  - Timer general register B\_3 (TGRB\_3)
  - Timer general register C\_3 (TGRC\_3)
  - Timer general register D\_3 (TGRD\_3)
  
- Channel 4:
  - Timer control register\_4 (TCR\_4)
  - Timer mode register\_4 (TMDR\_4)
  - Timer I/O control register\_4 (TIOR\_4)
  - Timer interrupt enable register\_4 (TIER\_4)
  - Timer status register\_4 (TSR\_4)
  - Timer counter\_4 (TCNT\_4)
  - Timer general register A\_4 (TGRA\_4)
  - Timer general register B\_4 (TGRB\_4)

- Channel 5:
  - Timer control register\_5 (TCR\_5)
  - Timer mode register\_5 (TMDR\_5)
  - Timer I/O control register\_5 (TIOR\_5)
  - Timer interrupt enable register\_5 (TIER\_5)
  - Timer status register\_5 (TSR\_5)
  - Timer counter\_5 (TCNT\_5)
  - Timer general register A\_5 (TGRA\_5)
  - Timer general register B\_5 (TGRB\_5)
- Common Registers
  - Timer start register (TSTR)
  - Timer synchronous register (TSYR)

#### Unit 1

- Channel 6:
  - Timer control register\_6 (TCR\_6)
  - Timer mode register\_6 (TMDR\_6)
  - Timer I/O control register H\_6 (TIORH\_6)
  - Timer I/O control register L\_6 (TIORL\_6)
  - Timer interrupt enable register\_6 (TIER\_6)
  - Timer status register\_6 (TSR\_6)
  - Timer counter\_6 (TCNT\_6)
  - Timer general register A\_6 (TGRA\_6)
  - Timer general register B\_6 (TGRB\_6)
  - Timer general register C\_6 (TGRC\_6)
  - Timer general register D\_6 (TGRD\_6)

- Channel 7:
  - Timer control register\_7 (TCR\_7)
  - Timer mode register\_7 (TMDR\_7)
  - Timer I/O control register\_7 (TIOR\_7)
  - Timer interrupt enable register\_7 (TIER\_7)
  - Timer status register\_7 (TSR\_7)
  - Timer counter\_7 (TCNT\_7)
  - Timer general register A\_7 (TGRA\_7)
  - Timer general register B\_7 (TGRB\_7)
  
- Channel 8:
  - Timer control register\_8 (TCR\_8)
  - Timer mode register\_8 (TMDR\_8)
  - Timer I/O control register\_8 (TIOR\_8)
  - Timer interrupt enable register\_8 (TIER\_8)
  - Timer status register\_8 (TSR\_8)
  - Timer counter\_8 (TCNT\_8)
  - Timer general register A\_8 (TGRA\_8)
  - Timer general register B\_8 (TGRB\_8)
  
- Channel 9:
  - Timer control register\_9 (TCR\_9)
  - Timer mode register\_9 (TMDR\_9)
  - Timer I/O control register H\_9 (TIORH\_9)
  - Timer I/O control register L\_9 (TIORL\_9)
  - Timer interrupt enable register\_9 (TIER\_9)
  - Timer status register\_9 (TSR\_9)
  - Timer counter\_9 (TCNT\_9)
  - Timer general register A\_9 (TGRA\_9)
  - Timer general register B\_9 (TGRB\_9)
  - Timer general register C\_9 (TGRC\_9)
  - Timer general register D\_9 (TGRD\_9)

- Channel 10:
  - Timer control register\_10 (TCR\_10)
  - Timer mode register\_10 (TMDR\_10)
  - Timer I/O control register \_10 (TIOR\_10)
  - Timer interrupt enable register\_10 (TIER\_10)
  - Timer status register\_10 (TSR\_10)
  - Timer counter\_10 (TCNT\_10)
  - Timer general register A\_10 (TGRA\_10)
  - Timer general register B\_10 (TGRB\_10)
- Channel 11:
  - Timer control register\_11 (TCR\_11)
  - Timer mode register\_11 (TMDR\_11)
  - Timer I/O control register\_11 (TIOR\_11)
  - Timer interrupt enable register\_11 (TIER\_11)
  - Timer status register\_11 (TSR\_11)
  - Timer counter\_11 (TCNT\_11)
  - Timer general register A\_11 (TGRA\_11)
  - Timer general register B\_11 (TGRB\_11)
- Common Registers
  - Timer start register (TSTRB)
  - Timer synchronous register (TSYRB)

### 9.3.1 Timer Control Register (TCR)

TCR controls the TCNT operation for each channel. The TPU has a total of six TCR registers, one for each channel. TCR register settings should be made only while TCNT operation is stopped.

Bit	7	6	5	4	3	2	1	0
Bit Name	CCLR2	CCLR1	CCLR0	CKEG1	CKEG0	TPSC2	TPSC1	TPSC0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	CCLR2	0	R/W	Counter Clear 2 to 0
6	CCLR1	0	R/W	These bits select the TCNT counter clearing source. See tables 9.5 and 9.6 for details.
5	CCLR0	0	R/W	
4	CKEG1	0	R/W	Clock Edge 1 and 0
3	CKEG0	0	R/W	These bits select the input clock edge. For details, see table 9.7. When the input clock is counted using both edges, the input clock period is halved (e.g. $P\phi/4$ both edges = $P\phi/2$ rising edge). If phase counting mode is used on channels 1, 2, 4, and 5, this setting is ignored and the phase counting mode setting has priority. Internal clock edge selection is valid when the input clock is $P\phi/4$ or slower. This setting is ignored if the input clock is $P\phi/1$ , or when overflow/underflow of another channel is selected.
2	TPSC2	0	R/W	
1	TPSC1	0	R/W	These bits select the TCNT counter clock. The clock source can be selected independently for each channel. See tables 9.8 to 9.13 for details. To select the external clock as the clock source, the DDR bit and ICR bit for the corresponding pin should be set to 0 and 1, respectively. For details, see section 8, I/O Ports.
0	TPSC0	0	R/W	

**Table 9.5 CCLR2 to CCLR0 (Channels 0 and 3)**

Channel	Bit 7 CCLR2	Bit 6 CCLR1	Bit 5 CCLR0	Description
0, 3	0	0	0	TCNT clearing disabled
	0	0	1	TCNT cleared by TGRA compare match/input capture
	0	1	0	TCNT cleared by TGRB compare match/input capture
	0	1	1	TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation* <sup>1</sup>
	1	0	0	TCNT clearing disabled
	1	0	1	TCNT cleared by TGRC compare match/input capture* <sup>2</sup>
	1	1	0	TCNT cleared by TGRD compare match/input capture* <sup>2</sup>
	1	1	1	TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation* <sup>1</sup>

- Notes: 1. Synchronous operation is selected by setting the SYNC bit in TSYR to 1.  
2. When TGRC or TGRD is used as a buffer register, TCNT is not cleared because the buffer register setting has priority, and compare match/input capture does not occur.

**Table 9.6 CCLR2 to CCLR0 (Channels 1, 2, 4, and 5)**

Channel	Bit 7* <sup>2</sup> Reserved	Bit 6 CCLR1	Bit 5 CCLR0	Description
1, 2, 4, 5	0	0	0	TCNT clearing disabled
	0	0	1	TCNT cleared by TGRA compare match/input capture
	0	1	0	TCNT cleared by TGRB compare match/input capture
	0	1	1	TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation* <sup>1</sup>

- Notes: 1. Synchronous operation is selected by setting the SYNC bit in TSYR to 1.  
2. Bit 7 is reserved in channels 1, 2, 4, and 5. It is a read-only bit and cannot be modified.

**Table 9.7 Input Clock Edge Selection**

Clock Edge Selection		Input Clock	
CKEG1	CKEG0	Internal Clock	External Clock
0	0	Counted at falling edge	Counted at rising edge
0	1	Counted at rising edge	Counted at falling edge
1	X	Counted at both edges	Counted at both edges

[Legend]

X: Don't care

**Table 9.8 TPSC2 to TPSC0 (Channel 0)**

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
0	0	0	0	Internal clock: counts on P $\phi$ /1
	0	0	1	Internal clock: counts on P $\phi$ /4
	0	1	0	Internal clock: counts on P $\phi$ /16
	0	1	1	Internal clock: counts on P $\phi$ /64
	1	0	0	External clock: counts on TCLKA pin input
	1	0	1	External clock: counts on TCLKB pin input
	1	1	0	External clock: counts on TCLKC pin input
	1	1	1	External clock: counts on TCLKD pin input

**Table 9.9 TPSC2 to TPSC0 (Channel 1)**

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
1	0	0	0	Internal clock: counts on P $\phi$ /1
	0	0	1	Internal clock: counts on P $\phi$ /4
	0	1	0	Internal clock: counts on P $\phi$ /16
	0	1	1	Internal clock: counts on P $\phi$ /64
	1	0	0	External clock: counts on TCLKA pin input
	1	0	1	External clock: counts on TCLKB pin input
	1	1	0	Internal clock: counts on P $\phi$ /256
	1	1	1	Counts on TCNT2 overflow/underflow

Note: This setting is ignored when channel 1 is in phase counting mode.

**Table 9.10 TPSC2 to TPSC0 (Channel 2)**

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
2	0	0	0	Internal clock: counts on P $\phi$ /1
	0	0	1	Internal clock: counts on P $\phi$ /4
	0	1	0	Internal clock: counts on P $\phi$ /16
	0	1	1	Internal clock: counts on P $\phi$ /64
	1	0	0	External clock: counts on TCLKA pin input
	1	0	1	External clock: counts on TCLKB pin input
	1	1	0	External clock: counts on TCLKC pin input
	1	1	1	Internal clock: counts on P $\phi$ /1024

Note: This setting is ignored when channel 2 is in phase counting mode.

**Table 9.11 TPSC2 to TPSC0 (Channel 3)**

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
3	0	0	0	Internal clock: counts on P $\phi$ /1
	0	0	1	Internal clock: counts on P $\phi$ /4
	0	1	0	Internal clock: counts on P $\phi$ /16
	0	1	1	Internal clock: counts on P $\phi$ /64
	1	0	0	External clock: counts on TCLKA pin input
	1	0	1	Internal clock: counts on P $\phi$ /1024
	1	1	0	Internal clock: counts on P $\phi$ /256
	1	1	1	Internal clock: counts on P $\phi$ /4096

**Table 9.12 TPSC2 to TPSC0 (Channel 4)**

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
4	0	0	0	Internal clock: counts on P $\phi$ /1
	0	0	1	Internal clock: counts on P $\phi$ /4
	0	1	0	Internal clock: counts on P $\phi$ /16
	0	1	1	Internal clock: counts on P $\phi$ /64
	1	0	0	External clock: counts on TCLKA pin input
	1	0	1	External clock: counts on TCLKC pin input
	1	1	0	Internal clock: counts on P $\phi$ /1024
	1	1	1	Counts on TCNT5 overflow/underflow

Note: This setting is ignored when channel 4 is in phase counting mode.

**Table 9.13 TPSC2 to TPSC0 (Channel 5)**

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
5	0	0	0	Internal clock: counts on P $\phi$ /1
	0	0	1	Internal clock: counts on P $\phi$ /4
	0	1	0	Internal clock: counts on P $\phi$ /16
	0	1	1	Internal clock: counts on P $\phi$ /64
	1	0	0	External clock: counts on TCLKA pin input
	1	0	1	External clock: counts on TCLKC pin input
	1	1	0	Internal clock: counts on P $\phi$ /256
	1	1	1	External clock: counts on TCLKD pin input

Note: This setting is ignored when channel 5 is in phase counting mode.

### 9.3.2 Timer Mode Register (TMDR)

TMDR sets the operating mode for each channel. The TPU has six TMDR registers, one for each channel. TMDR register settings should be made only while TCNT operation is stopped.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	BFB	BFA	MD3	MD2	MD1	MD0
Initial Value	1	1	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 1	R	Reserved These are read-only bits and cannot be modified.
5	BFB	0	R/W	Buffer Operation B Specifies whether TGRB is to normally operate, or TGRB and TGRD are to be used together for buffer operation. When TGRD is used as a buffer register, TGRD input capture/output compare is not generated. In channels 1, 2, 4, and 5, which have no TGRD, bit 5 is reserved. It is a read-only bit and cannot be modified. 0: TGRB operates normally 1: TGRB and TGRD used together for buffer operation
4	BFA	0	R/W	Buffer Operation A Specifies whether TGRA is to normally operate, or TGRA and TGRC are to be used together for buffer operation. When TGRC is used as a buffer register, TGRC input capture/output compare is not generated. In channels 1, 2, 4, and 5, which have no TGRC, bit 4 is reserved. It is a read-only bit and cannot be modified. 0: TGRA operates normally 1: TGRA and TGRC used together for buffer operation
3	MD3	0	R/W	Modes 3 to 0
2	MD2	0	R/W	Set the timer operating mode.
1	MD1	0	R/W	MD3 is a reserved bit. The write value should always be 0. See table 9.14 for details.
0	MD0	0	R/W	

**Table 9.14 MD3 to MD0**

Bit 3 MD3* <sup>1</sup>	Bit 2 MD2* <sup>2</sup>	Bit 1 MD1	Bit 0 MD0	Description
0	0	0	0	Normal operation
0	0	0	1	Reserved
0	0	1	0	PWM mode 1
0	0	1	1	PWM mode 2
0	1	0	0	Phase counting mode 1
0	1	0	1	Phase counting mode 2
0	1	1	0	Phase counting mode 3
0	1	1	1	Phase counting mode 4
1	X	X	X	—

[Legend]

X: Don't care

- Notes: 1. MD3 is a reserved bit. The write value should always be 0.  
 2. Phase counting mode cannot be set for channels 0 and 3. In this case, the write value should always be 0.

### 9.3.3 Timer I/O Control Register (TIOR)

TIOR controls TGR. The TPU has eight TIOR registers, two each for channels 0 and 3, and one each for channels 1, 2, 4, and 5. Care is required since TIOR is affected by the TMDR setting.

The initial output specified by TIOR is valid when the counter is stopped (the CST bit in TSTR is cleared to 0). Note also that, in PWM mode 2, the output at the point at which the counter is cleared to 0 is specified.

When TGRC or TGRD is designated for buffer operation, this setting is invalid and the register operates as a buffer register.

To designate the input capture pin in TIOR, the DDR bit and ICR bit for the corresponding pin should be set to 0 and 1, respectively. For details, see section 8, I/O Ports.

Note: The H8SX/1527R does not include TIOR\_4 and TIOR\_5.

- TIORH\_0, TIOR\_1, TIOR\_2, TIORH\_3, TIOR\_4, TIOR\_5

Bit	7	6	5	4	3	2	1	0
Bit Name	IOB3	IOB2	IOB1	IOB0	IOA3	IOA2	IOA1	IOA0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

- TIORL\_0, TORL\_3

Bit	7	6	5	4	3	2	1	0
Bit Name	IOD3	IOD2	IOD1	IOD0	IOC3	IOC2	IOC1	IOC0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

- TIORH\_0, TIOR\_1, TIOR\_2, TIORH\_3, TIOR\_4, TIOR\_5

Bit	Bit Name	Initial Value	R/W	Description
7	IOB3	0	R/W	I/O Control B3 to B0
6	IOB2	0	R/W	Specify the function of TGRB.
5	IOB1	0	R/W	For details, see tables 9.15, 9.17, 9.18, 9.19, 9.21, and 9.22.
4	IOB0	0	R/W	
3	IOA3	0	R/W	I/O Control A3 to A0
2	IOA2	0	R/W	Specify the function of TGRA.
1	IOA1	0	R/W	For details, see tables 9.23, 9.25, 9.26, 9.27, 9.29, and 9.30.
0	IOA0	0	R/W	

- TIORL\_0, TIORL\_3:

Bit	Bit Name	Initial Value	R/W	Description
7	IOD3	0	R/W	I/O Control D3 to D0
6	IOD2	0	R/W	Specify the function of TGRD.
5	IOD1	0	R/W	For details, see tables 9.16, and 9.20.
4	IOD0	0	R/W	
3	IOC3	0	R/W	I/O Control C3 to C0
2	IOC2	0	R/W	Specify the function of TGRC.
1	IOC1	0	R/W	For details, see tables 9.24, and 9.28.
0	IOC0	0	R/W	

**Table 9.15 TIORH\_0**

Bit 7 IOB3	Bit 6 IOB2	Bit 5 IOB1	Bit 4 IOB0	Description		
				TGRB_0 Function	TIOCB0 Pin Function	
0	0	0	0	Output compare register	Output disabled

### 9.3.4 Timer Interrupt Enable Register (TIER)

TIER controls enabling or disabling of interrupt requests for each channel. The TPU has six TIER registers, one for each channel.

Bit	7	6	5	4	3	2	1	0
Bit Name	TTGE*	—	TCIEU	TCIEV	TGIED	TGIEC	TGIEB	TGIEA
Initial Value	0	1	0	0	0	0	0	0
R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W

Note: \* Bit 7 in TIER for unit 1 is a reserved bit and is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial value	R/W	Description
7	TTGE*	0	R/W	<p>A/D Conversion Start Request Enable</p> <p>Enables/disables generation of A/D conversion start requests by TGRA input capture/compare match.</p> <p>0: A/D conversion start request generation disabled</p> <p>1: A/D conversion start request generation enabled</p>
6	—	1	R	<p>Reserved</p> <p>This is a read-only bit and cannot be modified.</p>

Note: \* Bit 7 in TIER for unit 1 is a reserved bit and is always read as 0. The write value should always be 0.

### 9.3.5 Timer Status Register (TSR)

TSR indicates the status of each channel. The TPU has six TSR registers, one for each channel.

Bit	7	6	5	4	3	2	1	0
Bit Name	TCFD	—	TCFU	TCFV	TGFD	TGFC	TGFB	TGFA
Initial Value	1	1	0	0	0	0	0	0
R/W	R	R	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*

Note: \* Only 0 can be written to bits 5 to 0, to clear flags.

Bit	Bit Name	Initial value	R/W	Description
7	TCFD	1	R	<p>Count Direction Flag</p> <p>Status flag that shows the direction in which TCNT counts in channels 1, 2, 4, and 5.</p> <p>In channels 0 and 3, bit 7 is reserved. It is a read-only bit and cannot be modified.</p> <p>0: TCNT counts down</p> <p>1: TCNT counts up</p>
6	—	1	R	<p>Reserved</p> <p>This is a read-only bit and cannot be modified.</p>

It is a read-only bit and cannot be modified.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>When the TCNT value underflows (changes from H'0000 to H'FFFF)</li> </ul> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>When a 0 is written to TCFU after reading TCFU = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> </ul>

Bit	Bit Name	Initial value	R/W	Description
4	TCFV	0	R/(W)*	<p>Overflow Flag</p> <p>Status flag that indicates that a TCNT overflow has occurred.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>When the TCNT value overflows (changes from H'FFFF to H'0000)</li> </ul> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>When a 0 is written to TCFV after reading TCFV = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> </ul>
3	TGFD	0	R/(W)*	<p>Input Capture/Output Compare Flag D</p> <p>Status flag that indicates the occurrence of TGRD input capture or compare match in channels 0 and 3.</p> <p>In channels 1, 2, 4, and 5, bit 3 is reserved. It is a read-only bit and cannot be modified.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>When TCNT = TGRD while TGRD is functioning as output compare register</li> <li>When TCNT value is transferred to TGRD by input capture signal while TGRD is functioning as input capture register</li> </ul> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>When 0 is written to TGFD after reading TGFD = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> </ul>

Bit	Bit Name	Initial value	R/W	Description
2	TGFC	0	R/(W)*	<p>Input Capture/Output Compare Flag C</p> <p>Status flag that indicates the occurrence of TGRC input capture or compare match in channels 0 and 3.</p> <p>In channels 1, 2, 4, and 5, bit 2 is reserved. It is a read-only bit and cannot be modified.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>• When TCNT = TGRC while TGRC is functioning as output compare register</li> <li>• When TCNT value is transferred to TGRC by input capture signal while TGRC is functioning as input capture register</li> </ul> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>• When 0 is written to TGFC after reading TGFC = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> </ul>
1	TGFB	0	R/(W)*	<p>Input Capture/Output Compare Flag B</p> <p>Status flag that indicates the occurrence of TGRB input capture or compare match.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>• When TCNT = TGRB while TGRB is functioning as output compare register</li> <li>• When TCNT value is transferred to TGRB by input capture signal while TGRB is functioning as input capture register</li> </ul> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>• When 0 is written to TGFB after reading TGFB = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> </ul>

Bit	Bit Name	Initial value	R/W	Description
0	TGFA	0	R/(W)*	<p>Input Capture/Output Compare Flag A</p> <p>Status flag that indicates the occurrence of TGRA input capture or compare match.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>• When TCNT = TGRA while TGRA is functioning as output compare register</li> <li>• When TCNT value is transferred to TGRA by input capture signal while TGRA is functioning as input capture register</li> </ul> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• When DMAC is activated by a TGIA interrupt while the DTA bit in DMDR of DMAC is 1</li> <li>• When 0 is written to TGFA after reading TGFA = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> </ul>

Note: \* Only 0 can be written to clear the flag.

### 9.3.6 Timer Counter (TCNT)

TCNT is a 16-bit readable/writable counter. The TPU has six TCNT counters, one for each channel.

TCNT is initialized to H'0000 by a reset or in hardware standby mode.

TCNT cannot be accessed in 8-bit units. TCNT must always be accessed in 16-bit units.

Bit	15	14	13	12	11	10	9	8
Bit Name								
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	7	6	5	4	3	2	1	0
Bit Name								
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

### 9.3.7 Timer General Register (TGR)

TGR is a 16-bit readable/writable register with a dual function as output compare and input capture registers. The TPU has 16 TGR registers, four each for channels 0 and 3 and two each for channels 1, 2, 4, and 5. TGRC and TGRD for channels 0 and 3 can also be designated for operation as buffer registers. The TGR registers cannot be accessed in 8-bit units; they must always be accessed in 16-bit units. TGR and buffer register combinations during buffer operations are TGRA–TGRC and TGRB–TGRD.

Bit	15	14	13	12	11	10	9	8
Bit Name								
Initial Value	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	7	6	5	4	3	2	1	0
Bit Name								
Initial Value	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

### 9.3.8 Timer Start Register (TSTR)

TSTR starts or stops operation for channels 0 to 5. When setting the operating mode in TMDR or setting the count clock in TCR, first stop the TCNT counter.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	CST5	CST4	CST3	CST2	CST1	CST0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial value	R/W	Description
7, 6	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.
5	CST5	0	R/W	Counter Start 5 to 0
4	CST4	0	R/W	These bits select operation or stoppage for TCNT.
3	CST3	0	R/W	If 0 is written to the CST bit during operation with the TIOC pin designated for output, the counter stops but the TIOC pin output compare output level is retained. If TIOR is written to when the CST bit is cleared to 0, the pin output level will be changed to the set initial output value.
2	CST2	0	R/W	
1	CST1	0	R/W	0: TCNT_5 to TCNT_0 count operation is stopped 1: TCNT_5 to TCNT_0 performs count operation
0	CST0	0	R/W	

### 9.3.9 Timer Synchronous Register (TSYR)

TSYR selects independent operation or synchronous operation for the TCNT counters of channels 0 to 5. A channel performs synchronous operation when the corresponding bit in TSYR is set to 1.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	SYNC5	SYNC4	SYNC3	SYNC2	SYNC1	SYNC0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial value	R/W	Description
7, 6	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.
5	SYNC5	0	R/W	Timer Synchronization 5 to 0
4	SYNC4	0	R/W	These bits select whether operation is independent of or synchronized with other channels.
3	SYNC3	0	R/W	When synchronous operation is selected, synchronous presetting of multiple channels, and synchronous clearing through counter clearing on another channel are possible.
2	SYNC2	0	R/W	
1	SYNC1	0	R/W	
0	SYNC0	0	R/W	To set synchronous operation, the SYNC bits for at least two channels must be set to 1. To set synchronous clearing, in addition to the SYNC bit, the TCNT clearing source must also be set by means of bits CCLR2 to CCLR0 in TCR. 0: TCNT_5 to TCNT_0 operate independently (TCNT presetting/clearing is unrelated to other channels) 1: TCNT_5 to TCNT_0 perform synchronous operation (TCNT synchronous presetting/synchronous clearing is possible)

## 9.4 Operation

### 9.4.1 Basic Functions

Each channel has a TCNT and TGR register. TCNT performs up-counting, and is also capable of free-running operation, periodic counting, and external event counting.

Each TGR can be used as an input capture register or output compare register.

#### (1) Counter Operation

When one of bits CST0 to CST5 is set to 1 in TSTR, the TCNT counter for the corresponding channel starts counting. TCNT can operate as a free-running counter, periodic counter, and so on.

##### (a) Example of count operation setting procedure

Figure 9.3 shows an example of the count operation setting procedure.

**Figure 9.3 Example of Counter Operation Setting Procedure**

**(b) Free-running count operation and periodic count operation**

Immediately after a reset, the TPU's TCNT counters are all designated as free-running counters. When the relevant bit in TSTR is set to 1 the corresponding TCNT counter starts up-count operation as a free-running counter. When TCNT overflows (changes from H'FFFF to H'0000), the TCFV bit in TSR is set to 1. If the value of the corresponding TCIEV bit in TIER is 1 at this point, the TPU requests an interrupt. After overflow, TCNT starts counting up again from H'0000.

Figure 9.4 illustrates free-running counter operation.

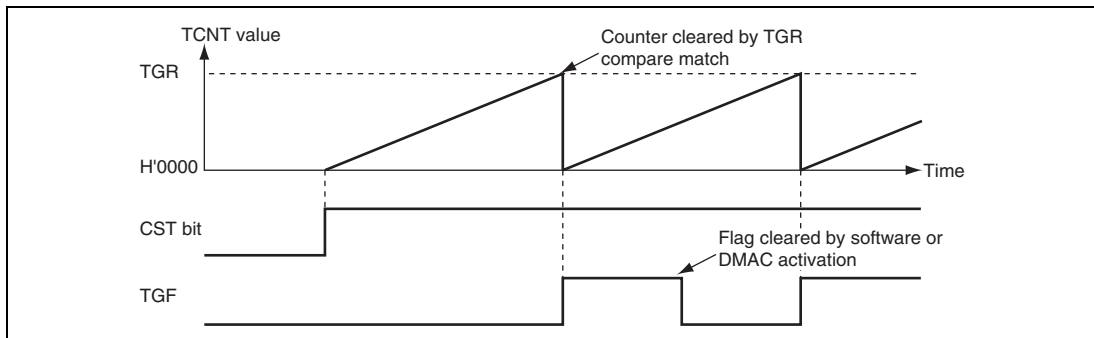

**Figure 9.4 Free-Running Counter Operation**

When compare match is selected as the TCNT clearing source, the TCNT counter for the relevant channel performs periodic count operation. The TGR register for setting the period is designated as an output compare register, and counter clearing by compare match is selected by means of bits CCLR2 to CCLR0 in TCR. After the settings have been made, TCNT starts count-up operation as a periodic counter when the corresponding bit in TSTR is set to 1. When the count value matches the value in TGR, the TGF bit in TSR is set to 1 and TCNT is cleared to H'0000.

If the value of the corresponding TGIE bit in TIER is 1 at this point, the TPU requests an interrupt. After a compare match, TCNT starts counting up again from H'0000.

Figure 9.5 illustrates periodic counter operation.

**Figure 9.5 Periodic Counter Operation**

## (2) Waveform Output by Compare Match

The TPU can perform 0, 1, or toggle output from the corresponding output pin using a compare match.

Note: \* The H8SX/1527R does not have pins TIOCA4, TIOCB4, TIOCA5, and TIOCB5 for channels 4 and 5. Therefore, 0-, 1-, or toggle-output waveform and PWM waveform at an input capture input and a compare match cannot be output.

### (a) Example of setting procedure for waveform output by compare match

Figure 9.6 shows an example of the setting procedure for waveform output by a compare match.

**Figure 9.6 Example of Setting Procedure for Waveform Output by Compare Match**

**(b) Examples of waveform output operation**

Figure 9.7 shows an example of 0-output and 1-output.

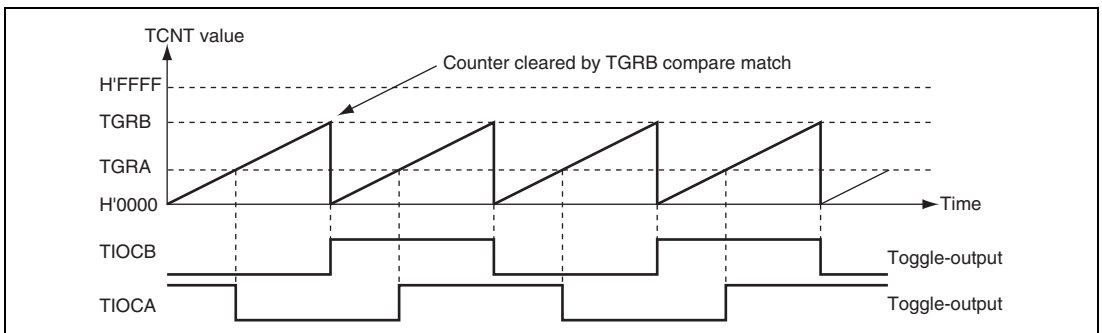

In this example, TCNT has been designated as a free-running counter, and settings have been made so that 1 is output by compare match A, and 0 is output by compare match B. When the set level and the pin level match, the pin level does not change.

**Figure 9.7 Example of 0-Output/1-Output Operation**

Figure 9.8 shows an example of toggle output.

In this example, TCNT has been designated as a periodic counter (with counter clearing performed by compare match B), and settings have been made so that output is toggled by both compare match A and compare match B.

**Figure 9.8 Example of Toggle Output Operation**

### (3) Input Capture Function

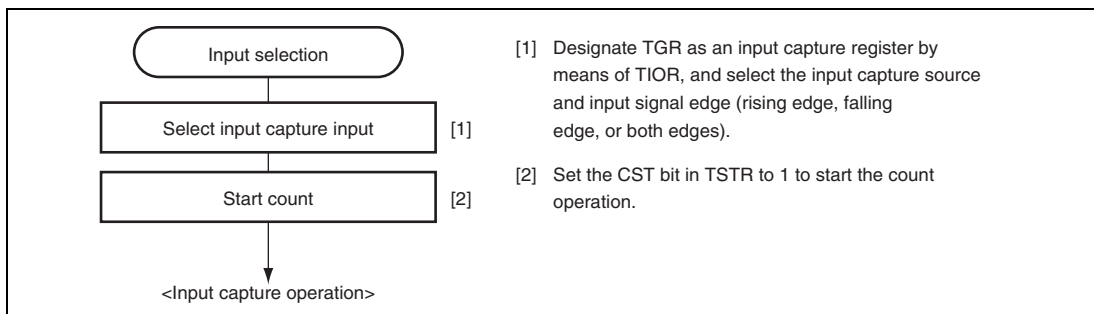

The TCNT value can be transferred to TGR on detection of the TIOC pin input edge.

Rising edge, falling edge, or both edges can be selected as the detection edge. For channels 0, 1, 3, and 4, it is also possible to specify another channel's counter input clock or compare match signal as the input capture source.

Note: When another channel's counter input clock is used as the input capture input for channels 0 and 3,  $P\phi/1$  should not be selected as the counter input clock used for input capture input. Input capture will not be generated if  $P\phi/1$  is selected.

#### (a) Example of setting procedure for input capture operation

Figure 9.9 shows an example of the setting procedure for input capture operation.

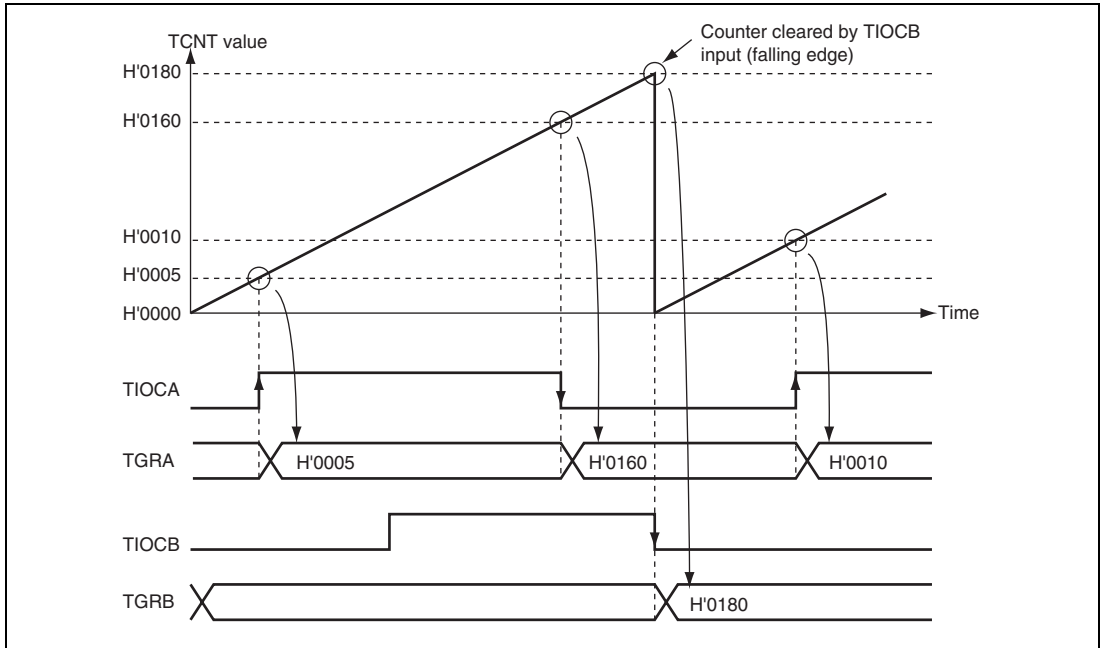

**Figure 9.9 Example of Setting Procedure for Input Capture Operation**

**(b) Example of input capture operation**

Figure 9.10 shows an example of input capture operation.

In this example, both rising and falling edges have been selected as the TIOCA pin input capture input edge, falling edge has been selected as the TIOCB pin input capture input edge, and counter clearing by TGRB input capture has been designated for TCNT.

**Figure 9.10 Example of Input Capture Operation**

## 9.4.2 Synchronous Operation

In synchronous operation, the values in multiple TCNT counters can be rewritten simultaneously (synchronous presetting). Also, multiple TCNT counters can be cleared simultaneously (synchronous clearing) by making the appropriate setting in TCR.

Synchronous operation enables TGR to be incremented with respect to a single time base.

Channels 0 to 5 can all be designated for synchronous operation.

### (1) Example of Synchronous Operation Setting Procedure

Figure 9.11 shows an example of the synchronous operation setting procedure.

**Figure 9.11 Example of Synchronous Operation Setting Procedure**

## (2) Example of Synchronous Operation

Figure 9.12 shows an example of synchronous operation.

In this example, synchronous operation and PWM mode 1 have been designated for channels 0 to 2, TGRB\_0 compare match has been set as the channel 0 counter clearing source, and synchronous clearing has been set for the channel 1 and 2 counter clearing source.

Three-phase PWM waveforms are output from pins TIOCA0, TIOCA1, and TIOCA2. At this time, synchronous presetting and synchronous clearing by TGRB\_0 compare match are performed for channel 0 to 2 TCNT counters, and the data set in TGRB\_0 is used as the PWM cycle.

For details on PWM modes, see section 9.4.5, PWM Modes.

**Figure 9.12 Example of Synchronous Operation**

### 9.4.3 Buffer Operation

Buffer operation, provided for channels 0 and 3, enables TGRC and TGRD to be used as buffer registers.

Buffer operation differs depending on whether TGR has been designated as an input capture register or a compare match register.

Table 9.31 shows the register combinations used in buffer operation.

**Table 9.31 Register Combinations in Buffer Operation**

Channel	Timer General Register	Buffer Register
0	TGRA_0	TGRC_0
	TGRB_0	TGRD_0
3	TGRA_3	TGRC_3
	TGRB_3	TGRD_3

- When TGR is an output compare register

When a compare match occurs, the value in the buffer register for the corresponding channel is transferred to the timer general register.

This operation is illustrated in figure 9.13.

**Figure 9.13 Compare Match Buffer Operation**

- When TGR is an input capture register

When input capture occurs, the value in TCNT is transferred to TGR and the value previously held in TGR is transferred to the buffer register.

This operation is illustrated in figure 9.14.

**Figure 9.14 Input Capture Buffer Operation**

### (1) Example of Buffer Operation Setting Procedure

Figure 9.15 shows an example of the buffer operation setting procedure.

**Figure 9.15 Example of Buffer Operation Setting Procedure**

## (2) Examples of Buffer Operation

### (a) When TGR is an output compare register

Figure 9.16 shows an operation example in which PWM mode 1 has been designated for channel 0, and buffer operation has been designated for TGRA and TGRC. The settings used in this example are TCNT clearing by compare match B, 1 output at compare match A, and 0 output at compare match B.

As buffer operation has been set, when compare match A occurs, the output changes and the value in buffer register TGRC is simultaneously transferred to timer general register TGRA. This operation is repeated each time compare match A occurs.

For details on PWM modes, see section 9.4.5, PWM Modes.

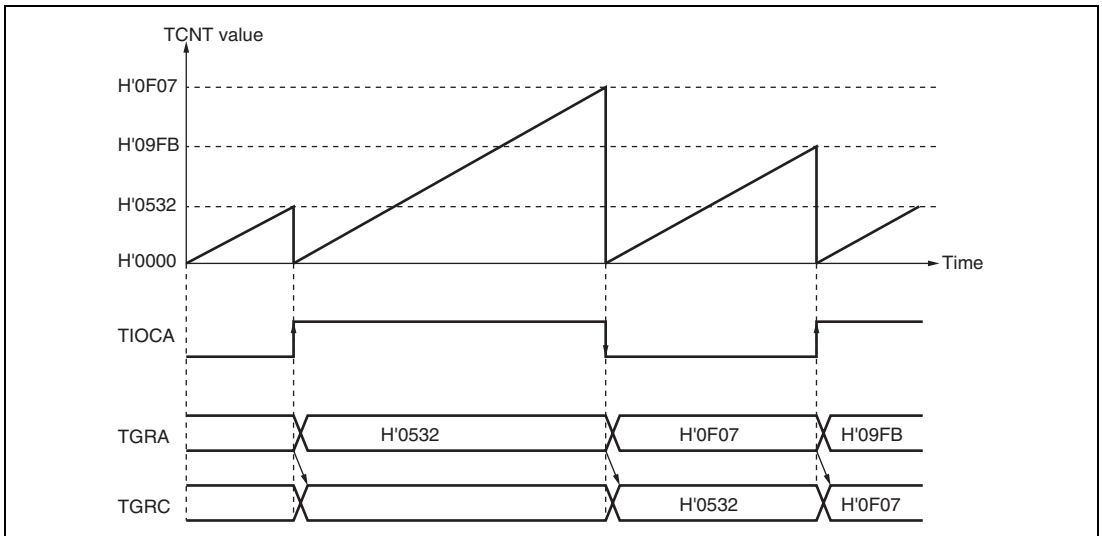

**Figure 9.16 Example of Buffer Operation (1)**

**(b) When TGR is an input capture register**

Figure 9.17 shows an operation example in which TGRA has been designated as an input capture register, and buffer operation has been designated for TGRA and TGRC.

Counter clearing by TGRA input capture has been set for TCNT, and both rising and falling edges have been selected as the TIOCA pin input capture input edge.

As buffer operation has been set, when the TCNT value is stored in TGRA upon occurrence of input capture A, the value previously stored in TGRA is simultaneously transferred to TGRC.

**Figure 9.17 Example of Buffer Operation (2)**

### 9.4.4 Cascaded Operation

In cascaded operation, two 16-bit counters for different channels are used together as a 32-bit counter.

This function works by counting the channel 1 (channel 4) counter clock at overflow/underflow of TCNT\_2 (TCNT\_5) as set in bits TPSC2 to TPSC0 in TCR.

Underflow occurs only when the lower 16-bit TCNT is in phase-counting mode.

Table 9.32 shows the register combinations used in cascaded operation.

Note: When phase counting mode is set for channel 1 or 4, the counter clock setting is invalid and the counter operates independently in phase counting mode.

**Table 9.32 Cascaded Combinations**

Combination	Upper 16 Bits	Lower 16 Bits
Channels 1 and 2	TCNT_1	TCNT_2
Channels 4 and 5	TCNT_4	TCNT_5

#### (1) Example of Cascaded Operation Setting Procedure

Figure 9.18 shows an example of the setting procedure for cascaded operation.

**Figure 9.18 Example of Cascaded Operation Setting Procedure**

## (2) Examples of Cascaded Operation

Figure 9.19 illustrates the operation when counting upon TCNT\_2 overflow/underflow has been set for TCNT\_1, TGRA\_1 and TGRA\_2 have been designated as input capture registers, and the TIOC pin rising edge has been selected.

When a rising edge is input to the TIOCA1 and TIOCA2 pins simultaneously, the upper 16 bits of the 32-bit data are transferred to TGRA\_1, and the lower 16 bits to TGRA\_2.

**Figure 9.19 Example of Cascaded Operation (1)**

Figure 9.20 illustrates the operation when counting upon TCNT\_2 overflow/underflow has been set for TCNT\_1, and phase counting mode has been designated for channel 2.

TCNT\_1 is incremented by TCNT\_2 overflow and decremented by TCNT\_2 underflow.

**Figure 9.20 Example of Cascaded Operation (2)**

### 9.4.5 PWM Modes

In PWM mode, PWM waveforms are output from the output pins. 0-, 1-, or toggle-output can be selected as the output level in response to compare match of each TGR.

Settings of TGR registers can output a PWM waveform in the range of 0% to 100% duty cycle.

Designating TGR compare match as the counter clearing source enables the cycle to be set in that register. All channels can be designated for PWM mode independently. Synchronous operation is also possible.

There are two PWM modes, as described below.

#### (1) PWM mode 1

PWM output is generated from the TIOCA and TIOCC pins by pairing TGRA with TGRB and TGRC with TGRD. The outputs specified by bits IOA3 to IOA0 and IOC3 to IOC0 in TIOR are output from the TIOCA and TIOCC pins at compare matches A and C, respectively. The outputs specified by bits IOB3 to IOB0 and IOD3 to IOD0 in TIOR are output at compare matches B and D, respectively. The initial output value is the value set in TGRA or TGRC. If the set values of paired TGRs are identical, the output value does not change when a compare match occurs.

In PWM mode 1, a maximum 8-phase PWM output is possible.

**(2) PWM mode 2**

PWM output is generated using one TGR as the cycle register and the others as duty cycle registers. The output specified in TIOR is performed by means of compare matches. Upon counter clearing by a cycle register compare match, the output value of each pin is the initial value set in TIOR. If the set values of the cycle and duty cycle registers are identical, the output value does not change when a compare match occurs.

In PWM mode 2, a maximum 15-phase PWM output is possible by combined use with synchronous operation.

The correspondence between PWM output pins and registers is shown in table 9.33.

**Table 9.33 PWM Output Registers and Output Pins**

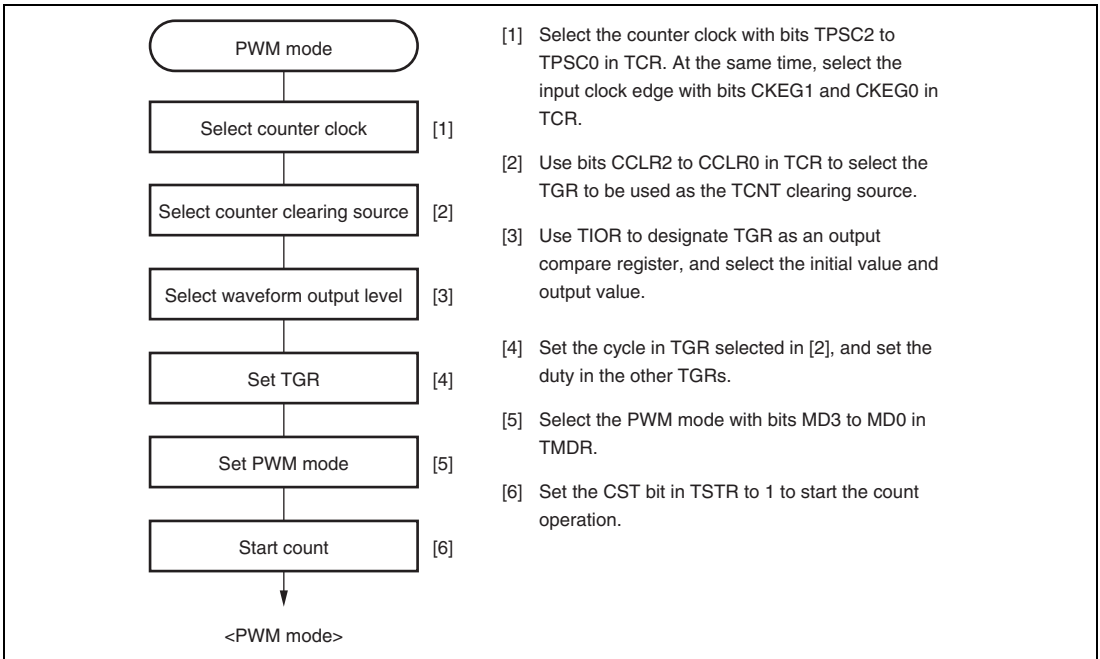

Channel	Registers	Output Pins	
		PWM Mode 1	PWM Mode 2
0	TGRA_0	TIOCA0	TIOCA0
	TGRB_0		TIOCB0
	TGRC_0	TIOCC0	TIOCC0
	TGRD_0		TIOCD0
1	TGRA_1	TIOCA1	TIOCA1
	TGRB_1		TIOCB1
2	TGRA_2	TIOCA2	TIOCA2
	TGRB_2		TIOCB2
3	TGRA_3	TIOCA3	TIOCA3
	TGRB_3		TIOCB3
	TGRC_3	TIOCC3	TIOCC3
	TGRD_3		TIOCD3
4	TGRA_4	TIOCA4	TIOCA4
	TGRB_4		TIOCB4
5	TGRA_5	TIOCA5	TIOCA5
	TGRB_5		TIOCB5

Note: In PWM mode 2, PWM output is not possible for the TGR register in which the cycle is set.

### (3) Example of PWM Mode Setting Procedure

Figure 9.21 shows an example of the PWM mode setting procedure.

**Figure 9.21 Example of PWM Mode Setting Procedure**

### (4) Examples of PWM Mode Operation

Figure 9.22 shows an example of PWM mode 1 operation.

In this example, TGRA compare match is set as the TCNT clearing source, 0 is set for the TGRA initial output value and output value, and 1 is set as the TGRB output value.

In this case, the value set in TGRA is used as the cycle, and the value set in TGRB register as the duty cycle.

**Figure 9.22 Example of PWM Mode Operation (1)**

Figure 9.23 shows an example of PWM mode 2 operation.

In this example, synchronous operation is designated for channels 0 and 1, TGRB\_1 compare match is set as the TCNT clearing source, and 0 is set for the initial output value and 1 for the output value of the other TGR registers (TGRA\_0 to TGRD\_0, TGRA\_1), to output a 5-phase PWM waveform.

In this case, the value set in TGRB\_1 is used as the cycle, and the values set in the other TGRs as the duty cycle.

**Figure 9.23 Example of PWM Mode Operation (2)**

Figure 9.24 shows examples of PWM waveform output with 0% duty cycle and 100% duty cycle in PWM mode.

**Figure 9.24 Example of PWM Mode Operation (3)**

### 9.4.6 Phase Counting Mode

In phase counting mode, the phase difference between two external clock inputs is detected and TCNT is incremented/decremented accordingly. This mode can be set for channels 1, 2, 4, and 5.

When phase counting mode is set, an external clock is selected as the counter input clock and TCNT operates as an up/down-counter regardless of the setting of bits TPSC2 to TPSC0 and bits CKEG1 and CKEG0 in TCR. However, the functions of bits CCLR1 and CCLR0 in TCR, and of TIOR, TIER, and TGR are valid, and input capture/compare match and interrupt functions can be used.

This can be used for two-phase encoder pulse input.

When overflow occurs while TCNT is counting up, the TCFV flag in TSR is set; when underflow occurs while TCNT is counting down, the TCFU flag is set.

The TCFD bit in TSR is the count direction flag. Reading the TCFD flag provides an indication of whether TCNT is counting up or down.

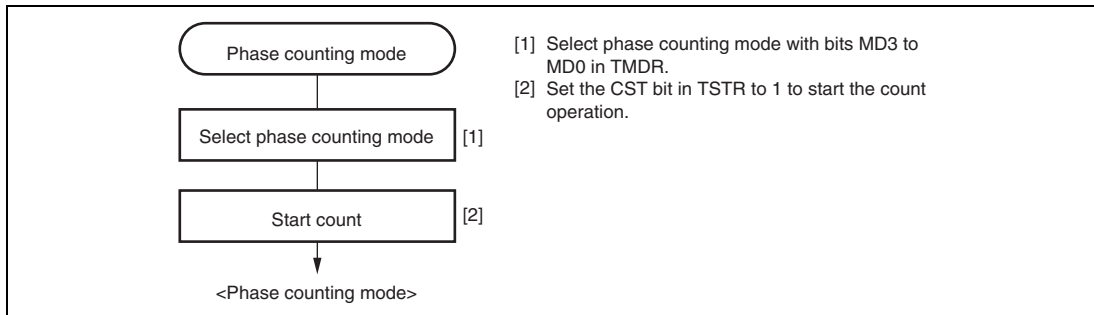

Table 9.34 shows the correspondence between external clock pins and channels.

**Table 9.34 Clock Input Pins in Phase Counting Mode**

Channels	External Clock Pins	
	A-Phase	B-Phase
When channel 1 or 5 is set to phase counting mode	TCLKA	TCLKB
When channel 2 or 4 is set to phase counting mode	TCLKC	TCLKD

### (1) Example of Phase Counting Mode Setting Procedure

Figure 9.25 shows an example of the phase counting mode setting procedure.

**Figure 9.25 Example of Phase Counting Mode Setting Procedure**

## (2) Examples of Phase Counting Mode Operation

In phase counting mode, TCNT counts up or down according to the phase difference between two external clocks. There are four modes, according to the count conditions.

### (a) Phase counting mode 1

Figure 9.26 shows an example of phase counting mode 1 operation, and table 9.35 summarizes the TCNT up/down-count conditions.

Figure 9.26 Example of Phase Counting Mode 1 Operation

Table 9.35 Up/Down-Count Conditions in Phase Counting Mode 1

### (3) Phase Counting Mode Application Example

Figure 9.30 shows an example in which phase counting mode is designated for channel 1, and channel 1 is coupled with channel 0 to input servo motor 2-phase encoder pulses in order to detect the position or speed.

Channel 1 is set to phase counting mode 1, and the encoder pulse A-phase and B-phase are input to TCLKA and TCLKB.

Channel 0 operates with TCNT counter clearing by TGRC\_0 compare match; TGRA\_0 and TGRC\_0 are used for the compare match function and are set with the speed control cycle and position control cycle. TGRB\_0 is used for input capture, with TGRB\_0 and TGRD\_0 operating in buffer mode. The channel 1 counter input clock is designated as the TGRB\_0 input capture source, and the pulse width of 2-phase encoder 4-multiplication pulses is detected.

TGRA\_1 and TGRB\_1 for channel 1 are designated for input capture, channel 0 TGRA\_0 and TGRC\_0 compare matches are selected as the input capture source, and the up/down-counter values for the control cycles are stored.

This procedure enables accurate position/speed detection to be achieved.

**Figure 9.30 Phase Counting Mode Application Example**

## 9.5 Interrupt Sources

There are three kinds of TPU interrupt sources: TGR input capture/compare match, TCNT overflow, and TCNT underflow. Each interrupt source has its own status flag and enable/disable bit, allowing generation of interrupt request signals to be enabled or disabled individually.

When an interrupt request is generated, the corresponding status flag in TSR is set to 1. If the corresponding enable/disable bit in TIER is set to 1 at this time, an interrupt is requested. The interrupt request is cleared by clearing the status flag to 0.

Relative channel priority levels can be changed by the interrupt controller, but the priority within a channel is fixed. For details, see section 5, Interrupt Controller.

Table 9.39 lists the TPU interrupt sources.

**Table 9.39 TPU Interrupts**

Channel	Name	Interrupt Source	Interrupt Flag	DMAC Activation
0	TGI0A	TGRA_0 input capture/compare match	TGFA_0	Possible
	TGI0B	TGRB_0 input capture/compare match	TGFB_0	Not possible
	TGI0C	TGRC_0 input capture/compare match	TGFC_0	Not possible
	TGI0D	TGRD_0 input capture/compare match	TGFD_0	Not possible
	TCI0V	TCNT_0 overflow	TCFV_0	Not possible
1	TGI1A	TGRA_1 input capture/compare match	TGFA_1	Possible
	TGI1B	TGRB_1 input capture/compare match	TGFB_1	Not possible
	TCI1V	TCNT_1 overflow	TCFV_1	Not possible
	TCI1U	TCNT_1 underflow	TCFU_1	Not possible
2	TGI2A	TGRA_2 input capture/compare match	TGFA_2	Possible
	TGI2B	TGRB_2 input capture/compare match	TGFB_2	Not possible
	TCI2V	TCNT_2 overflow	TCFV_2	Not possible
	TCI2U	TCNT_2 underflow	TCFU_2	Not possible

Channel	Name	Interrupt Source	Interrupt Flag	DMAC Activation
3	TGI3A	TGRA_3 input capture/compare match	TGFA_3	Possible
	TGI3B	TGRB_3 input capture/compare match	TGFB_3	Not possible
	TGI3C	TGRC_3 input capture/compare match	TGFC_3	Not possible
	TGI3D	TGRD_3 input capture/compare match	TGFD_3	Not possible
	TCI3V	TCNT_3 overflow	TCFV_3	Not possible
4	TGI4A*	TGRA_4 input capture/compare match	TGFA_4	Possible
	TGI4B*	TGRB_4 input capture/compare match	TGFB_4	Not possible
	TCI4V	TCNT_4 overflow	TCFV_4	Not possible
	TCI4U	TCNT_4 underflow	TCFU_4	Not possible
5	TGI5A*	TGRA_5 input capture/compare match	TGFA_5	Possible
	TGI5B*	TGRB_5 input capture/compare match	TGFB_5	Not possible
	TCI5V	TCNT_5 overflow	TCFV_5	Not possible
	TCI5U	TCNT_5 underflow	TCFU_5	Not possible
6	TGI6A	TGRA_0 input capture/compare match	TGFA_0	Possible
	TGI6B	TGRB_0 input capture/compare match	TGFB_0	Not possible
	TGI6C	TGRC_0 input capture/compare match	TGFC_0	Not possible
	TGI6D	TGRD_0 input capture/compare match	TGFD_0	Not possible
	TCI6V	TCNT_0 overflow	TCFV_0	Not possible
7	TGI7A	TGRA_1 input capture/compare match	TGFA_1	Possible
	TGI7B	TGRB_1 input capture/compare match	TGFB_1	Not possible
	TCI7V	TCNT_1 overflow	TCFV_1	Not possible
	TCI7U	TCNT_1 underflow	TCFU_1	Not possible
8	TGI8A	TGRA_2 input capture/compare match	TGFA_2	Possible
	TGI8B	TGRB_2 input capture/compare match	TGFB_2	Not possible
	TCI8V	TCNT_2 overflow	TCFV_2	Not possible
	TCI8U	TCNT_2 underflow	TCFU_2	Not possible
9	TGI9A	TGRA_3 input capture/compare match	TGFA_3	Possible
	TGI9B	TGRB_3 input capture/compare match	TGFB_3	Not possible
	TGI9C	TGRC_3 input capture/compare match	TGFC_3	Not possible
	TGI9D	TGRD_3 input capture/compare match	TGFD_3	Not possible
	TCI9V	TCNT_3 overflow	TCFV_3	Not possible

Channel	Name	Interrupt Source	Interrupt Flag	DMAC Activation
10	TGI10A	TGRA_4 input capture/compare match	TGFA_4	Possible
	TGI10B	TGRB_4 input capture/compare match	TGFB_4	Not possible
	TCI10V	TCNT_4 overflow	TCFV_4	Not possible
	TCI10U	TCNT_4 underflow	TCFU_4	Not possible
11	TGI11A	TGRA_5 input capture/compare match	TGFA_5	Possible
	TGI11B	TGRB_5 input capture/compare match	TGFB_5	Not possible
	TCI11V	TCNT_5 overflow	TCFV_5	Not possible
	TCI11U	TCNT_5 underflow	TCFU_5	Not possible

Note: 1. This table shows the initial state immediately after a reset. The relative channel priority levels can be changed by the interrupt controller.  
 2. The H8SX/1527R does not have the input capture function for channels 4 and 5.

### (1) Input Capture/Compare Match Interrupt

An interrupt is requested if the TGIE bit in TIER is set to 1 when the TGF flag in TSR is set to 1 by the occurrence of a TGR input capture/compare match on a channel. The interrupt request is cleared by clearing the TGF flag to 0. The TPU has 16 input capture/compare match interrupts, four each for channels 0 and 3, and two each for channels 1, 2, 4, and 5.

### (2) Overflow Interrupt

An interrupt is requested if the TCIEV bit in TIER is set to 1 when the TCFV flag in TSR is set to 1 by the occurrence of a TCNT overflow on a channel. The interrupt request is cleared by clearing the TCFV flag to 0. The TPU has six overflow interrupts, one for each channel.

### (3) Underflow Interrupt

An interrupt is requested if the TCIEU bit in TIER is set to 1 when the TCFU flag in TSR is set to 1 by the occurrence of a TCNT underflow on a channel. The interrupt request is cleared by clearing the TCFU flag to 0. The TPU has four underflow interrupts, one each for channels 1, 2, 4, and 5.

## 9.6 DMAC Activation

The DMAC can be activated by the TGR input capture/compare match interrupt for a channel. For details, see section 7, DMA Controller (DMAC).

A total of six TPU input capture/compare match interrupts can be used as DMAC activation sources, one for each channel.

## 9.7 A/D Converter Activation

The TGRA input capture/compare match for each channel of unit 0 can activate the A/D converter (this function is not available for unit 1).

If the TTGE bit in TIER is set to 1 when the TGFA flag in TSR is set to 1 by the occurrence of a TGRA input capture/compare match on a particular channel, a request to start A/D conversion is sent to the A/D converter. If the TPU conversion start trigger has been selected on the A/D converter side at this time, A/D conversion is started.

In the TPU, a total of six TGRA input capture/compare match interrupts can be used as A/D converter conversion start sources, one for each channel.

The A/D converter cannot be activated by unit 1.

## 9.8 Operation Timing

### 9.8.1 Input/Output Timing

#### (1) TCNT Count Timing

Figure 9.31 shows TCNT count timing in internal clock operation, and figure 9.32 shows TCNT count timing in external clock operation.

**Figure 9.31 Count Timing in Internal Clock Operation**

**Figure 9.32 Count Timing in External Clock Operation**

## (2) Output Compare Output Timing

A compare match signal is generated in the final state in which TCNT and TGR match (the point at which the count value matched by TCNT is updated). When a compare match signal is generated, the output value set in TIOR is output at the output compare output pin (TIOC pin). After a match between TCNT and TGR, the compare match signal is not generated until the TCNT input clock is generated.

Figure 9.33 shows output compare output timing.

**Figure 9.33 Output Compare Output Timing**

## (3) Input Capture Signal Timing

Figure 9.34 shows input capture signal timing.

**Figure 9.34 Input Capture Input Signal Timing**

#### (4) Timing for Counter Clearing by Compare Match/Input Capture

Figure 9.35 shows the timing when counter clearing by compare match occurrence is specified, and figure 9.36 shows the timing when counter clearing by input capture occurrence is specified.

**Figure 9.35 Counter Clear Timing (Compare Match)**

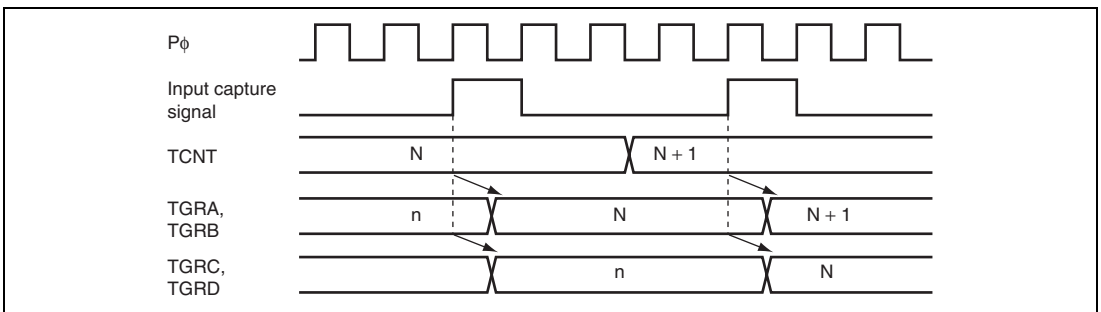

**Figure 9.36 Counter Clear Timing (Input Capture)**

## (5) Buffer Operation Timing

Figures 9.37 and 9.38 show the timings in buffer operation.

**Figure 9.37 Buffer Operation Timing (Compare Match)**

**Figure 9.38 Buffer Operation Timing (Input Capture)**

## 9.8.2 Interrupt Signal Timing

### (1) TGF Flag Setting Timing in Case of Compare Match

Figure 9.39 shows the timing for setting of the TGF flag in TSR by compare match occurrence, and the TGI interrupt request signal timing.

**Figure 9.39 TGI Interrupt Timing (Compare Match)**

### (2) TGF Flag Setting Timing in Case of Input Capture

Figure 9.40 shows the timing for setting of the TGF flag in TSR by input capture occurrence, and the TGI interrupt request signal timing.

**Figure 9.40 TGI Interrupt Timing (Input Capture)**

### (3) TCFV Flag/TCFU Flag Setting Timing

Figure 9.41 shows the timing for setting of the TCFV flag in TSR by overflow occurrence, and the TCIV interrupt request signal timing.

Figure 9.42 shows the timing for setting of the TCFU flag in TSR by underflow occurrence, and the TCIU interrupt request signal timing.

**Figure 9.41 TCIV Interrupt Setting Timing**

**Figure 9.42 TCIU Interrupt Setting Timing**

#### (4) Status Flag Clearing Timing

After a status flag is read as 1 by the CPU, it is cleared by writing 0 to it. When the DMAC is activated, the flag is cleared automatically. Figure 9.43 shows the timing for status flag clearing by the CPU, and figure 9.44 shows the timing for status flag clearing by the DMAC.

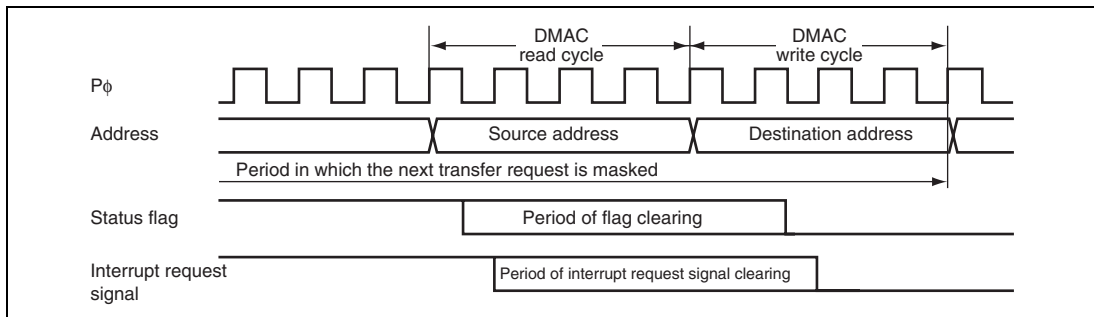

**Figure 9.43 Timing for Status Flag Clearing by CPU**

The status flag and interrupt request signal are cleared in synchronization with  $P\phi$  after the DMAC transfer has started, as shown in figure 9.44. If conflict occurs for clearing the status flag and interrupt request signal due to activation of multiple DMAC transfers, it will take up to five clock cycles ( $P\phi$ ) for clearing them, as shown in figure 9.45. The next transfer request is masked for a longer period of either a period until the current transfer ends or a period for five clock cycles ( $P\phi$ ) from the beginning of the transfer.

**Figure 9.44 Timing for Status Flag Clearing by DMAC Activation (1)**

**Figure 9.45 Timing for Status Flag Clearing by DMAC Activation (2)**

## 9.9 Usage Notes

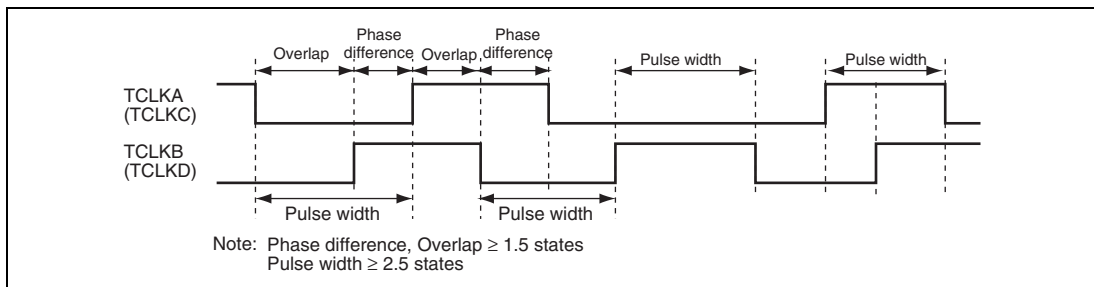

### 9.9.1 Module Stop Mode Setting

Operation of the TPU can be disabled or enabled using the module stop control register. The initial setting is for operation of the TPU to be halted. Register access is enabled by clearing module stop mode. For details, refer to section 19, Power-Down Modes.

### 9.9.2 Input Clock Restrictions

The input clock pulse width must be at least 1.5 states in the case of single-edge detection, and at least 2.5 states in the case of both-edge detection. The TPU will not operate properly with a narrower pulse width.

In phase counting mode, the phase difference and overlap between the two input clocks must be at least 1.5 states, and the pulse width must be at least 2.5 states. Figure 9.46 shows the input clock conditions in phase counting mode.

**Figure 9.46 Phase Difference, Overlap, and Pulse Width in Phase Counting Mode**

### 9.9.3 Caution on Cycle Setting

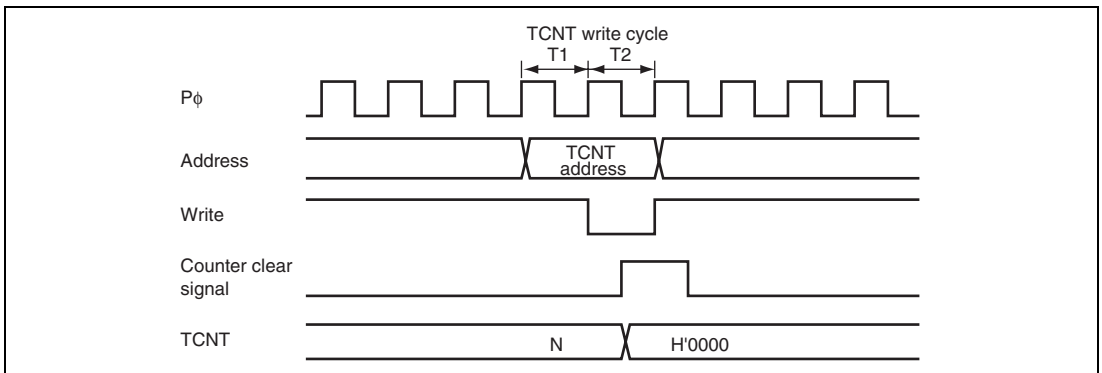

When counter clearing by compare match is set, TCNT is cleared in the final state in which it matches the TGR value (the point at which the count value matched by TCNT is updated). Consequently, the actual counter frequency is given by the following formula:

$$f = \frac{P\phi}{(N + 1)}$$

- f: Counter frequency
- P $\phi$ : Operating frequency
- N: TGR set value

### 9.9.4 Conflict between TCNT Write and Clear Operations

If the counter clearing signal is generated in the T2 state of a TCNT write cycle, TCNT clearing takes precedence and the TCNT write is not performed. Figure 9.47 shows the timing in this case.

**Figure 9.47 Conflict between TCNT Write and Clear Operations**

### 9.9.5 Conflict between TCNT Write and Increment Operations

If incrementing occurs in the T2 state of a TCNT write cycle, the TCNT write takes precedence and TCNT is not incremented. Figure 9.48 shows the timing in this case.

**Figure 9.48 Conflict between TCNT Write and Increment Operations**

### 9.9.6 Conflict between TGR Write and Compare Match

If a compare match occurs in the T2 state of a TGR write cycle, the TGR write takes precedence and the compare match signal is disabled. A compare match also does not occur when the same value as before is written.

Figure 9.49 shows the timing in this case.

**Figure 9.49 Conflict between TGR Write and Compare Match**

### 9.9.7 Conflict between Buffer Register Write and Compare Match

If a compare match occurs in the T2 state of a TGR write cycle, the data transferred to TGR by the buffer operation will be the write data.

Figure 9.50 shows the timing in this case.

**Figure 9.50 Conflict between Buffer Register Write and Compare Match**

### 9.9.8 Conflict between TGR Read and Input Capture

If the input capture signal is generated in the T1 state of a TGR read cycle, the data that is read will be the data after input capture transfer.

Figure 9.51 shows the timing in this case.

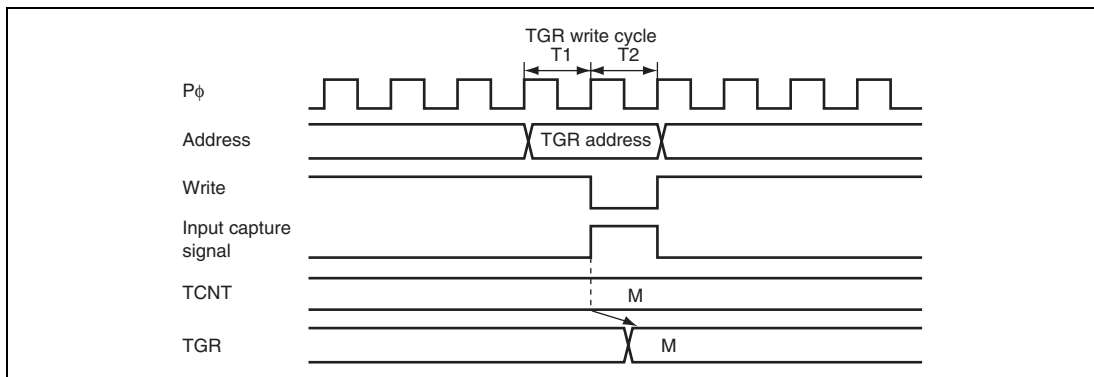

**Figure 9.51 Conflict between TGR Read and Input Capture**

### 9.9.9 Conflict between TGR Write and Input Capture

If the input capture signal is generated in the T2 state of a TGR write cycle, the input capture operation takes precedence and the write to TGR is not performed.

Figure 9.52 shows the timing in this case.

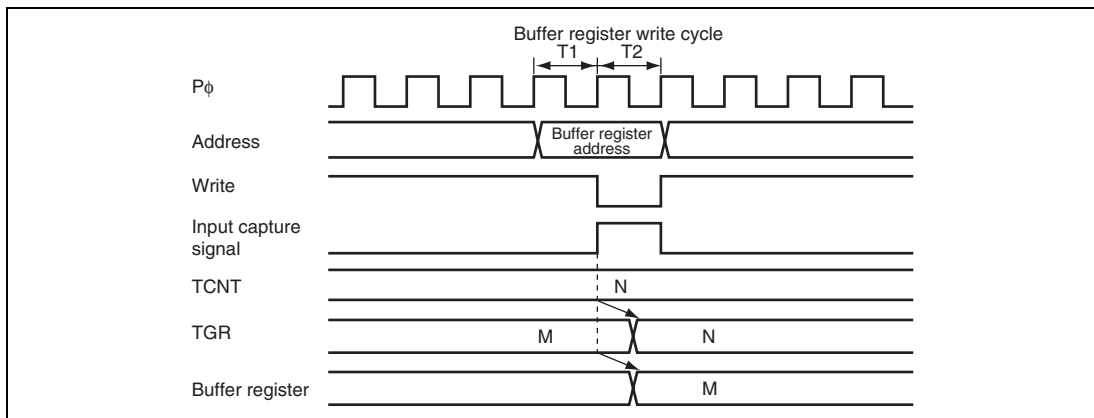

**Figure 9.52 Conflict between TGR Write and Input Capture**

### 9.9.10 Conflict between Buffer Register Write and Input Capture

If the input capture signal is generated in the T2 state of a buffer register write cycle, the buffer operation takes precedence and the write to the buffer register is not performed.

Figure 9.53 shows the timing in this case.

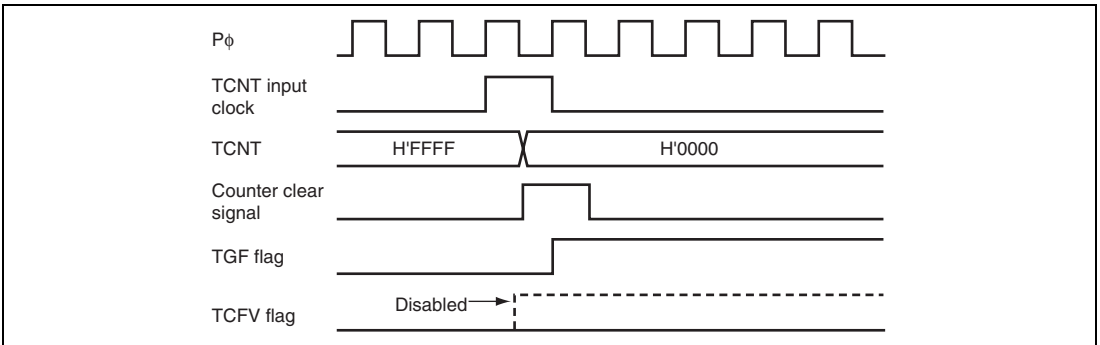

**Figure 9.53 Conflict between Buffer Register Write and Input Capture**

### 9.9.11 Conflict between Overflow/Underflow and Counter Clearing

If overflow/underflow and counter clearing occur simultaneously, the TCFV/TCFU flag in TSR is not set and TCNT clearing takes precedence.

Figure 9.54 shows the operation timing when a TGR compare match is specified as the clearing source, and H'FFFF is set in TGR.

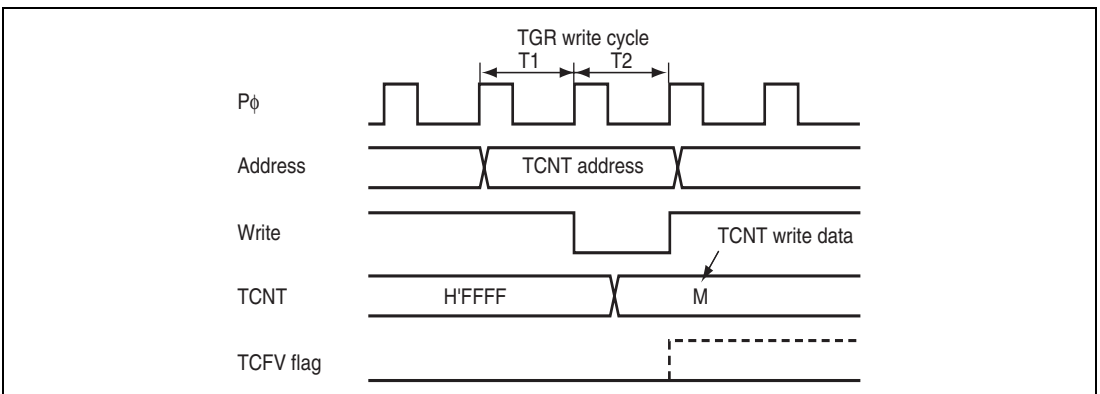

**Figure 9.54 Conflict between Overflow and Counter Clearing**

### 9.9.12 Conflict between TCNT Write and Overflow/Underflow

If an overflow/underflow occurs due to increment/decrement in the T2 state of a TCNT write cycle, the TCNT write takes precedence and the TCFV/TCFU flag in TSR is not set.

Figure 9.55 shows the operation timing when there is conflict between TCNT write and overflow.

**Figure 9.55 Conflict between TCNT Write and Overflow**

### 9.9.13 Multiplexing of I/O Pins

In this LSI, the TCLKA input pin is multiplexed with the TIOCC0 I/O pin, the TCLKB input pin with the TIOCD0 I/O pin, the TCLKC input pin with the TIOCB1 I/O pin, and the TCLKD input pin with the TIOCB2 I/O pin. When an external clock is input, compare match output should not be performed from a multiplexed pin.

### 9.9.14 Interrupts and Module Stop Mode

If module stop mode is entered when an interrupt has been requested, it will not be possible to clear the CPU interrupt source or the DMAC activation source. Interrupts should therefore be disabled before entering module stop mode.

## Section 10 Programmable Pulse Generator (PPG)

The programmable pulse generator (PPG) provides pulse outputs by using the 16-bit timer pulse unit (TPU) as a time base. The PPG pulse outputs are divided into 4-bit groups (groups 3 and 2) that can operate both simultaneously and independently. Figure 10.1 shows a block diagram of the PPG.

### 10.1 Features

- 8-bit output data
- Two output groups
- Selectable output trigger signals
- Non-overlapping mode
- Can operate together with the DMA controller (DMAC)
- Inverted output can be set
- Module stop mode can be set

Figure 10.1 Block Diagram of PPG

## 10.2 Input/Output Pins

Table 10.1 shows the PPG pin configuration.

**Table 10.1 Pin Configuration**

<b>Pin Name</b>	<b>I/O</b>	<b>Function</b>
PO15	Output	Group 3 pulse output
PO14	Output	
PO13	Output	
PO12	Output	Group 2 pulse output
PO11	Output	
PO10	Output	
PO9	Output	
PO8	Output	

## 10.3 Register Descriptions

The PPG has the following registers.

- Next data enable register H (NDERH)
- Next data enable register L (NDERL)
- Output data register H (PODRH)
- Output data register L (PODRL)
- Next data register H (NDRH)
- Next data register L (NDRL)
- PPG output control register (PCR)
- PPG output mode register (PMR)

### 10.3.1 Next Data Enable Registers H, L (NDERH, NDERL)

NDERH and NDERL enable/disable pulse output on a bit-by-bit basis.

- NDERH

Bit	7	6	5	4	3	2	1	0
Bit Name	NDER15	NDER14	NDER13	NDER12	NDER11	NDER10	NDER9	NDER8
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

- NDERL

Bit	7	6	5	4	3	2	1	0
Bit Name	NDER7	NDER6	NDER5	NDER4	NDER3	NDER2	NDER1	NDER0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

## • NDERH

Bit	Bit Name	Initial Value	R/W	Description
7	NDER15	0	R/W	Next Data Enable 15 to 8
6	NDER14	0	R/W	When a bit is set to 1, the value in the corresponding NDRH bit is transferred to the PODRH bit by the selected output trigger. Values are not transferred from NDRH to PODRH for cleared bits.
5	NDER13	0	R/W	
4	NDER12	0	R/W	
3	NDER11	0	R/W	
2	NDER10	0	R/W	
1	NDER9	0	R/W	
0	NDER8	0	R/W	

---

## • NDERL

Bit	Bit Name	Initial Value	R/W	Description
7	NDER7	0	R/W	Next Data Enable 7 to 0
6	NDER6	0	R/W	When a bit is set to 1, the value in the corresponding NDRL bit is transferred to the PODRL bit by the selected output trigger. Values are not transferred from NDRL to PODRL for cleared bits.
5	NDER5	0	R/W	
4	NDER4	0	R/W	
3	NDER3	0	R/W	
2	NDER2	0	R/W	
1	NDER1	0	R/W	
0	NDER0	0	R/W	

---

### 10.3.2 Output Data Registers H, L (PODRH, PODRL)

PODRH and PODRL store output data for use in pulse output. A bit that has been set for pulse output by NDER is read-only and cannot be modified.

- PODRH

Bit	7	6	5	4	3	2	1	0
Bit Name	POD15	POD14	POD13	POD12	POD11	POD10	POD9	POD8
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

- PODRL

Bit	7	6	5	4	3	2	1	0
Bit Name	POD7	POD6	POD5	POD4	POD3	POD2	POD1	POD0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

- PODRH

Bit	Bit Name	Initial Value	R/W	Description
7	POD15	0	R/W	Output Data Register 15 to 8
6	POD14	0	R/W	For bits which have been set to pulse output by NDERH, the output trigger transfers NDRH values to this register during PPG operation. While NDERH is set to 1, the CPU cannot write to this register. While NDERH is cleared, the initial output value of the pulse can be set.
5	POD13	0	R/W	
4	POD12	0	R/W	
3	POD11	0	R/W	
2	POD10	0	R/W	
1	POD9	0	R/W	
0	POD8	0	R/W	

- PODRL

Bit	Bit Name	Initial Value	R/W	Description
7	POD7	0	R/W	Output Data Register 7 to 0
6	POD6	0	R/W	For bits which have been set to pulse output by NDERL, the output trigger transfers NDRL values to this register during PPG operation. While NDERL is set to 1, the CPU cannot write to this register. While NDERL is cleared, the initial output value of the pulse can be set.
5	POD5	0	R/W	
4	POD4	0	R/W	
3	POD3	0	R/W	
2	POD2	0	R/W	
1	POD1	0	R/W	
0	POD0	0	R/W	

### 10.3.3 Next Data Registers H, L (NDRH, NDRL)

NDRH and NDRL store the next data for pulse output. The NDR addresses differ depending on whether pulse output groups have the same output trigger or different output triggers.

- NDRH

Bit	7	6	5	4	3	2	1	0
Bit Name	NDR15	NDR14	NDR13	NDR12	NDR11	NDR10	NDR9	NDR8
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

- NDRL

Bit	7	6	5	4	3	2	1	0
Bit Name	NDR7	NDR6	NDR5	NDR4	NDR3	NDR2	NDR1	NDR0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

- NDRH

If pulse output groups 2 and 3 have the same output trigger, all eight bits are mapped to the same address and can be accessed at one time, as shown below.

Bit	Bit Name	Initial Value	R/W	Description
7	NDR15	0	R/W	Next Data Register 15 to 8
6	NDR14	0	R/W	The register contents are transferred to the corresponding PODRH bits by the output trigger specified with PCR.
5	NDR13	0	R/W	
4	NDR12	0	R/W	
3	NDR11	0	R/W	
2	NDR10	0	R/W	
1	NDR9	0	R/W	
0	NDR8	0	R/W	

If pulse output groups 2 and 3 have different output triggers, the upper four bits and lower four bits are mapped to different addresses as shown below.

Bit	Bit Name	Initial Value	R/W	Description
7	NDR15	0	R/W	Next Data Register 15 to 12
6	NDR14	0	R/W	The register contents are transferred to the corresponding PODRH bits by the output trigger specified with PCR.
5	NDR13	0	R/W	
4	NDR12	0	R/W	
3 to 0	—	All 1	R	

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	All 1	R	Reserved These are read-only bits and cannot be modified.
3	NDR11	0	R/W	Next Data Register 11 to 8
2	NDR10	0	R/W	The register contents are transferred to the corresponding PODRH bits by the output trigger specified with PCR.
1	NDR9	0	R/W	
0	NDR8	0	R/W	

- NDRL

If pulse output groups 0 and 1 have the same output trigger, all eight bits are mapped to the same address and can be accessed at one time, as shown below.

Bit	Bit Name	Initial Value	R/W	Description
7	NDR7	0	R/W	Next Data Register 7 to 0
6	NDR6	0	R/W	The register contents are transferred to the corresponding PODRL bits by the output trigger specified with PCR.
5	NDR5	0	R/W	
4	NDR4	0	R/W	
3	NDR3	0	R/W	
2	NDR2	0	R/W	
1	NDR1	0	R/W	
0	NDR0	0	R/W	

If pulse output groups 0 and 1 have different output triggers, the upper four bits and lower four bits are mapped to different addresses as shown below.

Bit	Bit Name	Initial Value	R/W	Description
7	NDR7	0	R/W	Next Data Register 7 to 4
6	NDR6	0	R/W	The register contents are transferred to the corresponding PODRL bits by the output trigger specified with PCR.
5	NDR5	0	R/W	
4	NDR4	0	R/W	
3 to 0	—	All 1	R	

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	All 1	R	Reserved These are read-only bits and cannot be modified.
3	NDR3	0	R/W	Next Data Register 3 to 0
2	NDR2	0	R/W	The register contents are transferred to the corresponding PODRL bits by the output trigger specified with PCR.
1	NDR1	0	R/W	
0	NDR0	0	R/W	

### 10.3.4 PPG Output Control Register (PCR)

PCR selects output trigger signals on a group-by-group basis. For details on output trigger selection, refer to section 10.3.5, PPG Output Mode Register (PMR).

Bit	7	6	5	4	3	2	1	0
Bit Name	G3CMS1	G3CMS0	G2CMS1	G2CMS0	—	—	—	—
Initial Value	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	G3CMS1	1	R/W	Group 3 Compare Match Select 1 and 0
6	G3CMS0	1	R/W	These bits select output trigger of pulse output group 3. 00: Compare match in TPU channel 0 01: Compare match in TPU channel 1 10: Compare match in TPU channel 2 11: Compare match in TPU channel 3
5	G2CMS1	1	R/W	Group 2 Compare Match Select 1 and 0
4	G2CMS0	1	R/W	These bits select output trigger of pulse output group 2. 00: Compare match in TPU channel 0 01: Compare match in TPU channel 1 10: Compare match in TPU channel 2 11: Compare match in TPU channel 3
3 to 0	—	All 1	R/W	Reserved These bits are always read as 1. The write value should always be 1.

### 10.3.5 PPG Output Mode Register (PMR)

PMR selects the pulse output mode of the PPG for each group. If inverted output is selected, a low-level pulse is output when PODRH is 1 and a high-level pulse is output when PODRH is 0. If non-overlapping operation is selected, PPG updates its output values at compare match A or B of the TPU that becomes the output trigger. For details, refer to section 10.4.4, Non-Overlapping Pulse Output.

Bit	7	6	5	4	3	2	1	0
Bit Name	G3INV	G2INV	—	—	G3NOV	G2NOV	—	—
Initial Value	1	1	1	1	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

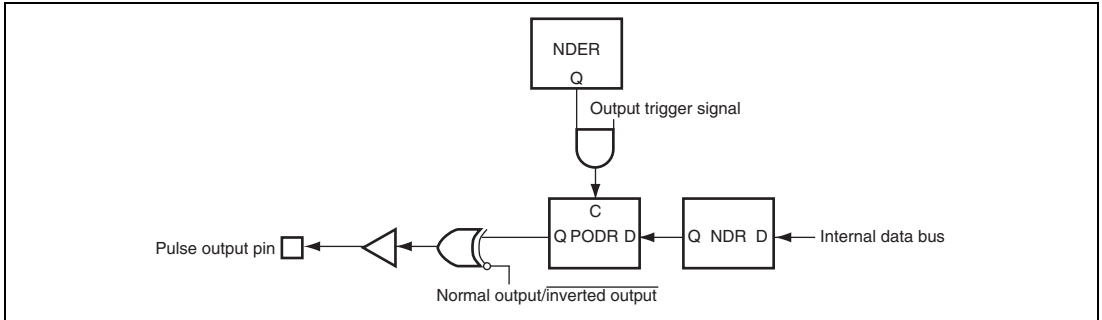

Bit	Bit Name	Initial Value	R/W	Description
7	G3INV	1	R/W	Group 3 Inversion Selects direct output or inverted output for pulse output group 3. 0: Inverted output 1: Direct output
6	G2INV	1	R/W	Group 2 Inversion Selects direct output or inverted output for pulse output group 2. 0: Inverted output 1: Direct output
5, 4	—	All 1	R/W	Reserved These bits are always read as 1. The write value should always be 1.

Bit	Bit Name	Initial Value	R/W	Description
3	G3NOV	0	R/W	<p>Group 3 Non-Overlap</p> <p>Selects normal or non-overlapping operation for pulse output group 3.</p> <p>0: Normal operation (output values updated at compare match A in the selected TPU channel)</p> <p>1: Non-overlapping operation (output values updated at compare match A or B in the selected TPU channel)</p>
2	G2NOV	0	R/W	<p>Group 2 Non-Overlap</p> <p>Selects normal or non-overlapping operation for pulse output group 2.</p> <p>0: Normal operation (output values updated at compare match A in the selected TPU channel)</p> <p>1: Non-overlapping operation (output values updated at compare match A or B in the selected TPU channel)</p>
1, 0	—	All 0	R/W	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>

## 10.4 Operation

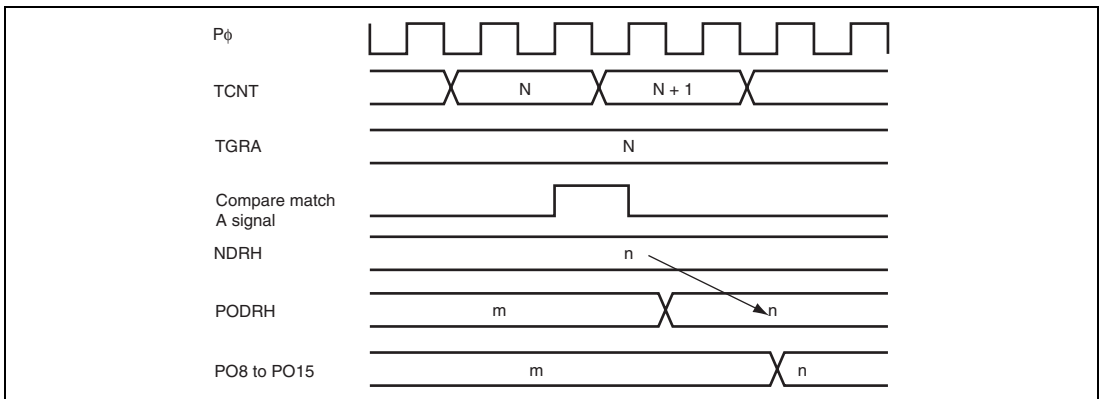

Figure 10.2 shows a schematic diagram of the PPG. PPG pulse output is enabled when the corresponding bits in NDER are set to 1. An initial output value is determined by its corresponding PODR initial setting. When the compare match event specified by PCR occurs, the corresponding NDR bit contents are transferred to PODR to update the output values. Sequential output of data of up to eight bits is possible by writing new output data to NDR before the next compare match.

**Figure 10.2 Schematic Diagram of PPG**

### 10.4.1 Output Timing

If pulse output is enabled, the NDR contents are transferred to PODR and output when the specified compare match event occurs. Figure 10.3 shows the timing of these operations for the case of normal output in groups 2 and 3, triggered by compare match A.

**Figure 10.3 Timing of Transfer and Output of NDR Contents (Example)**

### 10.4.2 Sample Setup Procedure for Normal Pulse Output

Figure 10.4 shows a sample procedure for setting up normal pulse output.

**Figure 10.4 Setup Procedure for Normal Pulse Output (Example)**

### 10.4.3 Example of Normal Pulse Output (Example of 5-Phase Pulse Output)

Figure 10.5 shows an example in which pulse output is used for cyclic 5-phase pulse output.

**Figure 10.5 Normal Pulse Output Example (5-Phase Pulse Output)**

1. Set up TGRA in TPU which is used as the output trigger to be an output compare register. Set a cycle in TGRA so the counter will be cleared by compare match A. Set the TGIEA bit in TIER to 1 to enable the compare match/input capture A (TGIA) interrupt.
2. Write H'F8 to NDRH, and set bits G3CMS1, G3CMS0, G2CMS1, and G2CMS0 in PCR to select compare match in the TPU channel set up in the previous step to be the output trigger. Write output data H'80 in NDRH.
3. The timer counter in the TPU channel starts. When compare match A occurs, the NDRH contents are transferred to PODRH and output. The TGIA interrupt handling routine writes the next output data (H'C0) in NDRH.
4. 5-phase pulse output (one or two phases active at a time) can be obtained subsequently by writing H'40, H'60, H'20, H'30, H'10, H'18, H'08, H'88... at successive TGIA interrupts. If the DMAC is set for activation by the TGIA interrupt, pulse output can be obtained without imposing a load on the CPU.

### 10.4.4 Non-Overlapping Pulse Output

During non-overlapping operation, transfer from NDR to PODR is performed as follows:

- At compare match A, the NDR bits are always transferred to PODR.
- At compare match B, the NDR bits are transferred only if their value is 0. The NDR bits are not transferred if their value is 1.

Figure 10.6 illustrates the non-overlapping pulse output operation.

**Figure 10.6 Non-Overlapping Pulse Output**

Therefore, 0 data can be transferred ahead of 1 data by making compare match B occur before compare match A.

The NDR contents should not be altered during the interval from compare match B to compare match A (the non-overlapping margin).

This can be accomplished by having the TGIA interrupt handling routine write the next data in NDR, or by having the TGIA interrupt activate the DMAC. Note, however, that the next data must be written before the next compare match B occurs.

Figure 10.7 shows the timing of this operation.

**Figure 10.7 Non-Overlapping Operation and NDR Write Timing**

### 10.4.5 Sample Setup Procedure for Non-Overlapping Pulse Output

Figure 10.8 shows a sample procedure for setting up non-overlapping pulse output.

**Figure 10.8 Setup Procedure for Non-Overlapping Pulse Output (Example)**

### 10.4.6 Example of Non-Overlapping Pulse Output (Example of 4-Phase Complementary Non-Overlapping Pulse Output)

Figure 10.9 shows an example in which pulse output is used for 4-phase complementary non-overlapping pulse output.

**Figure 10.9 Non-Overlapping Pulse Output Example (4-Phase Complementary)**

1. Set up the TPU channel to be used as the output trigger channel so that TGRA and TGRB are output compare registers. Set the cycle in TGRB and the non-overlapping margin in TGRA, and set the counter to be cleared by compare match B. Set the TGIEA bit in TIER to 1 to enable the TGIA interrupt.
2. Write H'FF to NDERH, and set bits G3CMS1, G3CMS0, G2CMS1, and G2CMS0 in PCR to select compare match in the TPU channel set up in the previous step to be the output trigger. Set bits G3NOV and G2NOV in PMR to 1 to select non-overlapping pulse output. Write output data H'95 to NDRH.
3. The timer counter in the TPU channel starts. When a compare match with TGRB occurs, outputs change from 1 to 0. When a compare match with TGRA occurs, outputs change from 0 to 1 (the change from 0 to 1 is delayed by the value set in TGRA). The TGIA interrupt handling routine writes the next output data (H'65) to NDRH.
4. 4-phase complementary non-overlapping pulse output can be obtained subsequently by writing H'59, H'56, H'95... at successive TGIA interrupts. If the DMAC is set for activation by a TGIA interrupt, pulse can be output without imposing a load on the CPU.

### 10.4.7 Inverted Pulse Output

If the G3INV and G2INV bits in PMR are cleared to 0, values that are the inverse of the PODR contents can be output.

Figure 10.10 shows the outputs when the G3INV and G2INV bits are cleared to 0, in addition to the settings of figure 10.9.

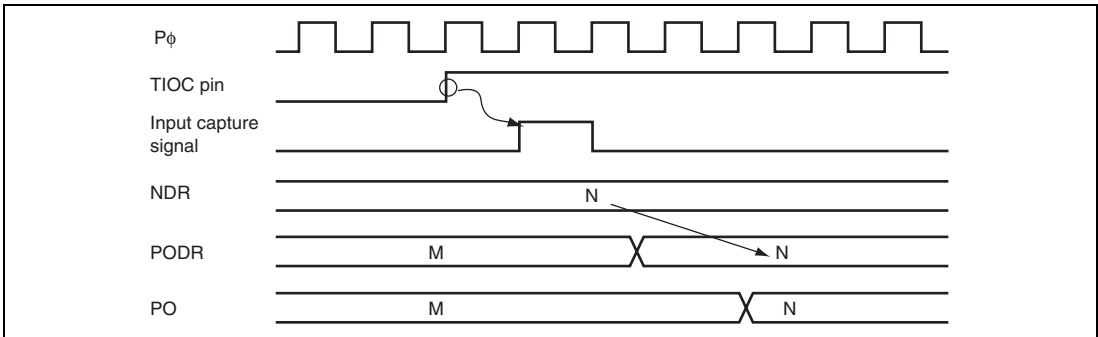

**Figure 10.10 Inverted Pulse Output (Example)**

## 10.4.8 Pulse Output Triggered by Input Capture

Pulse output can be triggered by TPU input capture as well as by compare match. If TGRA functions as an input capture register in the TPU channel selected by PCR, pulse output will be triggered by the input capture signal.

Figure 10.11 shows the timing of this output.

**Figure 10.11 Pulse Output Triggered by Input Capture (Example)**

## 10.5 Usage Notes

### 10.5.1 Module Stop Mode Setting

PPG operation can be disabled or enabled using the module stop control register. The initial value is for PPG operation to be halted. Register access is enabled by clearing module stop mode. For details, refer to section 19, Power-Down Modes.

### 10.5.2 Operation of Pulse Output Pins

Pins PO0 to PO8 are also used for other peripheral functions such as the TPU. When output by another peripheral function is enabled, the corresponding pins cannot be used for pulse output. Note, however, that data transfer from NDR bits to PODR bits takes place, regardless of the usage of the pins.

Pin functions should be changed only under conditions in which the output trigger event will not occur.

## Section 11 Watchdog Timer (WDT)

The watchdog timer (WDT) is an 8-bit timer that outputs an internal reset signal if a system crash prevents the CPU from writing to the timer counter, thus allowing it to overflow.

When this watchdog function is not needed, the WDT can be used as an interval timer. In interval timer operation, an interval timer interrupt is generated each time the counter overflows.

Figure 11.1 shows a block diagram of the WDT.

### 11.1 Features

- Selectable from eight counter input clocks
- Switchable between watchdog timer mode and interval timer mode
  - In watchdog timer mode
    - If the counter overflows, this LSI can be initialized internally.
  - In interval timer mode
    - If the counter overflows, the WDT generates an interval timer interrupt (WOVI).

**Figure 11.1 Block Diagram of WDT**

## 11.2 Register Descriptions

The WDT has the following three registers. To prevent accidental overwriting, TCSR, TCNT, and RSTCSR have to be written to in a method different from normal registers. For details, see section 11.5.1, Notes on Register Access.

- Timer counter (TCNT)
- Timer control/status register (TCSR)
- Reset control/status register (RSTCSR)

### 11.2.1 Timer Counter (TCNT)

TCNT is an 8-bit readable/writable up-counter. TCNT is initialized to H'00 when the TME bit in TCSR is cleared to 0.

Bit	7	6	5	4	3	2	1	0
Bit Name								
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

## 11.2.2 Timer Control/Status Register (TCSR)

TCSR selects the clock source to be input to TCNT, and the timer mode.

Bit	7	6	5	4	3	2	1	0
Bit Name	OVF	WT/ $\overline{\text{IT}}$	TME	—	—	CKS2	CKS1	CKS0
Initial Value	0	0	0	1	1	0	0	0
R/W	R/(W)*	R/W	R/W	R	R	R/W	R/W	R/W

Note: \* Only 0 can be written to this bit, to clear the flag.

Bit	Bit Name	Initial Value	R/W	Description
7	OVF	0	R/(W)*	<p>Overflow Flag</p> <p>Indicates that TCNT has overflowed in interval timer mode. Only 0 can be written to this bit, to clear the flag.</p> <p>[Setting condition]</p> <p>When TCNT overflows in interval timer mode (changes from H'FF to H'00)</p> <p>When internal reset request generation is selected in watchdog timer mode, OVF is cleared automatically by the internal reset.</p> <p>[Clearing condition]</p> <p>Cleared by reading TCSR when OVF = 1, then writing 0 to OVF</p> <p>(When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</p>
6	WT/ $\overline{\text{IT}}$	0	R/W	<p>Timer Mode Select</p> <p>Selects whether the WDT is used as a watchdog timer or interval timer.</p> <p>0: Interval timer mode</p> <p>When TCNT overflows, an interval timer interrupt (WOVI) is requested.</p> <p>1: Watchdog timer mode</p> <p>When TCNT overflows while RSTE = 1, this LSI is initialized initially.</p>

Bit	Bit Name	Initial Value	R/W	Description
5	TME	0	R/W	Timer Enable When this bit is set to 1, TCNT starts counting. When this bit is cleared, TCNT stops counting and is initialized to H'00.
4, 3	—	All 1	R	Reserved These are read-only bits and cannot be modified.
2	CKS2	0	R/W	Clock Select 2 to 0
1	CKS1	0	R/W	Select the clock source to be input to TCNT. The overflow cycle for $P\phi = 20$ MHz is indicated in parentheses.
0	CKS0	0	R/W	000: Clock $P\phi/2$ (cycle: 25.6 $\mu$ s) 001: Clock $P\phi/64$ (cycle: 819.2 $\mu$ s) 010: Clock $P\phi/128$ (cycle: 1.6 ms) 011: Clock $P\phi/512$ (cycle: 6.6 ms) 100: Clock $P\phi/2048$ (cycle: 26.2 ms) 101: Clock $P\phi/8192$ (cycle: 104.9 ms) 110: Clock $P\phi/32768$ (cycle: 419.4 ms) 111: Clock $P\phi/131072$ (cycle: 1.68 s)

Note: \* Only 0 can be written to this bit, to clear the flag.

### 11.2.3 Reset Control/Status Register (RSTCSR)

RSTCSR controls the generation of the internal reset signal when TCNT overflows, and selects the type of internal reset signal. RSTCSR is initialized to H'1F by a reset signal from the  $\overline{\text{RES}}$  pin, but not by the WDT internal reset signal caused by WDT overflows.

Bit	7	6	5	4	3	2	1	0
Bit Name	WOVF	RSTE	—	—	—	—	—	—
Initial Value	0	0	0	1	1	1	1	1
R/W	R/(W)*	R/W	R/W	R	R	R	R	R

Note: \* Only 0 can be written to this bit, to clear the flag.

Bit	Bit Name	Initial Value	R/W	Description
7	WOVF	0	R/(W)*	<p>Watchdog Timer Overflow Flag</p> <p>This bit is set when TCNT overflows in watchdog timer mode. This bit cannot be set in interval timer mode, and only 0 can be written.</p> <p>[Setting condition]</p> <p>When TCNT overflows (changed from H'FF to H'00) in watchdog timer mode</p> <p>[Clearing condition]</p> <p>Reading RSTCSR when WOVF = 1, and then writing 0 to WOVF</p>
6	RSTE	0	R/W	<p>Reset Enable</p> <p>Specifies whether or not this LSI is internally reset if TCNT overflows during watchdog timer operation.</p> <p>0: LSI is not reset even if TCNT overflows (Though this LSI is not reset, TCNT and TCSR in WDT are reset)</p> <p>1: LSI is reset if TCNT overflows</p>
5	—	0	R/W	<p>Reserved</p> <p>This bit is always read as 0. The write value should always be 0.</p>
4 to 0	—	All 1	R	<p>Reserved</p> <p>These are read-only bits and cannot be modified.</p>

Note: \* Only 0 can be written to this bit, to clear the flag.

## 11.3 Operation

### 11.3.1 Watchdog Timer Mode

To use the WDT in watchdog timer mode, set both the  $\overline{WT/IT}$  and TME bits in TCSR to 1.

When TCNT overflows in watchdog timer mode, the WOVF bit in RSTCSR is set to 1.

When the watchdog timer mode is selected and the RSTE bit in RSTCSR is set to 1, if TCNT overflows without being rewritten because of a system crash or other error, this LSI is initialized internally. This ensures that TCNT does not overflow while the system is operating normally. Software must prevent TCNT overflows by rewriting the TCNT value (normally H'00 is written) before overflow occurs.

If a reset caused by a signal input to the  $\overline{RES}$  pin occurs at the same time as a reset caused by a WDT overflow (TCNT has overflowed), the  $\overline{RES}$  pin reset has priority and the WOVF bit in RSTCSR is cleared to 0.

The internal reset signal is output for 519 cycles of  $P\phi$ .

When  $RSTE = 1$ , a signal to initialize this LSI internally is generated. Since this signal initializes the system clock control register (SCKCR), the multiplication ratio of  $P\phi$  clock is also initialized.

When  $RSTE = 0$ , the signal is not generated, meaning that the SCKCR value and multiplication ratio of  $P\phi$  clock remain unchanged.

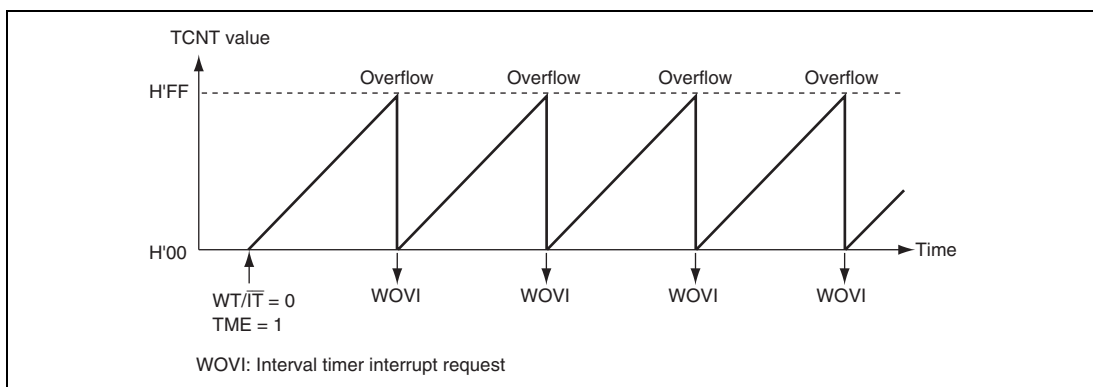

Figure 11.2 Operation in Watchdog Timer Mode

### 11.3.2 Interval Timer Mode

To use the WDT as an interval timer, set the  $\overline{WT/IT}$  bit to 0 and the TME bit to 1 in TCSR.

When the WDT is used as an interval timer, an interval timer interrupt (WOVI) is generated each time the TCNT overflows. Therefore, an interrupt can be generated at intervals.

When the TCNT overflows in interval timer mode, an interval timer interrupt (WOVI) is requested at the same time the OVF bit in the TCSR is set to 1.

**Figure 11.3 Operation in Interval Timer Mode**

### 11.4 Interrupt Source

During interval timer mode operation, an overflow generates an interval timer interrupt (WOVI). The interval timer interrupt is requested whenever the OVF flag is set to 1 in TCSR. The OVF flag must be cleared to 0 in the interrupt handling routine.

**Table 11.1 WDT Interrupt Source**

Name	Interrupt Source	Interrupt Flag	DMAC Activation
WOVI	TCNT overflow	OVF	Impossible

## 11.5 Usage Notes

### 11.5.1 Notes on Register Access

The watchdog timer's TCNT, TCSR, and RSTCSR registers differ from other registers in being more difficult to write to. The procedures for writing to and reading these registers are given below.

#### (1) Writing to TCNT, TCSR, and RSTCSR

TCNT and TCSR must be written to by a word transfer instruction. They cannot be written to by a byte transfer instruction.

For writing, TCNT and TCSR are assigned to the same address. Accordingly, perform data transfer as shown in figure 11.4. The transfer instruction writes the lower byte data to TCNT or TCSR.

To write to RSTCSR, execute a word transfer instruction for address H'FFA6. A byte transfer instruction cannot be used to write to RSTCSR.

The method of writing 0 to the WOVF bit in RSTCSR differs from that of writing to the RSTE bit in RSTCSR. Perform data transfer as shown in figure 11.4.

At data transfer, the transfer instruction clears the WOVF bit to 0, but has no effect on the RSTE bit. To write to the RSTE bit, perform data transfer as shown in figure 11.4. In this case, the transfer instruction writes the value in bit 6 of the lower byte to the RSTE bit, but has no effect on the WOVF bit.

**Figure 11.4 Writing to TCNT, TCSR, and RSTCSR**

## (2) Reading from TCNT, TCSR, and RSTCSR

These registers can be read from in the same way as other registers. For reading, TCSR is assigned to address H'FFA4, TCNT to address H'FFA5, and RSTCSR to address H'FFA7.

### 11.5.2 Conflict between Timer Counter (TCNT) Write and Increment

If a TCNT clock pulse is generated during the T2 state of a TCNT write cycle, the write takes priority and the timer counter is not incremented. Figure 11.5 shows this operation.

**Figure 11.5 Conflict between TCNT Write and Increment**

### 11.5.3 Changing Values of Bits CKS2 to CKS0

If bits CKS2 to CKS0 in TCSR are written to while the WDT is operating, errors could occur in the incrementation. The watchdog timer must be stopped (by clearing the TME bit to 0) before the values of bits CKS2 to CKS0 are changed.

### 11.5.4 Switching between Watchdog Timer Mode and Interval Timer Mode

If the timer mode is switched from watchdog timer mode to interval timer mode while the WDT is operating, errors could occur in the incrementation. The watchdog timer must be stopped (by clearing the TME bit to 0) before switching the timer mode.

### **11.5.5 Transition to Watchdog Timer Mode or Software Standby Mode**

When the WDT operates in watchdog timer mode, a transition to software standby mode is not made even when the SLEEP instruction is executed when the SSBY bit in SBYCR is set to 1. Instead, a transition to sleep mode is made.

To transit to software standby mode, the SLEEP instruction must be executed after halting the WDT (clearing the TME bit to 0).

When the WDT operates in interval timer mode, a transition to software standby mode is made through execution of the SLEEP instruction when the SSBY bit in SBYCR is set to 1.

## Section 12 Serial Communication Interface (SCI)

This LSI has two independent serial communication interface (SCI) channels. The SCI can handle both asynchronous and clocked synchronous serial communication. Asynchronous serial data communication can be carried out with standard asynchronous communication chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communication Interface Adapter (ACIA). A function is also provided for serial communication between processors (multiprocessor communication function). The SCI also supports the smart card (IC card) interface conforming to ISO/IEC 7816-3 (Identification Card) as an extended asynchronous communication mode. Figure 12.1 shows a block diagram of the SCI.

### 12.1 Features

- Choice of asynchronous or clocked synchronous serial communication mode
- Full-duplex communication capability

The transmitter and receiver are mutually independent, enabling transmission and reception to be executed simultaneously. Double-buffering is used in both the transmitter and the receiver, enabling continuous transmission and continuous reception of serial data.

- On-chip baud rate generator allows any bit rate to be selected

The external clock can be selected as a transfer clock source (except for the smart card interface).

- Choice of LSB-first or MSB-first transfer (except in the case of asynchronous mode 7-bit data)
- Four interrupt sources

The interrupt sources are transmit-end, transmit-data-empty, receive-data-full, and receive error. The transmit-data-empty and receive-data-full interrupt sources can activate the DMAC.

- Module stop mode can be set

#### Asynchronous Mode:

- Data length: 7 or 8 bits
- Stop bit length: 1 or 2 bits
- Parity: Even, odd, or none
- Receive error detection: Parity, overrun, and framing errors
- Break detection: Break can be detected by reading the RxD pin level directly in case of a framing error

**Clocked Synchronous Mode:**

- Data length: 8 bits
- Receive error detection: Overrun errors

**Smart Card Interface:**

- An error signal can be automatically transmitted on detection of a parity error during reception
- Data can be automatically re-transmitted on receiving an error signal during transmission
- Both direct convention and inverse convention are supported

**Figure 12.1 Block Diagram of SCI**

## 12.2 Input/Output Pins

Table 12.1 lists the pin configuration of the SCI.

**Table 12.1 Pin Configuration**

Channel	Pin Name*	I/O	Function
3	SCK3	I/O	Channel 3 clock input/output
	RxD3	Input	Channel 3 receive data input
	TxD3	Output	Channel 3 transmit data output
4	SCK4	I/O	Channel 4 clock input/output
	RxD4	Input	Channel 4 receive data input
	TxD4	Output	Channel 4 transmit data output

Note: \* Pin names SCK, RxD, and TxD are used in the text for all channels, omitting the channel designation.

## 12.3 Register Descriptions

The SCI has the following registers. Some bits in the serial mode register (SMR), serial status register (SSR), and serial control register (SCR) have different functions in different modes: Normal serial communication interface mode and smart card interface mode. The bits, therefore, are described separately for each mode in the corresponding register sections.

Channel 3:

- Receive shift register\_3 (RSR\_3)
- Transmit shift register\_3 (TSR\_3)
- Receive data register\_3 (RDR\_3)
- Transmit data register\_3 (TDR\_3)
- Serial mode register\_3 (SMR\_3)
- Serial control register\_3 (SCR\_3)
- Serial status register\_3 (SSR\_3)
- Smart card mode register\_3 (SCMR\_3)
- Bit rate register\_3 (BRR\_3)

Channel 4:

- Receive shift register\_4 (RSR\_4)
- Transmit shift register\_4 (TSR\_4)
- Receive data register\_4 (RDR\_4)
- Transmit data register\_4 (TDR\_4)
- Serial mode register\_4 (SMR\_4)
- Serial control register\_4 (SCR\_4)
- Serial status register\_4 (SSR\_4)
- Smart card mode register\_4 (SCMR\_4)
- Bit rate register\_4 (BRR\_4)

### 12.3.1 Receive Shift Register (RSR)

RSR is a shift register which is used to receive serial data input from the RxD pin and converts it into parallel data. When one frame of data has been received, it is transferred to RDR automatically. RSR cannot be directly accessed by the CPU.

### 12.3.2 Receive Data Register (RDR)

RDR is an 8-bit register that stores receive data. When the SCI has received one frame of serial data, it transfers the received serial data from RSR to RDR where it is stored. This allows RSR to receive the next data. Since RSR and RDR function as a double buffer in this way, continuous receive operations can be performed. After confirming that the RDRF bit in SSR is set to 1, read RDR only once. RDR cannot be written to by the CPU.

Bit	7	6	5	4	3	2	1	0
Bit Name								
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

### 12.3.3 Transmit Data Register (TDR)

TDR is an 8-bit register that stores transmit data. When the SCI detects that TSR is empty, it transfers the transmit data written in TDR to TSR and starts transmission. The double-buffered structures of TDR and TSR enables continuous serial transmission. If the next transmit data has already been written to TDR when one frame of data is transmitted, the SCI transfers the written data to TSR to continue transmission. Although TDR can be read from or written to by the CPU at all times, to achieve reliable serial transmission, write transmit data to TDR for only once after confirming that the TDRE bit in SSR is set to 1.

Bit	7	6	5	4	3	2	1	0
Bit Name								
Initial Value	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

### 12.3.4 Transmit Shift Register (TSR)

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI first automatically transfers transmit data from TDR to TSR, then sends the data to the TxD pin. TSR cannot be directly accessed by the CPU.

### 12.3.5 Serial Mode Register (SMR)

SMR is used to set the SCI's serial transfer format and select the baud rate generator clock source. Some bits in SMR have different functions in normal mode and smart card interface mode.

- When SMIF in SCMR = 0

Bit	7	6	5	4	3	2	1	0
Bit Name	C/ $\bar{A}$	CHR	PE	O/ $\bar{E}$	STOP	MP	CKS1	CKS0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

- When SMIF in SCMR = 1

Bit	7	6	5	4	3	2	1	0
Bit Name	GM	BLK	PE	O/ $\bar{E}$	BCP1	BCP0	CKS1	CKS0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

#### Bit Functions in Normal Serial Communication Interface Mode (When SMIF in SCMR = 0):

Bit	Bit Name	Initial Value	R/W	Description
7	C/ $\bar{A}$	0	R/W	Communication Mode 0: Asynchronous mode 1: Clocked synchronous mode
6	CHR	0	R/W	Character Length (valid only in asynchronous mode) 0: Selects 8 bits as the data length. 1: Selects 7 bits as the data length. LSB-first is fixed and the MSB (bit 7) in TDR is not transmitted in transmission. In clocked synchronous mode, a fixed data length of 8 bits is used.

Bit	Bit Name	Initial Value	R/W	Description
5	PE	0	R/W	<p>Parity Enable (valid only in asynchronous mode)</p> <p>When this bit is set to 1, the parity bit is added to transmit data before transmission, and the parity bit is checked in reception. For a multiprocessor format, parity bit addition and checking are not performed regardless of the PE bit setting.</p>
4	O/ $\bar{E}$	0	R/W	<p>Parity Mode (valid only when the PE bit is 1 in asynchronous mode)</p> <p>0: Selects even parity. 1: Selects odd parity.</p>
3	STOP	0	R/W	<p>Stop Bit Length (valid only in asynchronous mode)</p> <p>Selects the stop bit length in transmission.</p> <p>0: 1 stop bit 1: 2 stop bits</p> <p>In reception, only the first stop bit is checked. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.</p>
2	MP	0	R/W	<p>Multiprocessor Mode (valid only in asynchronous mode)</p> <p>When this bit is set to 1, the multiprocessor function is enabled. The PE bit and O/<math>\bar{E}</math> bit settings are invalid in multiprocessor mode.</p>
1	CKS1	0	R/W	Clock Select 1, 0
0	CKS0	0	R/W	<p>These bits select the clock source for the baud rate generator.</p> <p>00: P<math>\phi</math> clock (n = 0) 01: P<math>\phi</math>/4 clock (n = 1) 10: P<math>\phi</math>/16 clock (n = 2) 11: P<math>\phi</math>/64 clock (n = 3)</p> <p>For the relation between the settings of these bits and the baud rate, see section 12.3.9, Bit Rate Register (BRR). n is the decimal display of the value of n in BRR (see section 12.3.9, Bit Rate Register (BRR)).</p>

**Bit Functions in Smart Card Interface Mode (When SMIF in SCMR = 1):**

Bit	Bit Name	Initial Value	R/W	Description
7	GM	0	R/W	GSM Mode  Setting this bit to 1 allows GSM mode operation. In GSM mode, the TEND set timing is put forward to 11.0 etu from the start and the clock output control function is appended. For details, see sections 12.7.6, Data Transmission (Except in Block Transfer Mode) and 12.7.8, Clock Output Control.
6	BLK	0	R/W	Setting this bit to 1 allows block transfer mode operation. For details, see section 12.7.3, Block Transfer Mode.
5	PE	0	R/W	Parity Enable (valid only in asynchronous mode)  When this bit is set to 1, the parity bit is added to transmit data before transmission, and the parity bit is checked in reception. Set this bit to 1 in smart card interface mode.
4	O $\bar{E}$	0	R/W	Parity Mode (valid only when the PE bit is 1 in asynchronous mode)  0: Selects even parity 1: Selects odd parity  For details on the usage of this bit in smart card interface mode, see section 12.7.2, Data Format (Except in Block Transfer Mode).
3	BCP1	0	R/W	Basic Clock Pulse 1,0
2	BCP0	0	R/W	These bits select the number of basic clock cycles in a 1-bit data transfer time in smart card interface mode.  00: 32 clock cycles (S = 32) 01: 64 clock cycles (S = 64) 10: 372 clock cycles (S = 372) 11: 256 clock cycles (S = 256)  For details, see section 12.7.4, Receive Data Sampling Timing and Reception Margin. S is described in section 12.3.9, Bit Rate Register (BRR).

Bit	Bit Name	Initial Value	R/W	Description
1	CKS1	0	R/W	Clock Select 1,0
0	CKS0	0	R/W	These bits select the clock source for the baud rate generator. 00: P $\phi$ clock (n = 0) 01: P $\phi$ /4 clock (n = 1) 10: P $\phi$ /16 clock (n = 2) 11: P $\phi$ /64 clock (n = 3) For the relation between the settings of these bits and the baud rate, see section 12.3.9, Bit Rate Register (BRR). n is the decimal display of the value of n in BRR (see section 12.3.9, Bit Rate Register (BRR)).

Note: etu (Elementary Time Unit): 1-bit transfer time

### 12.3.6 Serial Control Register (SCR)

SCR is a register that enables/disables the following SCI transfer operations and interrupt requests, and selects the transfer clock source. For details on interrupt requests, see section 12.8, Interrupt Sources. Some bits in SCR have different functions in normal mode and smart card interface mode.

- When SMIF in SCMR = 0

Bit	7	6	5	4	3	2	1	0
Bit Name	TIE	RIE	TE	RE	MPIE	TEIE	CKE1	CKE0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

- When SMIF in SCMR = 1

Bit	7	6	5	4	3	2	1	0
Bit Name	TIE	RIE	TE	RE	MPIE	TEIE	CKE1	CKE0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

**Bit Functions in Normal Serial Communication Interface Mode (When SMIF in SCMR = 0):**

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	0	R/W	<p>Transmit Interrupt Enable</p> <p>When this bit is set to 1, a TXI interrupt request is enabled.</p> <p>A TXI interrupt request can be cancelled by reading 1 from the TDRE flag and then clearing the flag to 0, or by clearing the TIE bit to 0.</p>
6	RIE	0	R/W	<p>Receive Interrupt Enable</p> <p>When this bit is set to 1, RXI and ERI interrupt requests are enabled.</p> <p>RXI and ERI interrupt requests can be cancelled by reading 1 from the RDRF, FER, PER, or ORER flag and then clearing the flag to 0, or by clearing the RIE bit to 0.</p>
5	TE	0	R/W	<p>Transmit Enable</p> <p>When this bit is set to 1, transmission is enabled. Under this condition, serial transmission is started by writing transmit data to TDR, and clearing the TDRE flag in SSR to 0. Note that SMR should be set prior to setting the TE bit to 1 in order to designate the transmission format.</p> <p>If transmission is halted by clearing this bit to 0, the TDRE flag in SSR is fixed 1.</p>
4	RE	0	R/W	<p>Receive Enable</p> <p>When this bit is set to 1, reception is enabled. Under this condition, serial reception is started by detecting the start bit in asynchronous mode or the synchronous clock input in clocked synchronous mode. Note that SMR should be set prior to setting the RE bit to 1 in order to designate the reception format.</p> <p>Even if reception is halted by clearing this bit to 0, the RDRF, FER, PER, and ORER flags are not affected and the previous value is retained.</p>

Bit	Bit Name	Initial Value	R/W	Description
3	MPIE	0	R/W	<p>Multiprocessor Interrupt Enable (valid only when the MP bit in SMR is 1 in asynchronous mode)</p> <p>When this bit is set to 1, receive data in which the multiprocessor bit is 0 is skipped, and setting of the RDRF, FER, and ORER status flags in SSR is disabled. On receiving data in which the multiprocessor bit is 1, this bit is automatically cleared and normal reception is resumed. For details, see section 12.5, Multiprocessor Communication Function.</p> <p>When receive data including MPB = 0 in SSR is being received, transfer of the received data from RSR to RDR, detection of reception errors, and the settings of RDRF, FER, and ORER flags in SSR are not performed. When receive data including MPB = 1 is received, the MPB bit in SSR is set to 1, the MPIE bit is automatically cleared to 0, and RXI and ERI interrupt requests (in the case where the TIE and RIE bits in SCR are set to 1) and setting of the FER and ORER flags are enabled.</p>
2	TEIE	0	R/W	<p>Transmit End Interrupt Enable</p> <p>When this bit is set to 1, a TEI interrupt request is enabled. A TEI interrupt request can be cancelled by reading 1 from the TDRE flag and then clearing the flag to 0 in order to clear the TEND flag to 0, or by clearing the TEIE bit to 0.</p>
1	CKE1	0	R/W	Clock Enable 1, 0
0	CKE0	0	R/W	<p>These bits select the clock source and SCK pin function.</p> <ul style="list-style-type: none"> <li>• Asynchronous mode</li> </ul> <p>00: On-chip baud rate generator (SCK pin functions as I/O port.)</p> <p>01: On-chip baud rate generator (Outputs a clock with the same frequency as the bit rate from the SCK pin.)</p> <p>1X: External clock (Inputs a clock with a frequency 16 times the bit rate from the SCK pin.)</p> <ul style="list-style-type: none"> <li>• Clocked synchronous mode</li> </ul> <p>0X: Internal clock (SCK pin functions as clock output.)</p> <p>1X: External clock (SCK pin functions as clock input.)</p>

Note: X: Don't care

### 12.3.7 Serial Status Register (SSR)

SSR is a register containing status flags of the SCI and multiprocessor bits for transfer. TDRE, RDRF, ORER, PER, and FER can only be cleared. Some bits in SSR have different functions in normal mode and smart card interface mode.

- When SMIF in SCMR = 0

Bit	7	6	5	4	3	2	1	0
Bit Name	TDRE	RDRF	ORER	FER	PER	TEND	MPB	MPBT
Initial Value	1	0	0	0	0	1	0	0
R/W	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R	R	R/W

Note: \* Only 0 can be written, to clear the flag.

- When SMIF in SCMR = 1

Bit	7	6	5	4	3	2	1	0
Bit Name	TDRE	RDRF	ORER	ERS	PER	TEND	MPB	MPBT
Initial Value	1	0	0	0	0	1	0	0
R/W	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R	R	R/W

Note: \* Only 0 can be written, to clear the flag.

**Bit Functions in Normal Serial Communication Interface Mode (When SMIF in SCMR = 0):**

Bit	Bit Name	Initial Value	R/W	Description
7	TDRE	1	R/(W)*	<p>Transmit Data Register Empty</p> <p>Indicates whether TDR contains transmit data.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>• When the TE bit in SCR is 0</li> <li>• When data is transferred from TDR to TSR</li> </ul> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• When 0 is written to TDRE after reading TDRE = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> <li>• When a TXI interrupt request is issued allowing DMAC to write data to TDR</li> </ul>
6	RDRF	0	R/(W)*	<p>Receive Data Register Full</p> <p>Indicates whether receive data is stored in RDR.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• When serial reception ends normally and receive data is transferred from RSR to RDR</li> </ul> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• When 0 is written to RDRF after reading RDRF = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> <li>• When an RXI interrupt request is issued allowing DMAC to read data from RDR</li> </ul> <p>The RDRF flag is not affected and retains its previous value when the RE bit in SCR is cleared to 0.</p> <p>Note that when the next serial reception is completed while the RDRF flag is being set to 1, an overrun error occurs and the received data is lost.</p>

Bit	Bit Name	Initial Value	R/W	Description
5	ORER	0	R/(W)*	<p>Overrun Error</p> <p>Indicates that an overrun error has occurred during reception and the reception ends abnormally.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>When the next serial reception is completed while RDRF = 1</li> </ul> <p>In RDR, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, subsequent serial reception cannot be performed. Note that, in clocked synchronous mode, serial transmission also cannot continue.</p> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>When 0 is written to ORER after reading ORER = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> </ul> <p>Even when the RE bit in SCR is cleared, the ORER flag is not affected and retains its previous value.</p>

### 12.3.8 Smart Card Mode Register (SCMR)

SCMR selects smart card interface mode and its format.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	—	—	SDIR	SINV	—	SMIF
Initial Value	1	1	1	1	0	0	1	0
R/W	R	R	R	R	R/W	R/W	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	All 1	R	Reserved These are read-only bits and cannot be modified.
3	SDIR	0	R/W	Smart Card Data Transfer Direction Selects the serial/parallel conversion format. 0: Transfer with LSB-first 1: Transfer with MSB-first This bit is valid only when the 8-bit data format is used for transmission/reception; when the 7-bit data format is used, data is always transmitted/received with LSB-first.
2	SINV	0	R/W	Smart Card Data Invert Inverts the transmit/receive data logic level. This bit does not affect the logic level of the parity bit. To invert the parity bit, invert the O/ $\bar{E}$ bit in SMR. 0: TDR contents are transmitted as they are. Receive data is stored as it is in RDR. 1: TDR contents are inverted before being transmitted. Receive data is stored in inverted form in RDR.
1	—	1	R	Reserved This is a read-only bit and cannot be modified.
0	SMIF	0	R/W	Smart Card Interface Mode Select When this bit is set to 1, smart card interface mode is selected. 0: Normal asynchronous or clocked synchronous mode 1: Smart card interface mode

### 12.3.9 Bit Rate Register (BRR)

BRR is an 8-bit register that adjusts the bit rate. As the SCI performs baud rate generator control independently for each channel, different bit rates can be set for each channel. Table 12.2 shows the relationships between the N setting in BRR and bit rate B for normal asynchronous mode and clocked synchronous mode, and smart card interface mode. The initial value of BRR is H'FF, and it can be read from or written to by the CPU at all times.

**Table 12.2 Relationships between N Setting in BRR and Bit Rate B**

Mode	Bit Rate	Error
Asynchronous mode	$N = \frac{P\phi \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	$\text{Error (\%)} = \left\{ \frac{P\phi \times 10^6}{B \times 64 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
Clocked synchronous mode	$N = \frac{P\phi \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	
Smart card interface mode	$N = \frac{P\phi \times 10^6}{S \times 2^{2n+1} \times B} - 1$	$\text{Error (\%)} = \left\{ \frac{P\phi \times 10^6}{B \times S \times 2^{2n+1} \times (N+1)} - 1 \right\} \times 100$

[Legend]

B: Bit rate (bit/s)

N: BRR setting for baud rate generator ( $0 \leq N \leq 255$ )

$P\phi$ : Operating frequency (MHz)

n and S: Determined by the SMR settings shown in the following table.

SMR Setting			SMR Setting		
CKS1	CKS0	n	BCP1	BCP0	S
0	0	0	0	0	32
0	1	1	0	1	64
1	0	2	1	0	372
1	1	3	1	1	256

Table 12.3 shows sample N settings in BRR in normal asynchronous mode. Table 12.4 shows the maximum bit rate settable for each operating frequency. Tables 12.6 and 12.8 show sample N settings in BRR in clocked synchronous mode and smart card interface mode, respectively. In smart card interface mode, the number of basic clock cycles S in a 1-bit data transfer time can be selected. For details, see section 12.7.4, Receive Data Sampling Timing and Reception Margin. Tables 12.5 and 12.7 show the maximum bit rates with external clock input.

## 12.4 Operation in Asynchronous Mode

Figure 12.2 shows the general format for asynchronous serial communication. One frame consists of a start bit (low level), followed by transmit/receive data, a parity bit, and finally stop bits (high level). In asynchronous serial communication, the communication line is usually held in the mark state (high level). The SCI monitors the communication line, and when it goes to the space state (low level), recognizes a start bit and starts serial communication. Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communication. Both the transmitter and the receiver also have a double-buffered structure, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

**Figure 12.2 Data Format in Asynchronous Communication  
(Example with 8-Bit Data, Parity, Two Stop Bits)**

### 12.4.1 Data Transfer Format

Table 12.10 shows the data transfer formats that can be used in asynchronous mode. Any of 12 transfer formats can be selected according to the SMR setting. For details on the multiprocessor bit, see section 12.5, Multiprocessor Communication Function.

**Table 12.10 Serial Transfer Formats (Asynchronous Mode)**

SMR Settings				Serial Transmit/Receive Format and Frame Length													
CHR	PE	MP	STOP	1	2	3	4	5	6	7	8	9	10	11	12		
0	0	0	0	S	8-bit data								STOP				
0	0	0	1	S	8-bit data								STOP	STOP			
0	1	0	0	S	8-bit data								P	STOP			
0	1	0	1	S	8-bit data								P	STOP	STOP		
1	0	0	0	S	7-bit data							STOP					
1	0	0	1	S	7-bit data							STOP	STOP				
1	1	0	0	S	7-bit data							P	STOP				
1	1	0	1	S	7-bit data							P	STOP	STOP			
0	—	1	0	S	8-bit data								MPB	STOP			
0	—	1	1	S	8-bit data								MPB	STOP	STOP		
1	—	1	0	S	7-bit data							MPB	STOP				
1	—	1	1	S	7-bit data							MPB	STOP	STOP			

[Legend]

S: Start bit

STOP: Stop bit

P: Parity bit

MPB: Multiprocessor bit

### 12.4.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a basic clock with a frequency of 16 times the bit rate. In reception, the SCI samples the falling edge of the start bit using the basic clock, and performs internal synchronization. Since receive data is sampled at the rising edge of the 8th pulse of the basic clock, data is latched at the middle of each bit, as shown in figure 12.3. Thus the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100 \quad [\%] \quad \cdots \text{Formula (1)}$$

M: Reception margin

N: Ratio of bit rate to clock ( $N = 16$ )

D: Duty cycle of clock ( $D = 0.5$  to  $1.0$ )

L: Frame length ( $L = 9$  to  $12$ )

F: Absolute value of clock frequency deviation

Assuming values of  $F = 0$  and  $D = 0.5$  in formula (1), the reception margin is determined by the formula below.

$$M = \left( 0.5 - \frac{1}{2 \times 16} \right) \times 100 \quad [\%] = 46.875\%$$

However, this is only the computed value, and a margin of 20% to 30% should be allowed in system design.

**Figure 12.3 Receive Data Sampling Timing in Asynchronous Mode**

### 12.4.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCK pin can be selected as the SCI's transfer clock, according to the setting of the  $C/\bar{A}$  bit in SMR and the CKE1 and CKE0 bits in SCR. When an external clock is input to the SCK pin, the clock frequency should be 16 times the bit rate used.

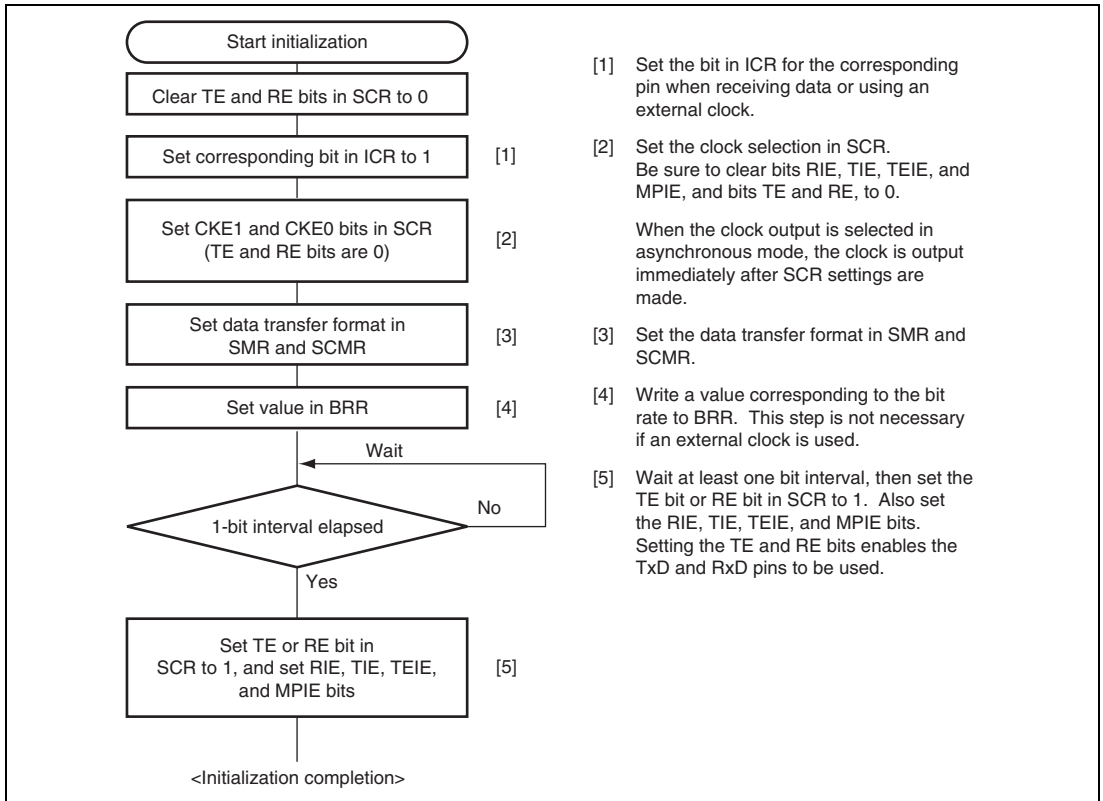

When the SCI is operated on an internal clock, the clock can be output from the SCK pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is such that the rising edge of the clock is in the middle of the transmit data, as shown in figure 12.4.

**Figure 12.4 Phase Relation between Output Clock and Transmit Data  
(Asynchronous Mode)**

### 12.4.4 SCI Initialization (Asynchronous Mode)

Before transmitting and receiving data, first clear the TE and RE bits in SCR to 0, then initialize the SCI as described in a sample flowchart in figure 12.5. When the operating mode, transfer format, etc., is changed, the TE and RE bits must be cleared to 0 before making the change. When the TE bit is cleared to 0, the TDRE flag is set to 1. Note that clearing the RE bit to 0 does not initialize the RDRF, PER, FER, and ORER flags, or RDR. When the external clock is used in asynchronous mode, the clock must be supplied even during initialization.

**Figure 12.5 Sample SCI Initialization Flowchart**

### 12.4.5 Serial Data Transmission (Asynchronous Mode)

Figure 12.6 shows an example of the operation for transmission in asynchronous mode. In transmission, the SCI operates as described below.

1. The SCI monitors the TDRE flag in SSR, and if it is cleared to 0, recognizes that data has been written to TDR, and transfers the data from TDR to TSR.
2. After transferring data from TDR to TSR, the SCI sets the TDRE flag to 1 and starts transmission. If the TIE bit in SCR is set to 1 at this time, a TXI interrupt request is generated. Because the TXI interrupt processing routine writes the next transmit data to TDR before transmission of the current transmit data has finished, continuous transmission can be enabled.
3. Data is sent from the TxD pin in the following order: start bit, transmit data, parity bit or multiprocessor bit (may be omitted depending on the format), and stop bit.
4. The SCI checks the TDRE flag at the timing for sending the stop bit.
5. If the TDRE flag is 0, the next transmit data is transferred from TDR to TSR, the stop bit is sent, and then serial transmission of the next frame is started.
6. If the TDRE flag is 1, the TEND flag in SSR is set to 1, the stop bit is sent, and then the mark state is entered in which 1 is output. If the TEIE bit in SCR is set to 1 at this time, a TEI interrupt request is generated.

Figure 12.7 shows a sample flowchart for transmission in asynchronous mode.

**Figure 12.6 Example of Operation for Transmission in Asynchronous Mode  
(Example with 8-Bit Data, Parity, One Stop Bit)**

**Figure 12.7 Sample Serial Transmission Flowchart**

### 12.4.6 Serial Data Reception (Asynchronous Mode)

Figure 12.8 shows an example of the operation for reception in asynchronous mode. In serial reception, the SCI operates as described below.

1. The SCI monitors the communication line, and if a start bit is detected, performs internal synchronization, stores receive data in RSR, and checks the parity bit and stop bit.
2. If an overrun error (when reception of the next data is completed while the RDRF flag in SSR is still set to 1) occurs, the ORER bit in SSR is set to 1. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR. The RDRF flag remains to be set to 1.
3. If a parity error is detected, the PER bit in SSR is set to 1 and receive data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated.
4. If a framing error (when the stop bit is 0) is detected, the FER bit in SSR is set to 1 and receive data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated.
5. If reception finishes successfully, the RDRF bit in SSR is set to 1, and receive data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an RXI interrupt request is generated. Because the RXI interrupt processing routine reads the receive data transferred to RDR before reception of the next receive data has finished, continuous reception can be enabled.

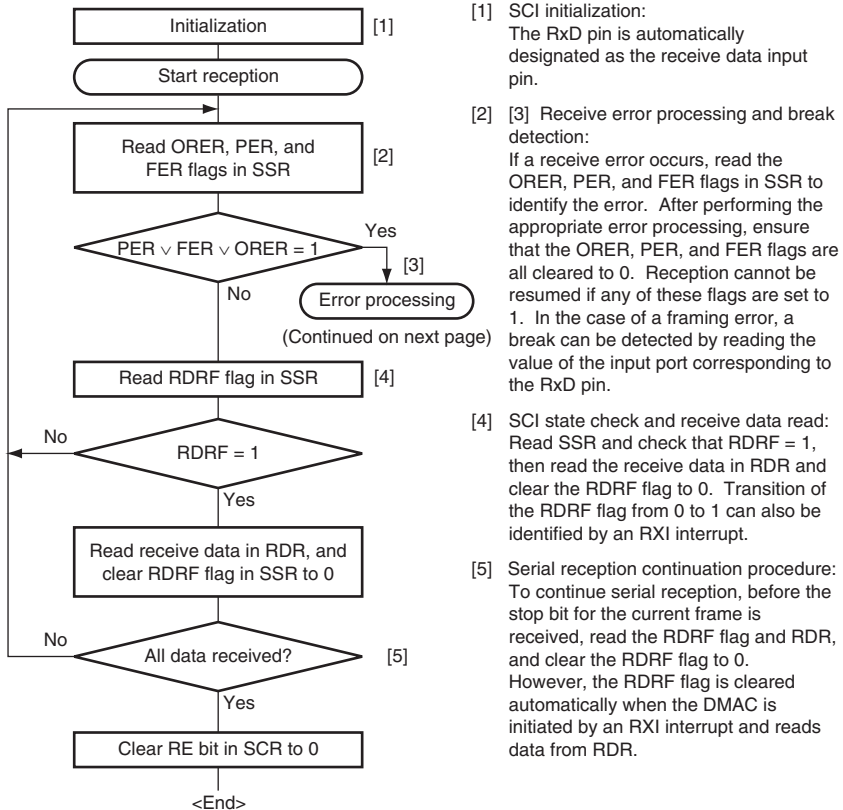

**Figure 12.8 Example of SCI Operation for Reception  
(Example with 8-Bit Data, Parity, One Stop Bit)**

Table 12.11 shows the states of the SSR status flags and receive data handling when a receive error is detected. If a receive error is detected, the RDRF flag retains its state before receiving data. Reception cannot be resumed while a receive error flag is set to 1. Accordingly, clear the ORER, FER, PER, and RDRF bits to 0 before resuming reception. Figure 12.9 shows a sample flowchart for serial data reception.

**Table 12.11 SSR Status Flags and Receive Data Handling**

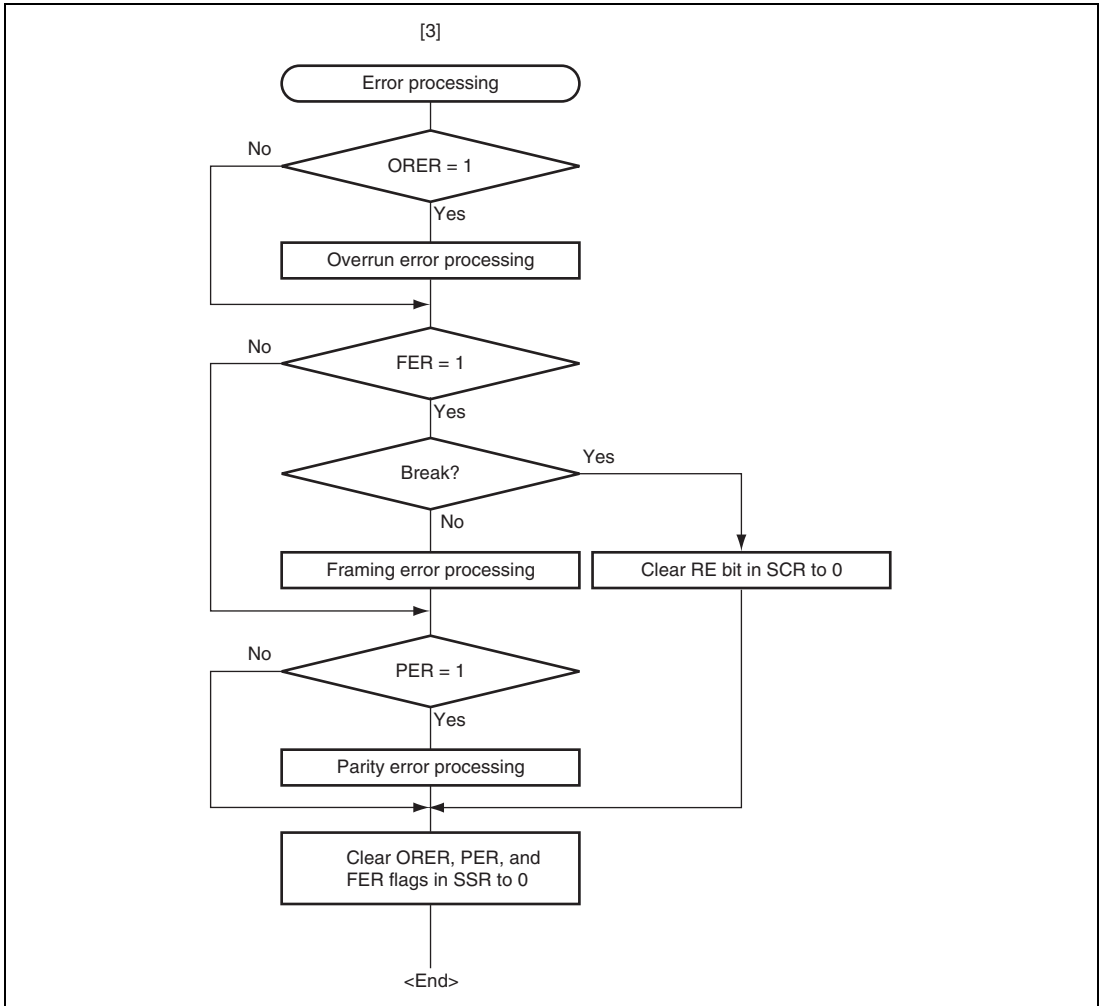

SSR Status Flag				Receive Data	Receive Error Type
RDRF*	ORER	FER	PER		
1	1	0	0	Lost	Overrun error
0	0	1	0	Transferred to RDR	Framing error
0	0	0	1	Transferred to RDR	Parity error
1	1	1	0	Lost	Overrun error + framing error
1	1	0	1	Lost	Overrun error + parity error
0	0	1	1	Transferred to RDR	Framing error + parity error
1	1	1	1	Lost	Overrun error + framing error + parity error

Note: \* The RDRF flag retains the state it had before data reception.

- [1] SCI initialization:  
The RxD pin is automatically designated as the receive data input pin.
- [2] [3] Receive error processing and break detection:  
If a receive error occurs, read the ORER, PER, and FER flags in SSR to identify the error. After performing the appropriate error processing, ensure that the ORER, PER, and FER flags are all cleared to 0. Reception cannot be resumed if any of these flags are set to 1. In the case of a framing error, a break can be detected by reading the value of the input port corresponding to the RxD pin.
- [4] SCI state check and receive data read:  
Read SSR and check that  $RDRF = 1$ , then read the receive data in RDR and clear the RDRF flag to 0. Transition of the RDRF flag from 0 to 1 can also be identified by an RXI interrupt.
- [5] Serial reception continuation procedure:  
To continue serial reception, before the stop bit for the current frame is received, read the RDRF flag and RDR, and clear the RDRF flag to 0. However, the RDRF flag is cleared automatically when the DMAC is initiated by an RXI interrupt and reads data from RDR.

**Figure 12.9 Sample Serial Reception Flowchart (1)**

**Figure 12.9 Sample Serial Reception Flowchart (2)**

## 12.5 Multiprocessor Communication Function

Use of the multiprocessor communication function enables data transfer to be performed among a number of processors sharing communication lines by means of asynchronous serial communication using the multiprocessor format, in which a multiprocessor bit is added to the transfer data. When multiprocessor communication is carried out, each receiving station is addressed by a unique ID code. The serial communication cycle consists of two component cycles: an ID transmission cycle which specifies the receiving station, and a data transmission cycle for the specified receiving station. The multiprocessor bit is used to differentiate between the ID transmission cycle and the data transmission cycle. If the multiprocessor bit is 1, the cycle is an ID transmission cycle, and if the multiprocessor bit is 0, the cycle is a data transmission cycle. Figure 12.10 shows an example of inter-processor communication using the multiprocessor format. The transmitting station first sends data which includes the ID code of the receiving station and a multiprocessor bit set to 1. It then transmits data added with the multiprocessor bit cleared to 0. The receiving station skips data until data with the multiprocessor bit set to 1 is sent. When data with the multiprocessor bit set to 1 is received, the receiving station compares that data with its own ID. The station whose ID matches then receives the data sent next. Stations whose ID does not match continue to skip data until data with the multiprocessor bit set to 1 is again received.

The SCI uses the MPIE bit in SCR to implement this function. When the MPIE bit is set to 1, transfer of receive data from RSR to RDR, error flag detection, and setting the SSR status flags, RDRF, FER, and ORER in SSR to 1 are prohibited until data with the multiprocessor bit set to 1 is received. On reception of a receive character with the multiprocessor bit set to 1, the MPBR bit in SSR is set to 1 and the MPIE bit is automatically cleared, thus normal reception is resumed. If the RIE bit in SCR is set to 1 at this time, an RXI interrupt is generated.

When the multiprocessor format is selected, the parity bit setting is invalid. All other bit settings are the same as those in normal asynchronous mode. The clock used for multiprocessor communication is the same as that in normal asynchronous mode.

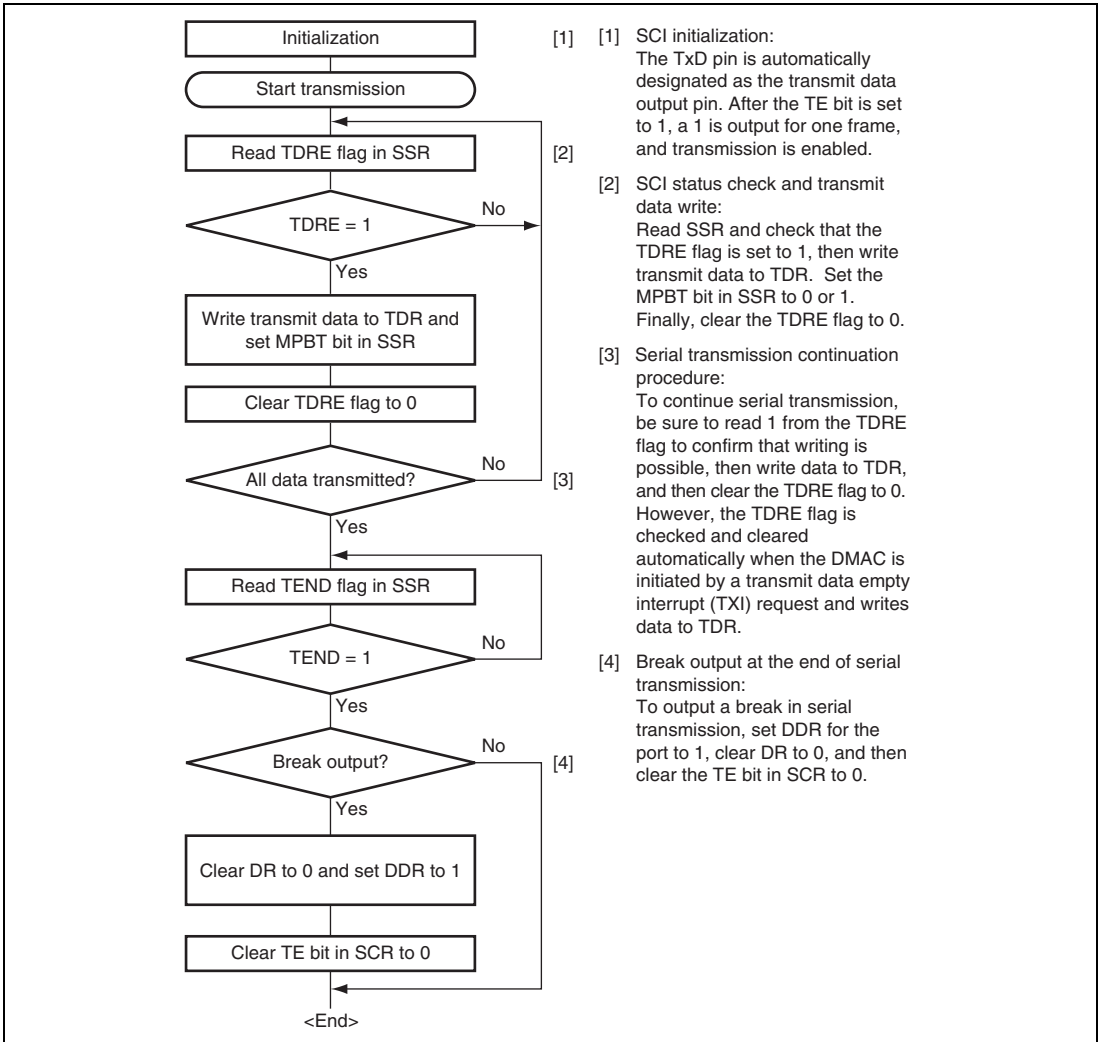

**Figure 12.10 Example of Communication Using Multiprocessor Format  
(Transmission of Data H'AA to Receiving Station A)**

### 12.5.1 Multiprocessor Serial Data Transmission

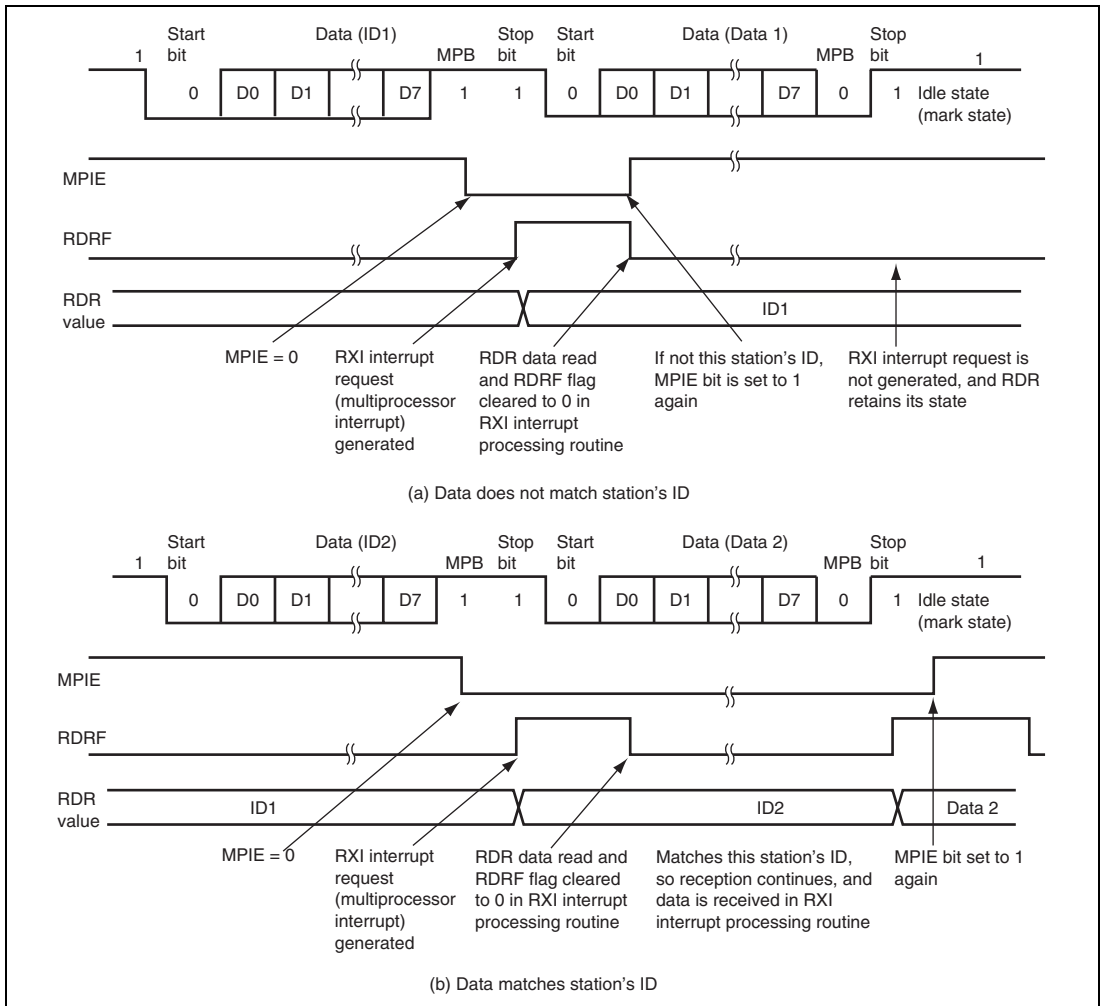

Figure 12.11 shows a sample flowchart for multiprocessor serial data transmission. For an ID transmission cycle, set the MPBT bit in SSR to 1 before transmission. For a data transmission cycle, clear the MPBT bit in SSR to 0 before transmission. All other SCI operations are the same as those in asynchronous mode.

**Figure 12.11 Sample Multiprocessor Serial Transmission Flowchart**

## 12.5.2 Multiprocessor Serial Data Reception

Figure 12.13 shows a sample flowchart for multiprocessor serial data reception. If the MPIE bit in SCR is set to 1, data is skipped until data with a 1 multiprocessor bit is sent. On receiving data with a 1 multiprocessor bit, the receive data is transferred to RDR. An RXI interrupt request is generated at this time. All other SCI operations are the same as in asynchronous mode. Figure 12.12 shows an example of SCI operation for multiprocessor format reception.

**Figure 12.12 Example of SCI Operation for Reception  
(Example with 8-Bit Data, Multiprocessor Bit, One Stop Bit)**

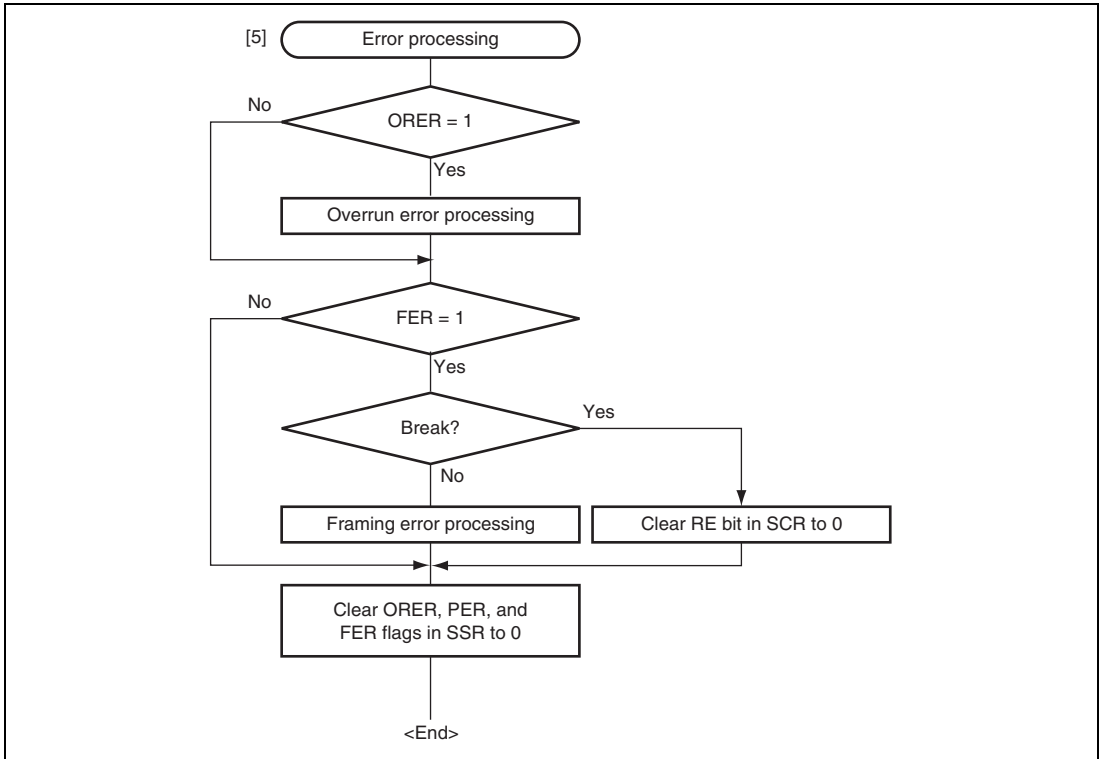

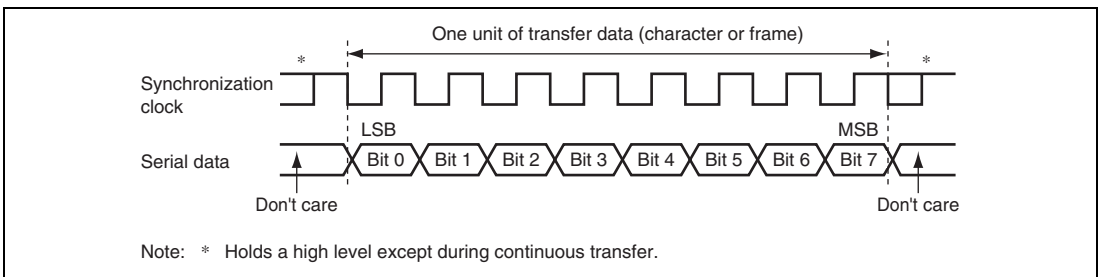

Figure 12.13 Sample Multiprocessor Serial Reception Flowchart (1)

**Figure 12.13 Sample Multiprocessor Serial Reception Flowchart (2)**

## 12.6 Operation in Clocked Synchronous Mode

Figure 12.14 shows the general format for clocked synchronous communication. In clocked synchronous mode, data is transmitted or received in synchronization with clock pulses. One character in transfer data consists of 8-bit data. In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the MSB output state. In clocked synchronous mode, no parity bit or multiprocessor bit is added. Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communication by use of a common clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

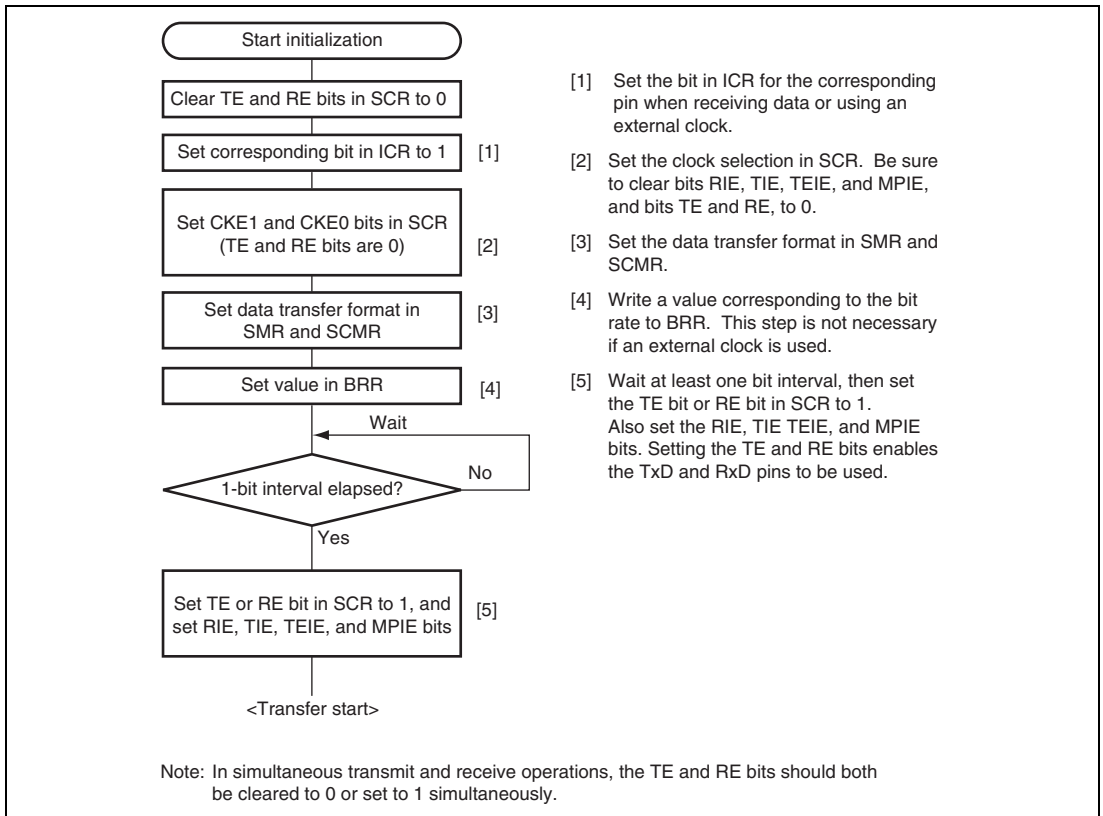

**Figure 12.14 Data Format in Clocked Synchronous Communication (LSB-First)**

### 12.6.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCK pin can be selected, according to the setting of the CKE1 and CKE0 bits in SCR. When the SCI is operated on an internal clock, the synchronization clock is output from the SCK pin. Eight synchronization clock pulses are output in the transfer of one character, and when no transfer is performed the clock is fixed high. Note that in the case of reception only, the synchronization clock is output until an overrun error occurs or until the RE bit is cleared to 0.

## 12.6.2 SCI Initialization (Clocked Synchronous Mode)

Before transmitting and receiving data, first clear the TE and RE bits in SCR to 0, then initialize the SCI as described in a sample flowchart in figure 12.15. When the operating mode, transfer format, etc., is changed, the TE and RE bits must be cleared to 0 before making the change. When the TE bit is cleared to 0, the TDRE flag is set to 1. However, clearing the RE bit to 0 does not initialize the RDRF, PER, FER, and ORER flags, or RDR.

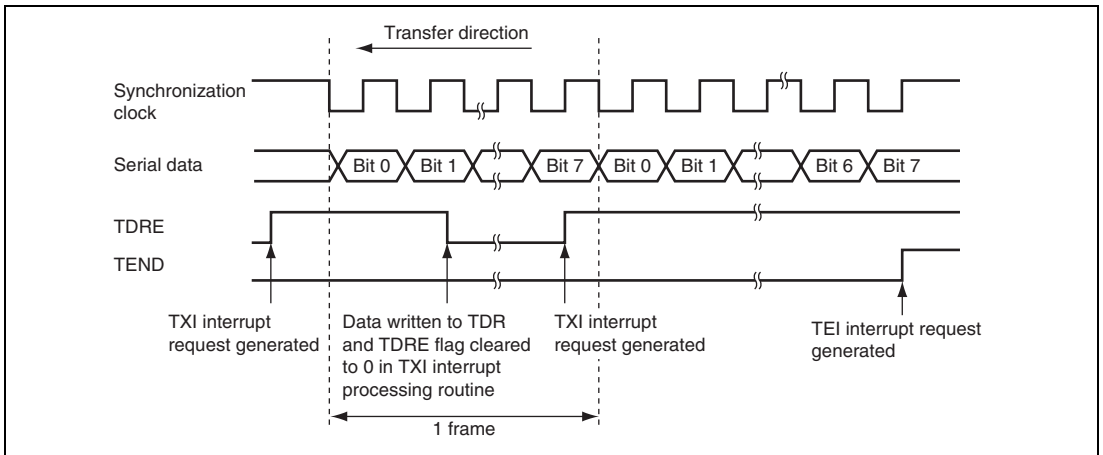

**Figure 12.15 Sample SCI Initialization Flowchart**

### 12.6.3 Serial Data Transmission (Clocked Synchronous Mode)

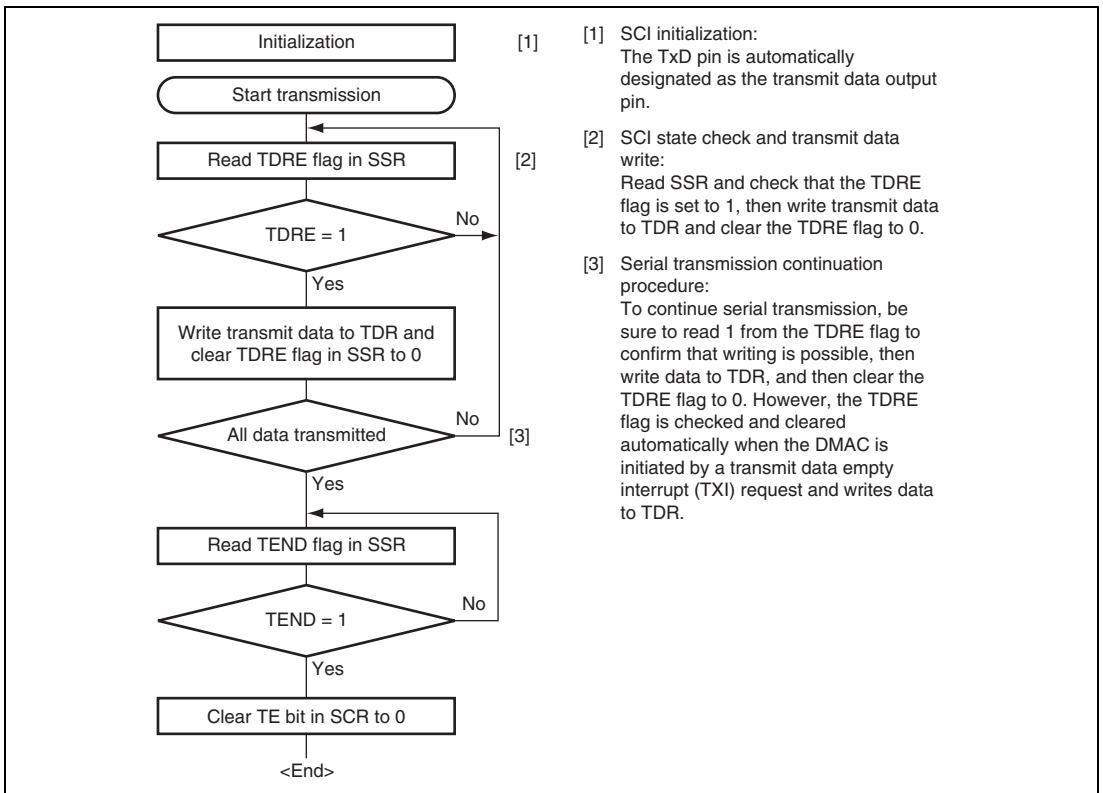

Figure 12.16 shows an example of the operation for transmission in clocked synchronous mode. In transmission, the SCI operates as described below.

1. The SCI monitors the TDRE flag in SSR, and if it is 0, recognizes that data has been written to TDR, and transfers the data from TDR to TSR.
2. After transferring data from TDR to TSR, the SCI sets the TDRE flag to 1 and starts transmission. If the TIE bit in SCR is set to 1 at this time, a TXI interrupt request is generated. Because the TXI interrupt processing routine writes the next transmit data to TDR before transmission of the current transmit data has finished, continuous transmission can be enabled.
3. 8-bit data is sent from the TxD pin synchronized with the output clock when clock output mode has been specified and synchronized with the input clock when use of an external clock has been specified.
4. The SCI checks the TDRE flag at the timing for sending the last bit.
5. If the TDRE flag is cleared to 0, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame is started.
6. If the TDRE flag is set to 1, the TEND flag in SSR is set to 1, and the TxD pin retains the output state of the last bit. If the TEIE bit in SCR is set to 1 at this time, a TEI interrupt request is generated. The SCK pin is fixed high.

Figure 12.17 shows a sample flowchart for serial data transmission. Even if the TDRE flag is cleared to 0, transmission will not start while a receive error flag (ORER, FER, or PER) is set to 1. Make sure to clear the receive error flags to 0 before starting transmission. Note that clearing the RE bit to 0 does not clear the receive error flags.

**Figure 12.16 Example of Operation for Transmission in Clocked Synchronous Mode**

**Figure 12.17 Sample Serial Transmission Flowchart**

### 12.6.4 Serial Data Reception (Clocked Synchronous Mode)

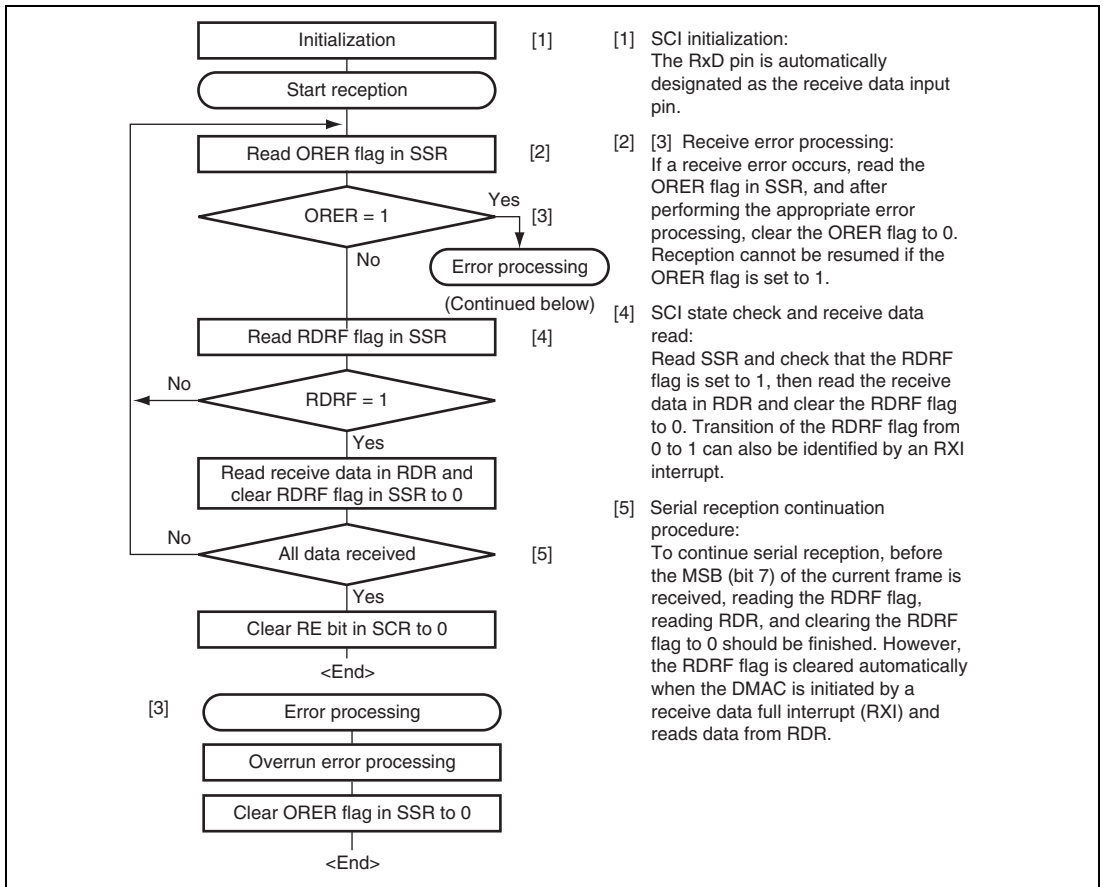

Figure 12.18 shows an example of SCI operation for reception in clocked synchronous mode. In serial reception, the SCI operates as described below.

1. The SCI performs internal initialization in synchronization with a synchronization clock input or output, starts receiving data, and stores the receive data in RSR.
2. If an overrun error (when reception of the next data is completed while the RDRF flag in SSR is still set to 1) occurs, the ORER bit in SSR is set to 1. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR. The RDRF flag remains to be set to 1.
3. If reception finishes successfully, the RDRF bit in SSR is set to 1, and receive data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an RXI interrupt request is generated. Because the RXI interrupt processing routine reads the receive data transferred to RDR before reception of the next receive data has finished, continuous reception can be enabled.

**Figure 12.18 Example of Operation for Reception in Clocked Synchronous Mode**

Transfer cannot be resumed while a receive error flag is set to 1. Accordingly, clear the ORER, FER, PER, and RDRF bits to 0 before resuming reception. Figure 12.19 shows a sample flowchart for serial data reception.

**Figure 12.19 Sample Serial Reception Flowchart**

### 12.6.5 Simultaneous Serial Data Transmission and Reception (Clocked Synchronous Mode)

Figure 12.20 shows a sample flowchart for simultaneous serial transmit and receive operations. After initializing the SCI, the following procedure should be used for simultaneous serial data transmit and receive operations. To switch from transmit mode to simultaneous transmit and receive mode, after checking that the SCI has finished transmission and the TDRE and TEND flags are set to 1, clear the TE bit to 0. Then simultaneously set both the TE and RE bits to 1 with a single instruction. To switch from receive mode to simultaneous transmit and receive mode, after checking that the SCI has finished reception, clear the RE bit to 0. Then after checking that the RDRF bit and receive error flags (ORER, FER, and PER) are cleared to 0, simultaneously set both the TE and RE bits to 1 with a single instruction.

Note: When switching from transmit or receive operation to simultaneous transmit and receive operations, first clear the TE bit and RE bit to 0, then set both these bits to 1 simultaneously.

- [1] SCI initialization:  
The TxD pin is designated as the transmit data output pin, and the RxD pin is designated as the receive data input pin, enabling simultaneous transmit and receive operations.
- [2] SCI state check and transmit data write:  
Read SSR and check that the TDRE flag is set to 1, then write transmit data to TDR and clear the TDRE flag to 0. Transition of the TDRE flag from 0 to 1 can also be identified by a TXI interrupt.
- [3] Receive error processing:  
If a receive error occurs, read the ORER flag in SSR, and after performing the appropriate error processing, clear the ORER flag to 0. Reception cannot be resumed if the ORER flag is set to 1.
- [4] SCI state check and receive data read:  
Read SSR and check that the RDRF flag is set to 1, then read the receive data in RDR and clear the RDRF flag to 0. Transition of the RDRF flag from 0 to 1 can also be identified by an RXI interrupt.
- [5] Serial transmission/reception continuation procedure:  
To continue serial transmission/reception, before the MSB (bit 7) of the current frame is received, finish reading the RDRF flag, reading RDR, and clearing the RDRF flag to 0. Also, before the MSB (bit 7) of the current frame is transmitted, read 1 from the TDRE flag to confirm that writing is possible. Then write data to TDR and clear the TDRE flag to 0. However, the TDRE flag is checked and cleared automatically when the DMAC is initiated by a transmit data empty interrupt (TXI) request and writes data to TDR. Similarly, the RDRF flag is cleared automatically when the DMAC is initiated by a receive data full interrupt (RXI) and reads data from RDR.

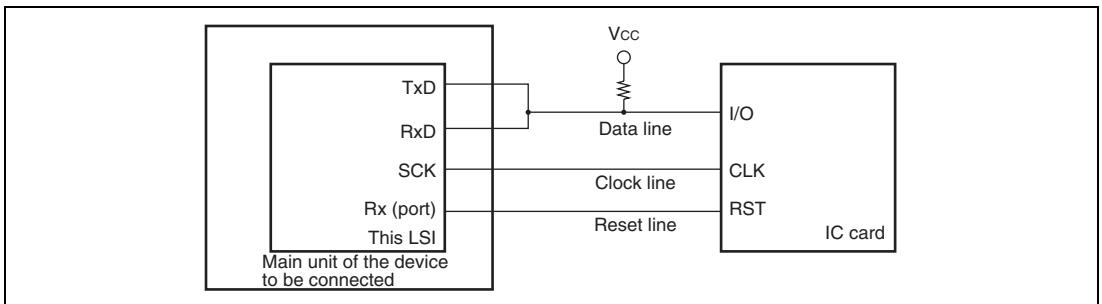

**Figure 12.20 Sample Flowchart of Simultaneous Serial Transmission and Reception**

## 12.7 Operation in Smart Card Interface Mode

The SCI supports the IC card (smart card) interface, conforming to ISO/IEC 7816-3 (Identification Card) standard, as an extended serial communication interface function. Smart card interface mode can be selected using the appropriate register.

### 12.7.1 Sample Connection

Figure 12.21 shows a sample connection between the smart card and this LSI. As in the figure, since this LSI communicates with the IC card using a single transmission line, interconnect the TxD and RxD pins and pull up the data transmission line to  $V_{cc}$  using a resistor. Setting the RE and TE bits to 1 with the IC card not connected enables closed transmission/reception allowing self diagnosis. To supply the IC card with the clock pulses generated by the SCI, input the SCK pin output to the CLK pin of the IC card. A reset signal can be supplied via the output port of this LSI.

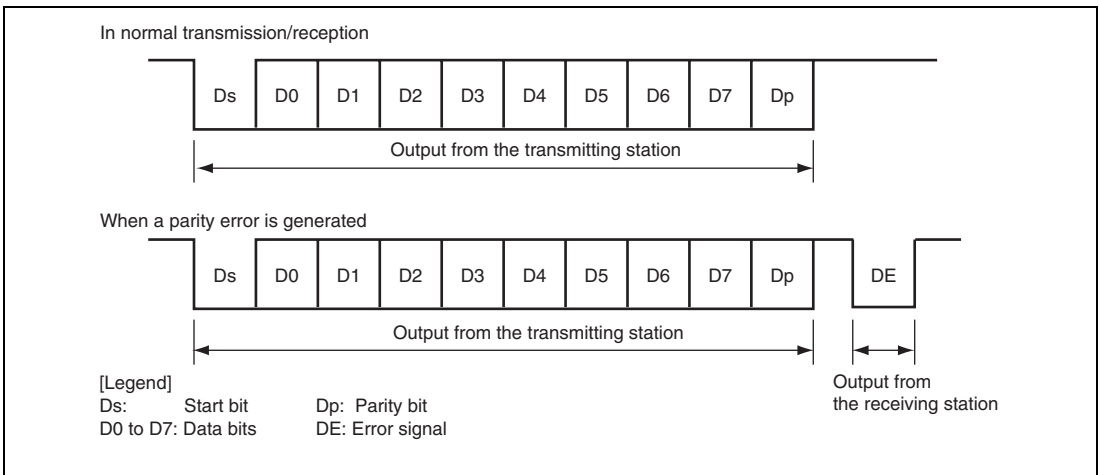

**Figure 12.21 Pin Connection for Smart Card Interface**

### 12.7.2 Data Format (Except in Block Transfer Mode)

Figure 12.22 shows the data transfer formats in smart card interface mode.

- One frame contains 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etu (elementary time unit: time required for transferring one bit) is secured as a guard time after the end of the parity bit before the start of the next frame.
- If a parity error is detected during reception, a low error signal is output for 1 etu after 10.5 etu has passed from the start bit.
- If an error signal is sampled during transmission, the same data is automatically re-transmitted after at least 2 etu.

**Figure 12.22 Data Formats in Normal Smart Card Interface Mode**

For communication with the IC cards of the direct convention and inverse convention types, follow the procedure below.

**Figure 12.23 Direct Convention ( $SDIR = SINV = O/\bar{E} = 0$ )**

For the direct convention type, logic levels 1 and 0 correspond to states Z and A, respectively, and data is transferred with LSB-first as the start character, as shown in figure 12.23. Therefore, data in the start character in the figure is H'3B. When using the direct convention type, write 0 to both the SDIR and SINV bits in SCMR. Write 0 to the  $O\bar{E}$  bit in SMR in order to use even parity, which is prescribed by the smart card standard.

**Figure 12.24 Inverse Convention (SDIR = SINV =  $O\bar{E}$  = 1)**

For the inverse convention type, logic levels 1 and 0 correspond to states A and Z, respectively and data is transferred with MSB-first as the start character, as shown in figure 12.24. Therefore, data in the start character in the figure is H'3F. When using the inverse convention type, write 1 to both the SDIR and SINV bits in SCMR. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to state Z. Since the SNIV bit of this LSI only inverts data bits D7 to D0, write 1 to the  $O\bar{E}$  bit in SMR to invert the parity bit in both transmission and reception.

### 12.7.3 Block Transfer Mode

Block transfer mode is different from normal smart card interface mode in the following respects.

- Even if a parity error is detected during reception, no error signal is output. Since the PER bit in SSR is set by error detection, clear the PER bit before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is secured as a guard time after the end of the parity bit before the start of the next frame.
- Since the same data is not re-transmitted during transmission, the TEND flag is set 11.5 etu after transmission start.
- Although the ERS flag in block transfer mode displays the error signal status as in normal smart card interface mode, the flag is always read as 0 because no error signal is transferred.

### 12.7.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode. In this mode, the SCI can operate on a basic clock with a frequency of 32, 64, 372, or 256 times the bit rate according to the BCP1 and BCP0 bit settings (the frequency is always 16 times the bit rate in normal asynchronous mode). At reception, the falling edge of the start bit is sampled using the basic clock in order to perform internal synchronization. Receive data is sampled on the 16th, 32nd, 186th and 128th rising edges of the basic clock so that it can be latched at the middle of each bit as shown in figure 12.25. The reception margin here is determined by the following formula.

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\%$$

M: Reception margin (%)

N: Ratio of bit rate to clock (N = 32, 64, 372, 256)

D: Duty cycle of clock (D = 0 to 1.0)

L: Frame length (L = 10)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the above formula, the reception margin is determined by the formula below.

$$M = \left( 0.5 - \frac{1}{2 \times 372} \right) \times 100\% = 49.866\%$$

**Figure 12.25 Receive Data Sampling Timing in Smart Card Interface Mode  
(When Clock Frequency is 372 Times the Bit Rate)**

### 12.7.5 Initialization

Before transmitting and receiving data, initialize the SCI using the following procedure. Initialization is also necessary before switching from transmission to reception and vice versa.

1. Clear the TE and RE bits in SCR to 0.
2. Set the ICR bit of the corresponding pin to 1.
3. Clear the error flags ERS, PER, and ORER in SSR to 0.
4. Set the GM, BLK,  $O/\bar{E}$ , BCP1, BCP0, CKS1, and CKS0 bits in SMR appropriately. Also set the PE bit to 1.
5. Set the SMIF, SDIR, and SINV bits in SCMR appropriately. When the DDR corresponding to the TxD pin is cleared to 0, the TxD and RxD pins are changed from port pins to SCI pins, placing the pins into high impedance state.
6. Set the value corresponding to the bit rate in BRR.
7. Set the CKE1 and CKE0 bits in SCR appropriately. Clear the TIE, RIE, TE, RE, MPIE, and TEIE bits to 0 simultaneously.

When the CKE0 bit is set to 1, the SCK pin is allowed to output clock pulses.

8. Set the TIE, RIE, TE, and RE bits in SCR appropriately after waiting for at least a 1-bit interval. Setting the TE and RE bits to 1 simultaneously is prohibited except for self diagnosis.

To switch from reception to transmission, first verify that reception has completed, then initialize the SCI. At the end of initialization, RE and TE should be set to 0 and 1, respectively. Reception completion can be verified by reading the RDRF, PER, or ORER flag. To switch from transmission to reception, first verify that transmission has completed, then initialize the SCI. At the end of initialization, TE and RE should be set to 0 and 1, respectively. Transmission completion can be verified by reading the TEND flag.

### 12.7.6 Data Transmission (Except in Block Transfer Mode)

Data transmission in smart card interface mode (except in block transfer mode) is different from that in normal serial communication interface mode in that an error signal is sampled and data can be re-transmitted. Figure 12.26 shows the data re-transfer operation during transmission.

1. If an error signal from the receiving end is sampled after one frame of data has been transmitted, the ERS bit in SSR is set to 1. Here, an ERI interrupt request is generated if the RIE bit in SCR is set to 1. Clear the ERS bit to 0 before the next parity bit is sampled.
2. For the frame in which an error signal is received, the TEND bit in SSR is not set to 1. Data is re-transferred from TDR to TSR allowing automatic data retransmission.
3. If no error signal is returned from the receiving end, the ERS bit in SSR is not set to 1.
4. In this case, one frame of data is determined to have been transmitted including re-transfer, and the TEND bit in SSR is set to 1. Here, a TXI interrupt request is generated if the TIE bit in SCR is set to 1. Writing transmit data to TDR starts transmission of the next data.

Figure 12.28 shows a sample flowchart for transmission. All the processing steps are automatically performed using a TXI interrupt request to activate the DMAC. In transmission, the TEND and TDRE flags in SSR are simultaneously set to 1, thus generating a TXI interrupt request if the TIE bit in SCR has been set to 1. This activates the DMAC by a TXI request thus allowing transfer of transmit data if the TXI interrupt request is specified as a source of DMAC activation beforehand. The TDRE and TEND flags are automatically cleared to 0 at data transfer by the DMAC. If an error occurs, the SCI automatically re-transmits the same data. During re-transmission, TEND remains as 0, thus not activating the DMAC. Therefore, the SCI and DMAC automatically transmit the specified number of bytes, including re-transmission in the case of error occurrence. However, the ERS flag is not automatically cleared; the ERS flag must be cleared by previously setting the RIE bit to 1 to enable an ERI interrupt request to be generated at error occurrence.

When transmitting/receiving data using the DMAC, be sure to set and enable the DMAC prior to making SCI settings. For DMAC settings, see section 7, DMA Controller (DMAC).

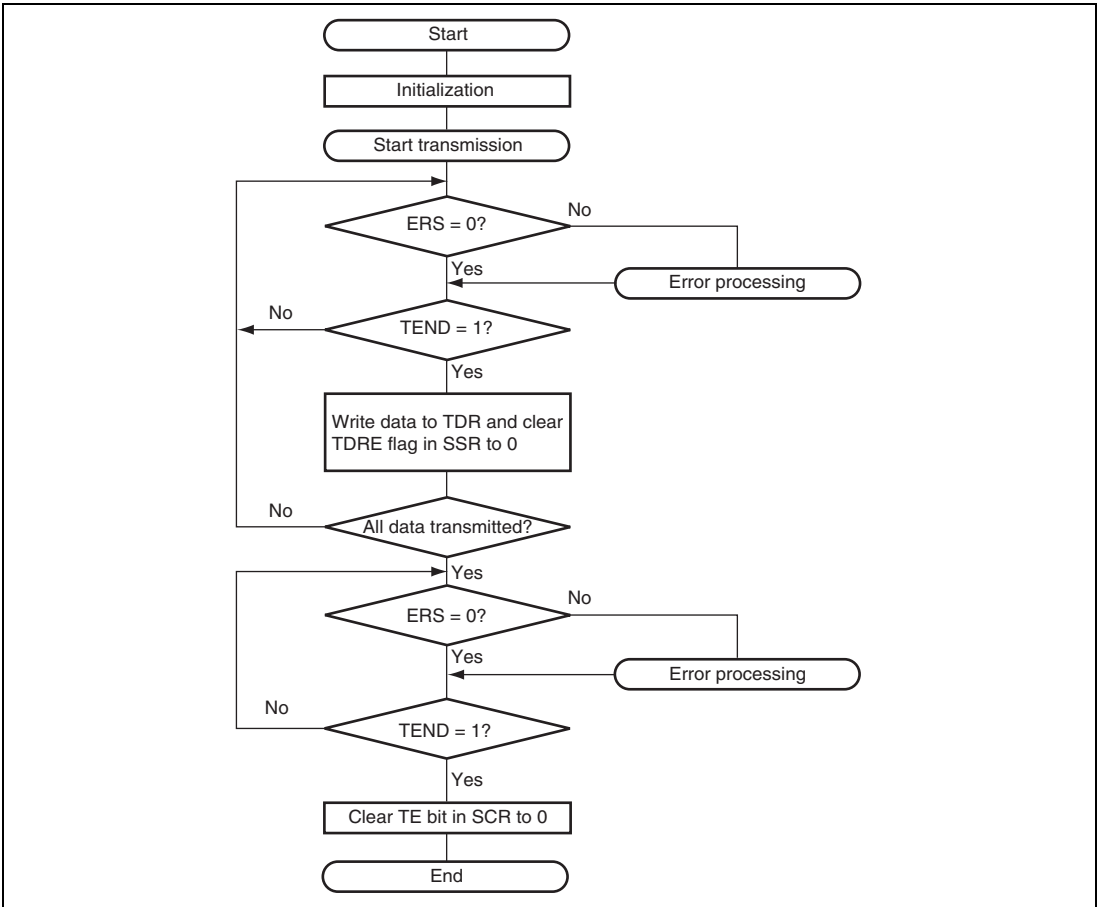

**Figure 12.26 Data Re-Transfer Operation in SCI Transmission Mode**

Note that the TEND flag is set in different timings depending on the GM bit setting in SMR. Figure 12.27 shows the TEND flag set timing.

**Figure 12.27 TEND Flag Set Timing during Transmission**

**Figure 12.28 Sample Transmission Flowchart**

### 12.7.7 Serial Data Reception (Except in Block Transfer Mode)

Data reception in smart card interface mode is similar to that in normal serial communication interface mode. Figure 12.29 shows the data re-transfer operation during reception.

1. If a parity error is detected in receive data, the PER bit in SSR is set to 1. Here, an ERI interrupt request is generated if the RIE bit in SCR is set to 1. Clear the PER bit to 0 before the next parity bit is sampled.
2. For the frame in which a parity error is detected, the RDRF bit in SSR is not set to 1.
3. If no parity error is detected, the PER bit in SSR is not set to 1.
4. In this case, data is determined to have been received successfully, and the RDRF bit in SSR is set to 1. Here, an RXI interrupt request is generated if the RIE bit in SCR is set to 1.

Figure 12.30 shows a sample flowchart for reception. All the processing steps are automatically performed using an RXI interrupt request to activate the DMAC. In reception, setting the RIE bit to 1 allows an RXI interrupt request to be generated when the RDRF flag is set to 1. This activates the DMAC by an RXI request thus allowing transfer of receive data if the RXI interrupt request is specified as a source of DMAC activation beforehand. The RDRF flag is automatically cleared to 0 at data transfer by the DMAC. If an error occurs during reception, i.e., either the ORER or PER flag is set to 1, a transmit/receive error interrupt (ERI) request is generated and the error flag must be cleared. If an error occurs, the DMAC is not activated and receive data is skipped, therefore, the number of bytes of receive data specified in the DMAC is transferred. Even if a parity error occurs and the PER bit is set to 1 in reception, receive data is transferred to RDR, thus allowing the data to be read.

Note: For operations in block transfer mode, see section 12.4, Operation in Asynchronous Mode.

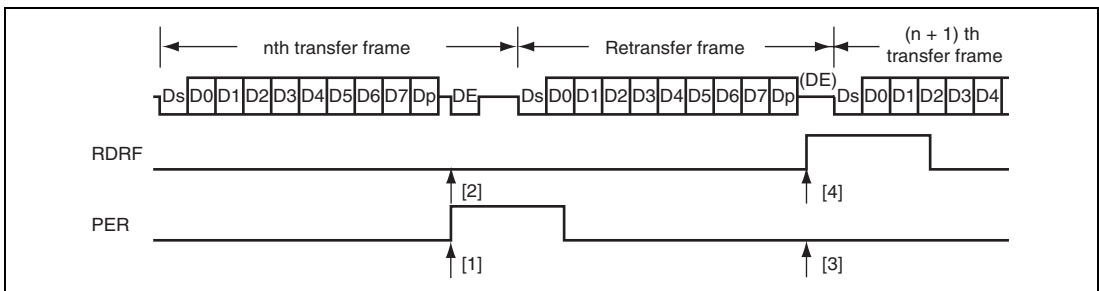

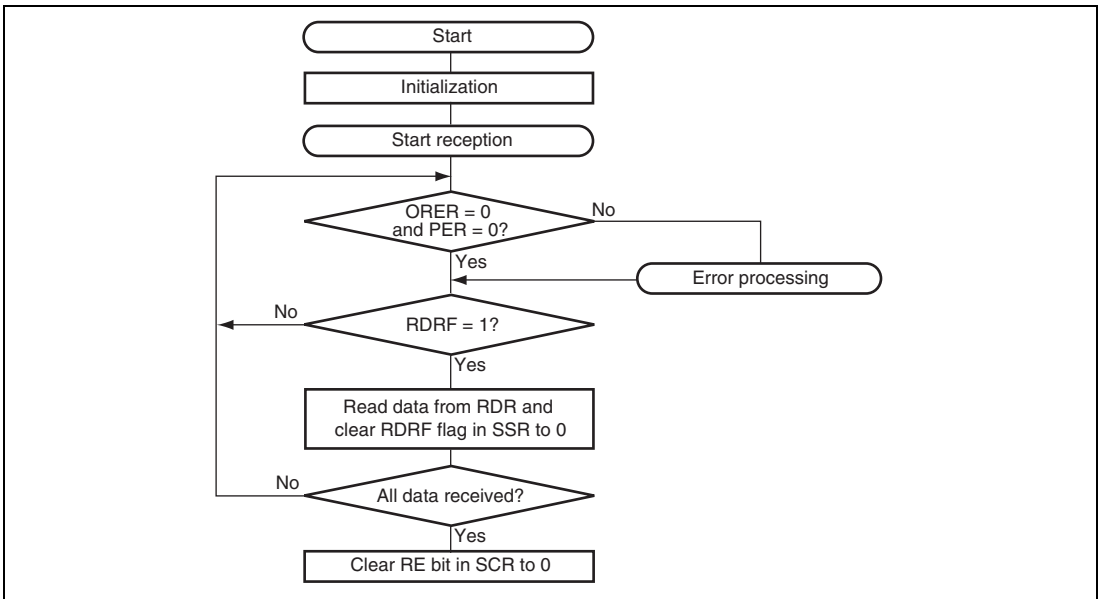

Figure 12.29 Data Re-Transfer Operation in SCI Reception Mode

**Figure 12.30 Sample Reception Flowchart**

### 12.7.8 Clock Output Control

Clock output can be fixed using the CKE1 and CKE0 bits in SCR when the GM bit in SMR is set to 1. Specifically, the minimum width of a clock pulse can be specified.

Figure 12.31 shows an example of clock output fixing timing when the CKE0 bit is controlled with GM = 1 and CKE1 = 0.

**Figure 12.31 Clock Output Fixing Timing**

At power-on and transitions to/from software standby mode, use the following procedure to secure the appropriate clock duty cycle.

- At power-on
 

To secure the appropriate clock duty cycle simultaneously with power-on, use the following procedure.

  1. Initially, port input is enabled in the high-impedance state. To fix the potential level, use a pull-up or pull-down resistor.
  2. Fix the SCK pin to the specified output using the CKE1 bit in SCR.
  3. Set SMR and SCMR to enable smart card interface mode.  
Set the CKE0 bit in SCR to 1 to start clock output.
- At mode switching
  - At transition from smart card interface mode to software standby mode
    1. Set the data register (DR) and data direction register (DDR) corresponding to the SCK pin to the values for the output fixed state in software standby mode.
    2. Write 0 to the TE and RE bits in SCR to stop transmission/reception. Simultaneously, set the CKE1 bit to the value for the output fixed state in software standby mode.
    3. Write 0 to the CKE0 bit in SCR to stop the clock.
    4. Wait for one cycle of the serial clock. In the mean time, the clock output is fixed to the specified level with the duty cycle retained.
    5. Make the transition to software standby mode.
  - At transition from smart card interface mode to software standby mode
    1. Clear software standby mode.
    2. Write 1 to the CKE0 bit in SCR to start clock output. A clock signal with the appropriate duty cycle is then generated.

**Figure 12.32 Clock Stop and Restart Procedure**

## 12.8 Interrupt Sources

### 12.8.1 Interrupts in Normal Serial Communication Interface Mode

Table 12.12 shows the interrupt sources in normal serial communication interface mode. A different interrupt vector is assigned to each interrupt source, and individual interrupt sources can be enabled or disabled using the enable bits in SCR.

When the TDRE flag in SSR is set to 1, a TXI interrupt request is generated. When the TEND flag in SSR is set to 1, a TEI interrupt request is generated. A TXI interrupt request can activate the DMAC to allow data transfer. The TDRE flag is automatically cleared to 0 at data transfer by the DMAC.

When the RDRF flag in SSR is set to 1, an RXI interrupt request is generated. When the ORER, PER, or FER flag in SSR is set to 1, an ERI interrupt request is generated. An RXI interrupt can activate the DMAC to allow data transfer. The RDRF flag is automatically cleared to 0 at data transfer by the DMAC.

A TEI interrupt is requested when the TEND flag is set to 1 while the TEIE bit is set to 1. If a TEI interrupt and a TXI interrupt are requested simultaneously, the TXI interrupt has priority for acceptance. However, note that if the TDRE and TEND flags are cleared to 0 simultaneously by the TXI interrupt processing routine, the SCI cannot branch to the TEI interrupt processing routine later.

**Table 12.12 SCI Interrupt Sources**

Name	Interrupt Source	Interrupt Flag	DMAC Activation	Priority
ERI	Receive error	ORER, FER, or PER	Not possible	High
RXI	Receive data full	RDRF	Possible	▲ ↑
TXI	Transmit data empty	TDRE	Possible	
TEI	Transmit end	TEND	Not possible	Low

## 12.8.2 Interrupts in Smart Card Interface Mode

Table 12.13 shows the interrupt sources in smart card interface mode. A transmit end (TEI) interrupt request cannot be used in this mode.

**Table 12.13 SCI Interrupt Sources**

Name	Interrupt Source	Interrupt Flag	DMAC Activation	Priority
ERI	Receive error or error signal detection	ORER, PER, or ERS	Not possible	High
RXI	Receive data full	RDRF	Possible	↑ Low
TXI	Transmit data empty	TDRE	Possible	

Data transmission/reception using the DMAC is also possible in smart card interface mode, similar to in the normal SCI mode. In transmission, the TEND and TDRE flags in SSR are simultaneously set to 1, thus generating a TXI interrupt. This activates the DMAC by a TXI request thus allowing transfer of transmit data if the TXI request is specified as a source of DMAC activation beforehand. The TDRE and TEND flags are automatically cleared to 0 at data transfer by the DMAC. If an error occurs, the SCI automatically re-transmits the same data. During re-transmission, the TEND flag remains as 0, thus not activating the DMAC. Therefore, the SCI and DMAC automatically transmit the specified number of bytes, including re-transmission in the case of error occurrence. However, the ERS flag in SSR, which is set at error occurrence, is not automatically cleared; the ERS flag must be cleared by previously setting the RIE bit in SCR to 1 to enable an ERI interrupt request to be generated at error occurrence.

When transmitting/receiving data using the DMAC, be sure to set and enable the DMAC prior to making SCI settings. For DMAC settings, see section 7, DMA Controller (DMAC).

In reception, an RXI interrupt request is generated when the RDRF flag in SSR is set to 1. This activates the DMAC by an RXI request thus allowing transfer of receive data if the RXI request is specified as a source of DMAC activation beforehand. The RDRF flag is automatically cleared to 0 at data transfer by the DMAC. If an error occurs, the RDRF flag is not set but the error flag is set. Therefore, the DMAC is not activated and an ERI interrupt request is issued to the CPU instead; the error flag must be cleared.

## 12.9 Usage Notes

### 12.9.1 Module Stop Mode Setting

Operation of the SCI can be disabled or enabled using the module stop control register. The initial setting is for operation of the SCI to be halted. Register access is enabled by clearing module stop mode. For details, refer to section 19, Power-Down Modes.

### 12.9.2 Break Detection and Processing

When framing error detection is performed, a break can be detected by reading the RxD pin value directly. In a break, the input from the RxD pin becomes all 0s, and so the FER flag is set, and the PER flag may also be set. Note that, since the SCI continues the receive operation even after receiving a break, even if the FER flag is cleared to 0, it will be set to 1 again.

### 12.9.3 Mark State and Break Detection

When the TE bit is 0, the TxD pin is used as an I/O port whose direction (input or output) and level are determined by DR and DDR. This can be used to set the TxD pin to mark state (high level) or send a break during serial data transmission. To maintain the communication line in mark state (the state of 1) until TE is set to 1, set both DDR and DR to 1. Since the TE bit is cleared to 0 at this point, the TxD pin becomes an I/O port, and 1 is output from the TxD pin. To send a break during serial transmission, first set DDR to 1 and DR to 0, and then clear the TE bit to 0. When the TE bit is cleared to 0, the transmitter is initialized regardless of the current transmission state, the TxD pin becomes an I/O port, and 0 is output from the TxD pin.

### 12.9.4 Receive Error Flags and Transmit Operations (Clocked Synchronous Mode Only)

Transmission cannot be started when a receive error flag (ORER, FER, or RER) is set to 1, even if the TDRE flag is cleared to 0. Be sure to clear the receive error flags to 0 before starting transmission. Note also that the receive error flags cannot be cleared to 0 even if the RE bit is cleared to 0.

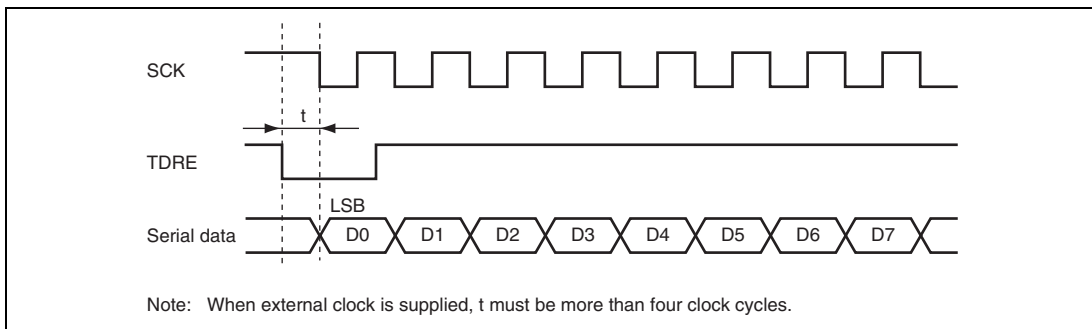

### 12.9.5 Relation between Writing to TDR and TDRE Flag

The TDRE flag in SSR is a status flag which indicates that transmit data has been transferred from TDR to TSR. When the SCI transfers data from TDR to TSR, the TDRE flag is set to 1.

Data can be written to TDR irrespective of the TDRE flag status. However, if new data is written to TDR when the TDRE flag is 0, that is, when the previous data has not been transferred to TSR yet, the previous data in TDR is lost. Be sure to write transmit data to TDR after verifying that the TDRE flag is set to 1.

### 12.9.6 Restrictions on Using DMAC

- When the external clock source is used as a synchronization clock, update TDR by the DMAC and wait for at least five  $P\phi$  clock cycles before allowing the transmit clock to be input. If the transmit clock is input within four clock cycles after TDR modification, the SCI may malfunction (figure 12.33).
- When using the DMAC to read RDR, be sure to set the receive end interrupt (RXI) as the DMAC activation source.

**Figure 12.33 Sample Transmission using DMAC in Clocked Synchronous Mode**

## 12.9.7 SCI Operations during Mode Transitions

### (1) Transmission

Before making the transition to module stop mode or software standby mode, stop the transmit operations ( $TE = TIE = TEIE = 0$ ). TSR, TDR, and SSR are reset. The states of the output pins during module stop mode or software standby mode depend on the port settings, and the pins output a high-level signal after mode cancellation. If the transition is made during data transmission, the data being transmitted will be undefined.

To transmit data in the same transmission mode after mode cancellation, set the TE bit to 1, read SSR, write to TDR, clear TDRE in this order, and then start transmission. To transmit data in a different transmission mode, initialize the SCI first.

Figure 12.34 shows a sample flowchart for mode transition during transmission. Figures 12.35 and 12.36 show the port pin states during mode transition.

### (2) Reception

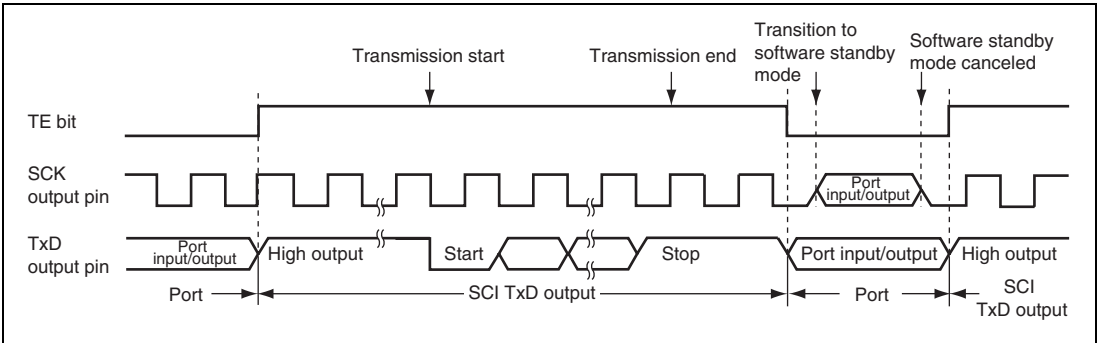

Before making the transition to module stop mode or software standby mode, stop the receive operations ( $RE = 0$ ). RSR, RDR, and SSR are reset. If transition is made during data reception, the data being received will be invalid.

To receive data in the same reception mode after mode cancellation, set the RE bit to 1, and then start reception. To receive data in a different reception mode, initialize the SCI first.

Figure 12.37 shows a sample flowchart for mode transition during reception.

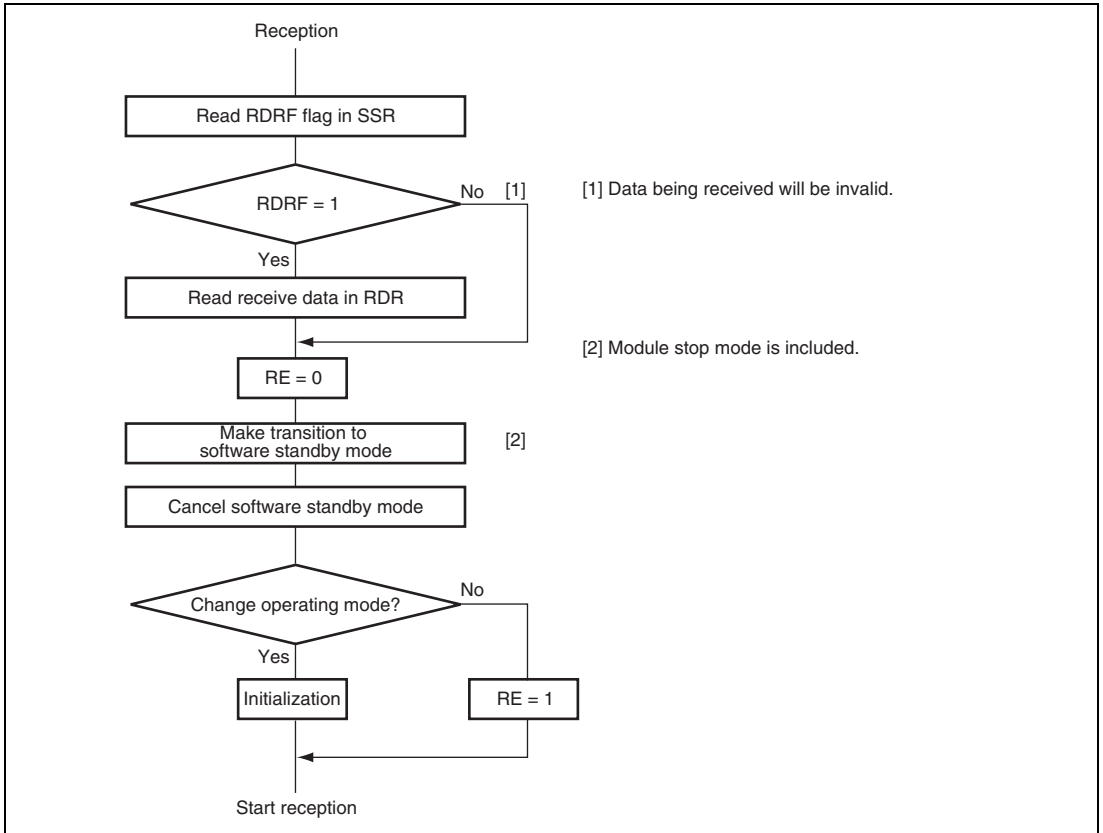

**Figure 12.34 Sample Flowchart for Mode Transition during Transmission**

**Figure 12.35 Port Pin States during Mode Transition (Internal Clock, Asynchronous Transmission)**

**Figure 12.36 Port Pin States during Mode Transition (Internal Clock, Clocked Synchronous Transmission)**

## Section 13 Controller Area Network (RCAN-ET)

### 13.1 Summary

#### 13.1.1 Overview

This document primarily describes the programming interface for the RCAN-ET module. It serves to facilitate the hardware/software interface so that engineers involved in the RCAN-ET implementation can ensure the design is successful.

#### 13.1.2 Scope

The CAN Data Link Controller function is not described in this document. It is the responsibility of the reader to investigate the CAN Specification Document (see references). The interfaces from the CAN Controller are described, in so far as they pertain to the connection with the User Interface.

The programming model is described in some detail. It is not the intention of this document to describe the implementation of the programming interface, but to simply present the interface to the underlying CAN functionality.

The document places no constraints upon the implementation of the RCAN-ET module in terms of process, packaging or power supply criteria. These issues are resolved where appropriate in implementation specifications.

#### 13.1.3 Audience

In particular this document provides the design reference for software authors who are responsible for creating a CAN application using this module.

In the creation of the RCAN-ET user interface LSI engineers must use this document to understand the hardware requirements.

### 13.1.4 References

1. CAN Specification Version 2.0 part A, Robert Bosch GmbH, 1991
2. CAN Specification Version 2.0 part B, Robert Bosch GmbH, 1991
3. Implementation Guide for the CAN Protocol, CAN Specification 2.0 Addendum, CAN In Automation, Erlangen, Germany, 1997
4. Road vehicles - Controller area network (CAN): Part 1: Data link layer and physical signalling (ISO-11898-1, 2003)

### 13.1.5 Features

- Supports CAN specification 2.0B
- Bit timing compliant with ISO-11898-1
- 16 Mailbox version
- 15 programmable Mailboxes for transmit/receive + 1 receive-only mailbox
- Sleep mode for low power consumption and automatic recovery from sleep mode by detecting CAN bus activity
- Programmable receive filter mask (standard and extended identifier) supported by all Mailboxes
- Programmable CAN data rate up to 1MBit/s
- Transmit message queuing with internal priority sorting mechanism against the problem of priority inversion for real-time applications
- Data buffer access without SW handshake requirement in reception
- Flexible micro-controller interface
- Flexible interrupt structure

## 13.2 Architecture

### 13.2.1 Block Diagram

The RCAN-ET device offers a flexible and sophisticated way to organize and control CAN frames, providing the compliance to CAN2.0B Active and ISO-11898-1. The module is formed from 5 different functional entities. These are the Micro Processor Interface (MPI), Mailbox, Mailbox Control and CAN Interface. The figure below shows the block diagram of the RCAN-ET Module. The bus interface timing is designed according to the peripheral bus I/F required for each product.

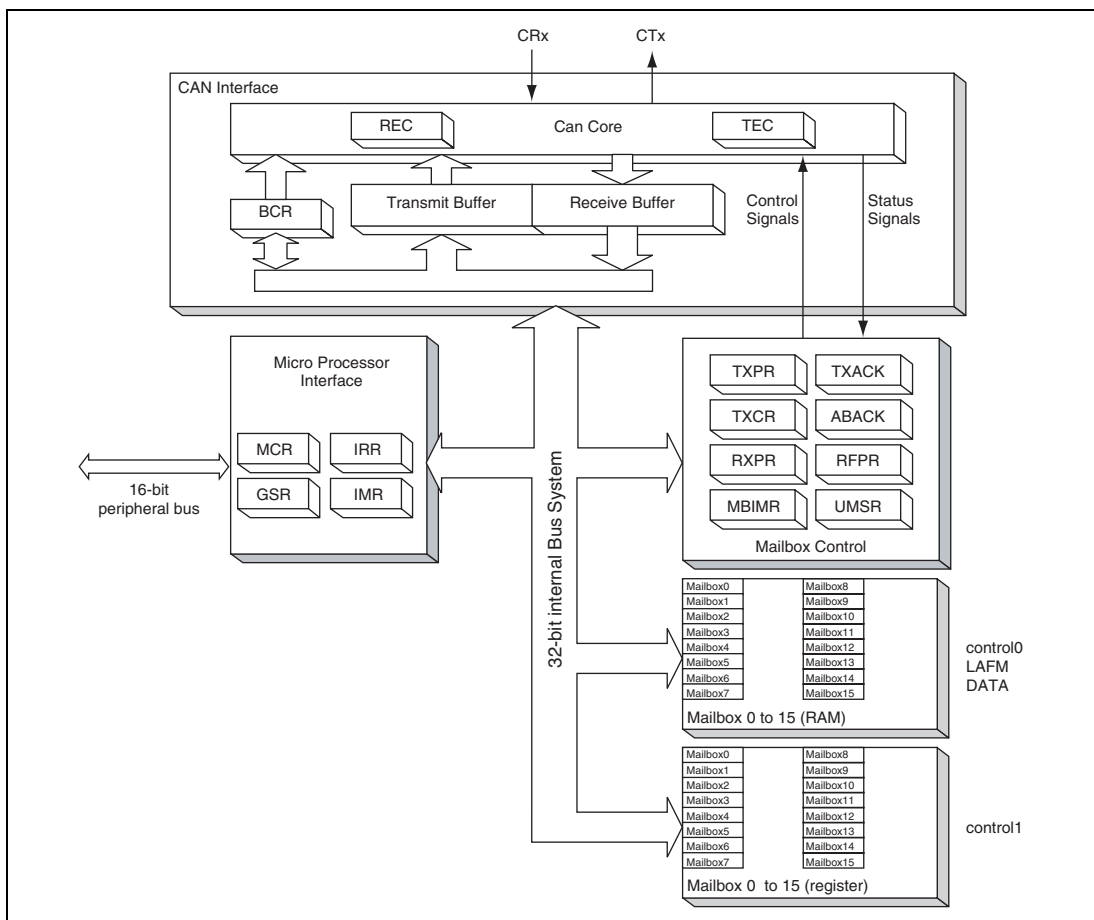

Figure 13.1 RCAN-ET Architecture

### 13.2.2 Important

Although core of RCAN-ET is designed based on a 32-bit bus system, the whole RCAN-ET including MPI for the CPU has 16-bit bus interface to CPU. In that case, LongWord (32-bit) access must be implemented as 2 consecutive word (16-bit) accesses. In this manual, LongWord access means the two consecutive accesses.

#### (1) Micro Processor Interface (MPI)

The MPI allows communication between the Renesas CPU and RCAN-ET's registers/mailboxes to control the memory interface. It also contains the Wakeup Control logic that detects the CAN bus activities and notifies the MPI and the other parts of RCAN-ET so that the RCAN-ET can automatically exit the Sleep mode.

It contains registers such as MCR, IRR, GSR and IMR.

#### (2) Mailbox

The Mailboxes consists of RAM configured as message buffers and registers. There are 16 Mailboxes, and each mailbox has the following information.

<RAM>

- CAN message control (identifier, rtr, ide,etc)
- CAN message data (for CAN Data frames)
- Local Acceptance Filter Mask for reception

<Registers>

- CAN message control (dlc)
- 3-bit wide Mailbox Configuration, Disable Automatic Re-Transmission bit, Auto-Transmission for Remote Request bit, New Message Control bit

### (3) Mailbox Control

The Mailbox Control handles the following functions:

- For received messages, compare the IDs and generate appropriate RAM addresses/data to store messages from the CAN Interface into the Mailbox and set/clear appropriate registers accordingly.
- To transmit messages, RCAN-ET will run the internal arbitration to pick the correct priority message, and load the message from the Mailbox into the Tx-buffer of the CAN Interface and set/clear appropriate registers accordingly.
- Arbitrates Mailbox accesses between the CPU and the Mailbox Control.
- Contains registers such as TXPR, TXCR, TXACK, ABACK, RXPR, RFPR, UMSR and MBIMR.

### (4) CAN Interface

This block conforms to the requirements for a CAN Bus Data Link Controller which is specified in Ref. [2, 4]. It fulfils all the functions of the Data Link Controller as specified by the OSI model. This functional entity also provides the registers and the logic which are specific to a given CAN bus, which includes the Receive Error Counter, Transmit Error Counter, the Bit Configuration Registers and various useful Test Modes. This block also contains functional entities to hold the data received and the data to be transmitted for the CAN Data Link Controller.

#### 13.2.3 Input/Output Pins

The table below lists the RCAN-ET input and output pins.

Channel	Name	Abbreviation	I/O	Function
0	Transmit data pin	CTx_0	Output	CAN-bus transmit pin
	Receive data pin	CRx_0	Input	CAN-bus receive pin

### 13.2.4 Memory Map

The diagram of the memory map is shown below.

**Figure 13.2 RCAN-ET Memory Map**

The locations not used (between H'000 and H'2F2) are reserved and cannot be accessed.

## 13.3 Mailbox

### 13.3.1 Mailbox Structure

Mailboxes play a role as message buffers to transmit/receive CAN frames. Each Mailbox is comprised of 3 identical storage fields that are 1): Message Control, 2): Local Acceptance Filter Mask, 3): Message Data. The following table shows the address map for the control, LAFM, data and addresses for each mailbox.

**Table 13.1 Address map for Each Mailbox**

Mailbox	Address			
	Control0 4 bytes	LAFM 4 bytes	Data 8 bytes	Control1 2 bytes
0 (Receive Only)	100 – 103	104 – 107	108 – 10F	110 – 111
1	120 – 123	124 – 127	128 – 12F	130 – 131
2	140 – 143	144 – 147	148 – 14F	150 – 151
3	160 – 163	164 – 167	168 – 16F	170 – 171
4	180 – 183	184 – 187	188 – 18F	190 – 191
5	1A0 – 1A3	1A4 – 1A7	1A8 – 1AF	1B0 – 1B1
6	1C0 – 1C3	1C4 – 1C7	1C8 – 1CF	1D0 – 1D1
7	1E0 – 1E3	1E4 – 1E7	1E8 – 1EF	1F0 – 1F1
8	200 – 203	204 – 207	208 – 20F	210 – 211
9	220 – 223	224 – 227	228 – 22F	230 – 231
10	240 – 243	244 – 247	248 – 24F	250 – 251
11	260 – 263	264 – 267	268 – 26F	270 – 271
12	280 – 283	284 – 287	288 – 28F	290 – 291
13	2A0 – 2A3	2A4 – 2A7	2A8 – 2AF	2B0 – 2B1
14	2C0 – 2C3	2C4 – 2C7	2C8 – 2CF	2D0 – 2D1
15	2E0 – 2E3	2E4 – 2E7	2E8 – 2EF	2F0 – 2F1

Mailbox-0 is a receive-only box, and all the other Mailboxes can operate as both receive and transmit boxes, dependant upon the MBC (Mailbox Configuration) bits in the Message Control. The following diagram shows the structure of a Mailbox in detail.

**Table 13.2 Roles of Mailboxes**

	<b>Tx</b>	<b>Rx</b>
MB15 to MB 1	OK	OK
MB0	—	OK

MB0 (reception MB)		Byte: 8-bit access, Word: 16-bit access, LW (LongWord): 32-bit access																Access Size	Field Name

Notes: 1. All bits shadowed in grey are reserved and must be written LOW. The value returned by a read may not always be '0' and should not be relied upon.  
2. MBC[1] is fixed to "1".  
3. ATX and DART are not supported by Mailbox-0, and the MBC setting of Mailbox-0 is limited.  
4. Since the initial value of the MCR15 bit is 1, the order of the message control and the bits STDID, RTR, IDE and EXTID in LAFM differs from that of HCAN2.

**Figure 13.3 Mailbox-N Structure**

### 13.3.2 Message Control Field

**STDID[10:0]:** These bits set the identifier (standard identifier) of data frames and remote frames.

**EXTID[17:0]:** These bits set the identifier (extended identifier) of data frames and remote frames.

**RTR** (Remote Transmission Request bit): Used to distinguish between data frames and remote frames. This bit is overwritten by received CAN Frames depending on Data Frames or Remote Frames.

**Important:** Please note that, when ATX bit is set with the setting MBC=001(bin), the RTR bit will never be set. When a Remote Frame is received, the CPU can be notified by the corresponding RFPR set or IRR[2] (Remote Frame Request Interrupt), however, as RCAN-ET needs to transmit the current message as a Data Frame, the RTR bit remains unchanged.

**Important:** In order to support automatic answer to remote frame when MBC=001(bin) is used and ATX=1, the RTR flag must be programmed to zero to allow data frame to be transmitted.

Note: When a Mailbox is configured to send a remote frame request, the DLC used for transmission is the one stored into the Mailbox.

RTR	Description
0	Data frame
1	Remote frame

**IDE** (Identifier Extension bit): Used to distinguish between the standard format and extended format of CAN data frames and remote frames.

IDE	Description
0	Standard format
1	Extended format

- Mailbox-0

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	NMC	0	0	MBC[2:0]			0	0	0	0	DLC[3:0]			
Initial value:	0	0	0	0	0	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R	R	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Note: MBC[1] of MB0 is always "1".

- Mailbox-15 to 1

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	NMC	ATX	DART	MBC[2:0]			0	0	0	0	DLC[3:0]			
Initial value:	0	0	0	0	0	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

**NMC (New Message Control):** When this bit is set to '0', the Mailbox of which the RXPR or RFPR bit is already set does not store the new message but maintains the old one and sets the UMSR correspondent bit. When this bit is set to '1', the Mailbox of which the RXPR or RFPR bit is already set overwrites with the new message and sets the UMSR correspondent bit.

**Important:** Please note that if a remote frame is overwritten with a data frame or vice versa could be that both RXPR and RFPR flags (together with UMSR) are set for the same Mailbox. In this case the RTR bit within the Mailbox Control Field should be relied upon.

NMC	Description
0	Overrun mode (Initial value)
1	Overwrite mode

**ATX (Automatic Transmission of Data Frame):** When this bit is set to '1' and a Remote Frame is received into the Mailbox DLC is stored. Then, a Data Frame is transmitted from the same Mailbox using the current contents of the message data and updated DLC by setting the corresponding TXPR automatically. The scheduling of transmission is still governed by ID priority or Mailbox priority as configured with the Message Transmission Priority control bit (MCR.2). In order to use this function, MBC[2:0] needs to be programmed to be '001' (Bin). When a transmission is performed by this function, the DLC (Data Length Code) to be used is the one that has been received. Application needs to guarantee that the DLC of the remote frame correspond to the DLC of the data frame requested.

**Important:** When ATX is used and MBC=001 (Bin) the filter for the IDE bit cannot be used since ID of remote frame has to be exactly the same as that of data frame as the reply message.

**Important:** Please note that, when this function is used, the RTR bit will never be set despite receiving a Remote Frame. When a Remote Frame is received, the CPU will be notified by the corresponding RFPR set, however, as RCAN-ET needs to transmit the current message as a Data Frame, the RTR bit remains unchanged.

**Important:** Please note that in case of overrun condition (UMSR flag set when the Mailbox has its NMC=0), the message received is discarded. In case a remote frame is causing overrun into a Mailbox configured with ATX=1, a request to automatically transmit the corresponding message may be accepted.

ATX	Description
0	Automatic Transmission of Data Frame disabled (Initial value)
1	Automatic Transmission of Data Frame enabled

**DART (Disable Automatic Re-Transmission):** When this bit is set, it disables the automatic re-transmission of a message in the event of an error on the CAN bus or an arbitration lost on the CAN bus. In effect, when this function is used, the corresponding TXCR bit is automatically set at the start of transmission. When this bit is set to '0', RCAN-ET tries to transmit the message as many times as required until it is successfully transmitted or it is cancelled by the TXCR.

DART	Description
0	Re-transmission enabled (Initial value)
1	Re-Transmission disabled

**MBC[2:0] (Mailbox Configuration):** These bits configure the nature of each Mailbox as follows. When MBC=111 (Bin), the Mailbox is inactive, i.e., it does not receive or transmit a message regardless of TXPR or other settings. The MBC='110', '101' and '100' settings are prohibited. When the MBC is set to any other value, the LAFM field becomes available. Please don't set TXPR when MBC is set as reception. There is no hardware protection, and TXPR remains set. MBC[1] of Mailbox-0 is fixed to "1" by hardware.

**Table 13.3 Mailbox Function Setting**

MBC[2]	MBC[1]	MBC[0]	Data Frame Transmit	Remote Frame Transmit	Data Frame Receive	Remote Frame Receive	Remarks	
0	0	0	Yes	Yes	No	No	<ul style="list-style-type: none"> <li>Not allowed for Mailbox-0</li> </ul>	
0	0	1	Yes	Yes	No	Yes	<ul style="list-style-type: none"> <li>Can be used with ATX*</li> <li>Not allowed for Mailbox-0</li> <li>LAFM can be used</li> </ul>	
0	1	0	No	No	Yes	Yes	<ul style="list-style-type: none"> <li>Allowed for Mailbox-0</li> <li>LAFM can be used</li> </ul>	
0	1	1	No	No	Yes	No	<ul style="list-style-type: none"> <li>Allowed for Mailbox-0</li> <li>LAFM can be used</li> </ul>	
1	0	0	Setting prohibited					
1	0	1	Setting prohibited					
1	1	0	Setting prohibited					
1	1	1	Mailbox inactive (Initial value)					

Notes: \* In order to support automatic retransmission, RTR shall be "0" when MBC=001 (bin) and ATX=1.

When ATX=1 is used, the filter for IDE must not be used

**DLC[3:0] (Data Length Code):** These bits encode the number of data bytes from 0, 1, 2, ... 8 that will be transmitted in a data frame. Please note that when a remote frame request is transmitted the DLC value to be used must be the same as the DLC of the data frame that is requested.

DLC[3]	DLC[2]	DLC[1]	DLC[0]	Description
0	0	0	0	Data Length = 0 bytes (Initial value)
0	0	0	1	Data Length = 1 byte
0	0	1	0	Data Length = 2 bytes
0	0	1	1	Data Length = 3 bytes
0	1	0	0	Data Length = 4 bytes
0	1	0	1	Data Length = 5 bytes
0	1	1	0	Data Length = 6 bytes
0	1	1	1	Data Length = 7 bytes
1	x	x	x	Data Length = 8 bytes

### 13.3.3 Local Acceptance Filter Mask (LAFM)

When MBC is set to 001, 010, 011 (Bin), this field is used as LAFM Field. The LAFM allows a Mailbox to accept more than one identifier. The LAFM is comprised of two 16-bit read/write areas as shown figure 13.4.

Register Name	Address	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Access Size	Field Name
MB[0].LAFMH	H'104 + N*32	IDE LAFM	0	0	STDID_LAFM[10:0]											EXTID LAFM[17:16]	Word/LW	LAFM Field	
MB[0].LAFML	H'106 + N*32	EXTID_LAFM[15:0]											Word						

**Figure 13.4 Acceptance Filter**

If a bit is set in the LAFM, then the corresponding bit of a received CAN identifier is ignored when the RCAN-ET searches a Mailbox with the matching CAN identifier. If the bit is cleared, then the corresponding bit of a received CAN identifier must match to the STDID/IDE/EXTID set in the mailbox to be stored. The structure of the LAFM is same as the message control in a Mailbox. If this function is not required, it must be filled with '0'.

**Important:** RCAN-ET starts to find a matching identifier from Mailbox-15 down to Mailbox-0. As soon as RCAN-ET finds one matching, it stops the search. The message will be stored or not depending on the NMC and RXPR/RFPR flags. This means that, even using LAFM, a received message can only be stored into 1 Mailbox.

**Important:** When a message is received and a matching Mailbox is found, the whole message is stored into the Mailbox. This means that, if the LAFM is used, the STDID, RTR, IDE and EXTID may differ to the ones originally set as they are updated with the STDID, RTR, IDE and EXTID of the received message.

**STD\_LAFM[10:0]** — Filter mask bits for the CAN base identifier [10:0] bits.

STD_LAFM[10:0]	Description
0	Corresponding STD_ID bit is cared
1	Corresponding STD_ID bit is "don't cared"

**EXT\_LAFM[17:0]** — Filter mask bits for the CAN Extended identifier [17:0] bits.

<b>EXT_LAFM[17:0]</b>	<b>Description</b>
0	Corresponding EXT_ID bit is cared
1	Corresponding EXT_ID bit is "don't cared"

---

**IDE\_LAFM** — Filter mask bit for the CAN IDE bit.

<b>IDE_LAFM</b>	<b>Description</b>
0	Corresponding IDE_ID bit is cared
1	Corresponding IDE_ID bit is "don't cared"

---

### 13.3.4 Message Data Fields

Storage for the CAN message data that is transmitted or received. MSG\_DATA[0] corresponds to the first data byte that is transmitted or received. The bit order on the CAN bus is bit 7 through to bit 0.

## 13.4 RCAN-ET Control Registers

The following sections describe RCAN-ET control registers. The address is mapped as follow.

**Important:** These registers can only be accessed in Word size (16-bit).

**Table 13.4 RCAN-ET Control Registers Configuration**

Description	Address	Name	Access Size (bits)
Master Control Register	000	MCR	Word
General Status Register	002	GSR	Word
Bit Configuration Register 1	004	BCR1	Word
Bit Configuration Register 0	006	BCR0	Word
Interrupt Request Register	008	IRR	Word
Interrupt Mask Register	00A	IMR	Word
Transmit Error Counter/ Receive Error Counter	00C	TEC/REC	Word

### 13.4.1 Master Control Register (MCR)

The Master Control Register (MCR) is a 16-bit read/write register that controls RCAN-ET.

- MCR (Address = H'000)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MCR15	MCR14	—	—	—	TST[2:0]			MCR7	MCR6	MCR5	—	—	MCR2	MCR1	MCR0
Initial value:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W

**Bit 15 — ID Reorder (MCR15):** This bit changes the order of STDID, RTR, IDE and EXTID of both message control and LAFM.

Bit15: MCR15	Description
0	RCAN-ET is the same as HCAN2
1	RCAN-ET is not the same as HCAN2 (Initial value)

MCR15 (ID Reorder) = 0																		
Address	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Access Size	Field Name
H'100 + N*32	0	STDID[10:0]										RTR	IDE	EXTID[17:16]		Word/LW	Control 0	
H'102 + N*32	EXTID[15:0]															Word		
H'104 + N*32	0	STDID_LAFM[10:0]										0	IDE_LAFM	EXTID_LAFM [17:16]		Word/LW	LAFM Field	
H'106 + N*32	EXTID_LAFM[15:0]															Word		

MCR15 (ID Reorder) = 1																		
Address	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Access Size	Field Name
H'100 + N*32	IDE	RTR	0	STDID[10:0]										EXTID[17:16]		Word/LW	Control 0	
H'102 + N*32	EXTID[15:0]															Word		
H'104 + N*32	IDE_LAFM	0	0	STDID_LAFM[10:0]										EXTID_LAFM [17:16]		Word/LW	LAFM Field	
H'106 + N*32	EXTID_LAFM[15:0]															Word		

Figure 13.5 ID Reorder

This bit can be modified only in reset mode.

**Bit 14 — Auto Halt Bus Off (MCR14):** If both this bit and MCR6 are set, MCR1 is automatically set as soon as RCAN-ET enters Bus Off.

Bit14: MCR14	Description
0	RCAN-ET remains in Bus Off for normal recovery sequence (128 x 11 Recessive Bits) (Initial value)
1	RCAN-ET moves directly into Halt Mode after it enters Bus Off if MCR6 is set.

This bit can be modified only in reset mode.

**Bit 13 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 12 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 11 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 10 - 8 — Test Mode (TST[2:0]):** This bit enables/disables the test modes. Please note that before activating the Test Mode it is requested to move RCAN-ET into Halt mode or Reset mode. This is to avoid that the transition to Test Mode could affect a transmission/reception in progress. For details, please refer to section 13.6.2, Test Mode Settings.

Please note that the test modes are allowed only for diagnosis and tests and not when RCAN-ET is used in normal operation.

<b>Bit10: TST2</b>	<b>Bit9: TST1</b>	<b>Bit8: TST0</b>	<b>Description</b>
0	0	0	Normal Mode (initial value)
0	0	1	Listen-Only Mode (Receive-Only Mode)
0	1	0	Self Test Mode 1 (External)
0	1	1	Self Test Mode 2 (Internal)
1	0	0	Write Error Counter
1	0	1	Error Passive Mode
1	1	0	Setting prohibited
1	1	1	Setting prohibited

**Bit 7 — Auto-wake Mode (MCR7):** MCR7 enables or disables the Auto-wake mode. If this bit is set, the RCAN-ET automatically cancels the sleep mode (MCR5) by detecting CAN bus activity (dominant bit). If MCR7 is cleared the RCAN-ET does not automatically cancel the sleep mode.

RCAN-ET cannot store the message that wakes it up.

Note: MCR7 cannot be modified while in sleep mode.

<b>Bit7: MCR7</b>	<b>Description</b>
0	Auto-wake by CAN bus activity disabled (Initial value)
1	Auto-wake by CAN bus activity enabled

**Bit 6 — Halt during Bus Off (MCR6):** MCR6 enables or disables entering Halt mode immediately when MCR1 is set during Bus Off. This bit can be modified only in Reset or Halt mode. Please note that when Halt is entered in Bus Off the CAN engine is also recovering immediately to Error Active mode.

Bit6: MCR6	Description
0	If MCR[1] is set, RCAN-ET will not enter Halt mode during Bus Off but wait up to end of recovery sequence. (initial value)
1	Enter Halt mode immediately during Bus Off if MCR[1] or MCR[14] are asserted.

**Bit 5 — Sleep Mode (MCR5):** Enables or disables Sleep mode transition. If this bit is set, while RCAN-ET is in halt mode, the transition to sleep mode is enabled. Setting MCR5 is allowed after entering Halt mode. The two Error Counters (REC, TEC) will remain the same during Sleep mode. This mode will be exited in two ways:

1. by writing a '0' to this bit position,
2. or, if MCR[7] is enabled, after detecting a dominant bit on the CAN bus.

If Auto wake up mode is disabled, RCAN-ET will ignore all CAN bus activities until the sleep mode is terminated. When leaving this mode the RCAN-ET will synchronise to the CAN bus (by checking for 11 recessive bits) before joining CAN Bus activity. This means that, when the No.2 method is used, RCAN-ET will miss the first message to receive. CAN transceivers stand-by mode will also be unable to cope with the first message when exiting stand by mode, and the S/W needs to be designed in this manner.

In sleep mode only the following registers can be accessed: MCR, GSR, IRR and IMR.

**Important:** RCAN-ET is required to be in Halt mode before requesting to enter in Sleep mode. That allows the CPU to clear all pending interrupts before entering sleep mode. Once all interrupts are cleared RCAN-ET must leave the Halt mode and enter Sleep mode simultaneously (by writing MCR[5]=1 and MCR[1]=0 at the same time).

Bit 5: MCR5	Description
0	RCAN-ET sleep mode released (Initial value)
1	Transition to RCAN-ET sleep mode enabled

**Bit 4 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 3 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 2 — Message Transmission Priority (MCR2):** MCR2 selects the order of transmission for pending transmit data. If this bit is set, pending transmit data are sent in order of the bit position in the Transmission Pending Register (TXPR). The order of transmission starts from Mailbox-15 as the highest priority, and then down to Mailbox-1 (if those mailboxes are configured for transmission).

If MCR2 is cleared, all messages for transmission are queued with respect to their priority (by running internal arbitration). The highest priority message has the Arbitration Field (STDID + IDE bit + EXTID (if IDE=1) + RTR bit) with the lowest digital value and is transmitted first. The internal arbitration includes the RTR bit and the IDE bit (internal arbitration works in the same way as the arbitration on the CAN Bus between two CAN nodes starting transmission at the same time).

This bit can be modified only in Reset or Halt mode.

Bit 2: MCR2	Description
0	Transmission order determined by message identifier priority (Initial value)
1	Transmission order determined by mailbox number priority (Mailbox-15 → Mailbox-1)

**Bit 1—Halt Request (MCR1):** Setting the MCR1 bit causes the CAN controller to complete its current operation and then enter Halt mode (where it is cut off from the CAN bus). The RCAN-ET remains in Halt Mode until the MCR1 is cleared. During the Halt mode, the CAN Interface does not join the CAN bus activity and does not store messages or transmit messages. All the user registers (including Mailbox contents and TEC/REC) remain unchanged with the exception of IRR0 and GSR4 which are used to notify the halt status itself. If the CAN bus is in idle or intermission state regardless of MCR6, RCAN-ET will enter Halt Mode within one Bit Time. If MCR6 is set, a halt request during Bus Off will be also processed within one Bit Time. Otherwise the full Bus Off recovery sequence will be performed beforehand. Entering the Halt Mode can be notified by IRR0 and GSR4.

If both MCR14 and MCR6 are set, MCR1 is automatically set as soon as RCAN-ET enters Bus Off.

In the Halt mode, the RCAN-ET configuration can be modified with the exception of the Bit Timing setting, as it does not join the bus activity. MCR[1] has to be cleared by writing a '0' in order to re-join the CAN bus. After this bit has been cleared, RCAN-ET waits until it detects 11 recessive bits, and then joins the CAN bus.

Note: After issuing a Halt request the CPU is not allowed to set TXPR or TXCR or clear MCR1 until the transition to Halt mode is completed (notified by IRR0 and GSR4). After MCR1 is set this can be cleared only after entering Halt mode or through a reset operation (SW or HW).

Note: Transition into or recovery from HALT mode, is only possible if the BCR1 and BCR0 registers are configured to a proper Baud Rate.

Bit 1: MCR1	Description
0	Clear Halt request (Initial value)
1	Halt mode transition request

**Bit 0 — Reset Request (MCR0):** Controls resetting of the RCAN-ET module. When this bit is changed from '0' to '1' the RCAN-ET controller enters its reset routine, re-initialising the internal logic, which then sets GSR3 and IRR0 to notify the reset mode. All user registers are initialised.

RCAN-ET can be re-configured while this bit is set. This bit has to be cleared by writing a '0' to join the CAN bus. After this bit is cleared, the RCAN-ET module waits until it detects 11 recessive bits, and then joins the CAN bus. The Baud Rate needs to be set up to a proper value in order to sample the value on the CAN Bus.

After Power On Reset, this bit and GSR3 are always set. This means that a reset request has been made and RCAN-ET needs to be configured.

The Reset Request is equivalent to a Power On Reset but controlled by Software.

Bit 0: MCR0	Description
0	Clear Reset request
1	CAN Interface reset mode transition request (Initial value)

### 13.4.2 General Status Register (GSR)

The General Status Register (GSR) is a 16-bit read-only register that indicates the status of RCAN-ET.

- GSR (Address = H'002)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	GSR5	GSR4	GSR3	GSR2	GSR1	GSR0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

**Bits 15 to 6: Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 5 — Error Passive Status Bit (GSR5):** Indicates whether the CAN Interface is in Error Passive or not. This bit will be set high as soon as the RCAN-ET enters the Error Passive state and is cleared when the module enters again the Error Active state (this means the GSR5 will stay high during Error Passive and during Bus Off). Consequently to find out the correct state both GSR5 and GSR0 must be considered.

Bit 5: GSR5	Description
0	RCAN-ET is not in Error Passive or in Bus Off status (Initial value) [Reset condition] RCAN-ET is in Error Active state
1	RCAN-ET is in Error Passive (if GSR0=0) or Bus Off (if GSR0=1) [Setting condition] When $TEC \geq 128$ or $REC \geq 128$ , or error passive test mode is selected

**Bit 4 — Halt/Sleep Status Bit (GSR4):** Indicates whether the CAN engine is in the halt/sleep state or not. Please note that the clearing time of this flag is not the same as the setting time of IRR12.

Please note that this flag reflects the status of the CAN engine and not of the full RCAN-ET IP. RCAN-ET exits sleep mode and can be accessed once MCR5 is cleared. The CAN engine exits sleep mode only after two additional transmission clocks on the CAN Bus.

Bit 4: GSR4	Description
0	RCAN-ET is not in the Halt state or Sleep state (Initial value)
1	Halt mode (if MCR1=1) or Sleep mode (if MCR5=1) [Setting condition] If MCR1 is set and the CAN bus is either in intermission or idle or MCR5 is set and RCAN-ET is in the halt mode or RCAN-ET is moving to Bus Off when MCR14 and MCR6 are both set

**Bit 3 — Reset Status Bit (GSR3):** Indicates whether the RCAN-ET is in the reset state or not.

Bit 3: GSR3	Description
0	RCAN-ET is not in the reset state
1	Reset state (Initial value) [Setting condition] After an RCAN-ET internal reset (due to SW or HW reset)

**Bit 2 — Message Transmission in progress Flag (GSR2):** Flag that indicates to the CPU if the RCAN-ET is in Bus Off or transmitting a message or an error/overload flag due to error detected during transmission. The timing to set TXACK is different from the time to clear GSR2. TXACK is set at the 7<sup>th</sup> bit of End Of Frame. GSR2 is set at the 3<sup>rd</sup> bit of intermission if there are no more messages ready to be transmitted. It is also set by arbitration lost, bus idle, reception, reset or halt transition.

Bit 2: GSR2	Description
0	RCAN-ET is in Bus Off or a transmission is in progress
1	[Setting condition] Not in Bus Off and no transmission in progress (Initial value)

**Bit 1—Transmit/Receive Warning Flag (GSR1):** Flag that indicates an error warning.

Bit 1: GSR1	Description
0	[Reset condition] When (TEC < 96 and REC < 96) or Bus Off (Initial value)
1	[Setting condition] When $96 \leq \text{TEC} < 256$ or $96 \leq \text{REC} < 256$

Note: REC is incremented during Bus Off to count the recurrences of 11 recessive bits as requested by the Bus Off recovery sequence. However the flag GSR1 is not set in Bus Off.

**Bit 0—Bus Off Flag (GSR0):** Flag that indicates that RCAN-ET is in the bus off state.

Bit 0: GSR0	Description
0	[Reset condition] Recovery from bus off state or after a HW or SW reset (Initial value)
1	[Setting condition] When $\text{TEC} \geq 256$ (bus off state)

Note: Only the lower 8 bits of TEC are accessible from the user interface. The 9<sup>th</sup> bit is equivalent to GSR0.

### 13.4.3 Bit Configuration Register (BCR0, BCR1)

The bit configuration registers (BCR0 and BCR1) are 2 X 16-bit read/write register that are used to set CAN bit timing parameters and the baud rate pre-scaler for the CAN Interface.

The Time quanta is defined as:

$$\text{Time quanta} = \frac{2 * \text{BRP}}{f_{\text{clk}}}$$

Where: BRP (Baud Rate Pre-scaler) is the value stored in BCR0 incremented by 1 and fclk is the used peripheral bus frequency.

- BCR1 (Address = H'004)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG1[3:0]			—	TSG2[2:0]			—	—	SJW[1:0]		—	—	—	BSP	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R/W

Please refer to the table below for TSG1 and TSG2 setting.

**Bits 15 to 12 — Time Segment 1 (TSG1[3:0] = BCR1[15:12]):** These bits are used to set the segment TSEG1 (=PRSEG + PHSEG1) to compensate for edges on the CAN Bus with a positive phase error. A value from 4 to 16 time quanta can be set.

**Bit 15: Bit 14: Bit 13: Bit 12:**  
**TSG1[3] TSG1[2] TSG1[1] TSG1[0] Description**

0	0	0	0	Setting prohibited (Initial value)
0	0	0	1	Setting prohibited
0	0	1	0	Setting prohibited
0	0	1	1	PRSEG + PHSEG1 = 4 time quanta
0	1	0	0	PRSEG + PHSEG1 = 5 time quanta
:	:	:	:	:
:	:	:	:	:
1	1	1	1	PRSEG + PHSEG1 = 16 time quanta

**Bit 11: Reserved.** The written value should always be '0' and the returned value is '0'.

**Bits 10 to 8 — Time Segment 2 (TSG2[2:0] = BCR1[10:8]):** These bits are used to set the segment TSEG2 (=PHSEG2) to compensate for edges on the CAN Bus with a negative phase error. A value from 2 to 8 time quanta can be set as shown below.

Bit 10: TSG2[2]	Bit 9: TSG2[1]	Bit 8: TSG2[0]	Description
0	0	0	Setting prohibited (Initial value)
0	0	1	PHSEG2 = 2 time quanta (conditionally prohibited) See the table below for TSG1 and TSG2 setting.
0	1	0	PHSEG2 = 3 time quanta
0	1	1	PHSEG2 = 4 time quanta
1	0	0	PHSEG2 = 5 time quanta
1	0	1	PHSEG2 = 6 time quanta
1	1	0	PHSEG2 = 7 time quanta
1	1	1	PHSEG2 = 8 time quanta

**Bits 7 and 6: Reserved.** The written value should always be '0' and the returned value is '0'.

**Bits 5 and 4 - ReSynchronisation Jump Width (SJW[1:0] = BCR0[5:4]):** These bits set the synchronisation jump width.

Bit 5: SJW[1]	Bit 4: SJW[0]	Description
0	0	Synchronisation Jump width = 1 time quantum (Initial value)
0	1	Synchronisation Jump width = 2 time quanta
1	0	Synchronisation Jump width = 3 time quanta
1	1	Synchronisation Jump width = 4 time quanta

**Bits 3 to 1 Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 0 — Bit Sample Point (BSP = BCR1[0]):** Sets the point at which data is sampled.

Bit 0: BSP	Description
0	Bit sampling at one point (end of time segment 1) (Initial value)
1	Bit sampling at three points (rising edge of the last three clock cycles of PHSEG1)

- BCR0 (Address = H'006)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	BRP[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

**Bits 8 to 15 : Reserved.** The written value should always be '0' and the returned value is '0'.

**Bits 7 to 0—Baud Rate Pre-scale (BRP[7:0] = BCR0 [7:0]):** These bits are used to define the peripheral bus clock periods contained in a Time Quantum.

Bit 7: BRP[7]	Bit 6: BRP[6]	Bit 5: BRP[5]	Bit 4: BRP[4]	Bit 3: BRP[3]	Bit 2: BRP[2]	Bit 1: BRP[1]	Bit 0: BRP[0]	Description
0	0	0	0	0	0	0	0	2 X peripheral bus clock (Initial value)
0	0	0	0	0	0	0	1	4 X peripheral bus clock
0	0	0	0	0	0	1	0	6 X peripheral bus clock
:	:	:	:	:	:	:	:	2*(register value+1) X peripheral bus clock
1	1	1	1	1	1	1	1	512 X peripheral bus clock

- Requirements of Bit Configuration Register

**SYNC\_SEG:** Segment for establishing synchronisation of nodes on the CAN bus. (Normal bit edge transitions occur in this segment.)

**PRSEG:** Segment for compensating for physical delay between networks.

**PHSEG1:** Buffer segment for correcting phase drift (positive). (This segment is extended when synchronisation (resynchronisation) is established.)

**PHSEG2:** Buffer segment for correcting phase drift (negative). (This segment is shortened when synchronisation (resynchronisation) is established)

**TSEG1:** TSG1 + 1

**TSEG2:** TSG2 + 1

The RCAN-ET Bit Rate Calculation is:

$$\text{Bit Rate} = f_{\text{CLK}} / \{2 \times (\text{BRP} + 1) \times (\text{TSEG1} + \text{TSEG2} + 1)\}$$

where BRP is given by  $2 \times \text{register value} + 1$ , TSEG1 and TSEG2 are derived values from the descriptions of the following table. The time segment '+ 1' in the above formula is for the Sync-Seg whose duration is 1 time quanta.

$$f_{\text{CLK}} = \text{Peripheral Clock}$$

#### BCR Setting Constraints

$$\text{TSEG1}_{\text{min}} > \text{TSEG2} \geq \text{SJW}_{\text{max}} \quad (\text{SJW} = 1 \text{ to } 4)$$

$$8 \leq \text{TSEG1} + \text{TSEG2} + 1 \leq 25 \text{ time quanta} \quad (\text{TSEG1} + \text{TSEG2} + 1 = 7 \text{ is not allowed})$$

$$\text{TSEG2} \geq 2$$

These constraints allow the setting range shown in the table below for TSEG1 and TSEG2 in the Bit Configuration Register. The number in the table shows possible setting of SJW. "No" shows that there is no allowed combination of TSEG1 and TSEG2.

**Table 13.5 TSG and TSEG Setting**

		001	010	011	100	101	110	111	TSG2
		2	3	4	5	6	7	8	TSEG2
TSG1	TSEG1								
0011	4	No	1-3	No	No	No	No	No	No
0100	5	1-2	1-3	1-4	No	No	No	No	No
0101	6	1-2	1-3	1-4	1-4	No	No	No	No
0110	7	1-2	1-3	1-4	1-4	1-4	No	No	No
0111	8	1-2	1-3	1-4	1-4	1-4	1-4	No	No
1000	9	1-2	1-3	1-4	1-4	1-4	1-4	1-4	1-4
1001	10	1-2	1-3	1-4	1-4	1-4	1-4	1-4	1-4
1010	11	1-2	1-3	1-4	1-4	1-4	1-4	1-4	1-4
1011	12	1-2	1-3	1-4	1-4	1-4	1-4	1-4	1-4
1100	13	1-2	1-3	1-4	1-4	1-4	1-4	1-4	1-4
1101	14	1-2	1-3	1-4	1-4	1-4	1-4	1-4	1-4
1110	15	1-2	1-3	1-4	1-4	1-4	1-4	1-4	1-4
1111	16	1-2	1-3	1-4	1-4	1-4	1-4	1-4	1-4

Example: To have a Bit rate of 250 Kbps with a frequency of fclk = 25 MHz, it is possible to set: BRP = 4, TSEG1 = 5, TSEG2 = 4. Then the configuration to write is BCR1 = 4300 and BCR0 = 0004.

Example: To have a Bit rate of 500 Kbps with a frequency of fclk = 20 MHz, it is possible to set: BRP = 1, TSEG1 = 6, TSEG2 = 3. Then the configuration to write is BCR1 = 5200 and BCR0 = 0001.

### 13.4.4 Interrupt Request Register (IRR)

The interrupt register (IRR) is a 16-bit read/write-clearable register containing status flags for the various interrupt sources.

- IRR (Address = H'008)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	IRR13	IRR12	—	—	IRR9	IRR8	IRR7	IRR6	IRR5	IRR4	IRR3	IRR2	IRR1	IRR0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W

**Bits 15 to 14: Reserved.**

**Bit 13 - Message Error Interrupt (IRR13):** this interrupt indicates that:

- A message error has occurred when in test mode.
- Note: If a Message Overload condition occurs when in Test Mode, then this bit will not be set. When not in test mode this interrupt is inactive.

Bit 13: IRR13	Description
0	Message error has not occurred in test mode (Initial value) [Clearing condition] Writing 1  (When the CPU is used to clear this flag by writing 1 while the corresponding interrupt is enabled, be sure to read the flag after writing 1 to it.)
1	[Setting condition] message error has occurred in test mode

**Bit 12 – Bus Activity while in Sleep Mode (IRR12):** IRR12 indicates that a CAN bus activity is present. While the RCAN-ET is in sleep mode and a dominant bit is detected on the CAN bus, this bit is set. This interrupt is cleared by writing a '1' to this bit position. Writing a '0' has no effect. If auto wakeup is not used and this interrupt is not requested it needs to be disabled by the related interrupt mask register. If auto wake up is not used and this interrupt is requested it should be cleared only after recovering from sleep mode. This is to avoid that a new falling edge of the reception line causes the interrupt to get set again.

Please note that the setting time of this interrupt is different from the clearing time of GSR4.

Bit 12: IRR12	Description
0	bus idle state (Initial value) [Clearing condition] Writing 1 (When the CPU is used to clear this flag by writing 1 while the corresponding interrupt is enabled, be sure to read the flag after writing 1 to it.)
1	[Setting condition] dominant bit level detection on the Rx line while in sleep mode

### Bits 11 to 10: Reserved

**Bit 9 – Message Overrun/Overwrite Interrupt Flag (IRR9):** Flag indicating that a message has been received but the existing message in the matching Mailbox has not been read as the corresponding RXPR or RFPR is already set to '1' and not yet cleared by the CPU. Thus the received message is either abandoned (overrun) or overwritten dependant upon the NMC (New Message Control) bit. This bit is cleared when all bit in UMSR (Unread Message Status Register) are cleared (by writing '1') or by setting MBIMR (MailBox interrupt Mast Register) for all UMSR flag set . It is also cleared by writing a '1' to all the correspondent bit position in MBIMR. Writing to this bit position has no effect.

Bit 9: IRR9	Description
0	No pending notification of message overrun/overwrite [Clearing condition] Clearing of all bit in UMSR/setting MBIMR for all UMSR set (initial value)
1	A receive message has been discarded due to overrun condition or a message has been overwritten [Setting condition] Message is received while the corresponding RXPR and/or RFPR =1 and MBIMR =0

**Bit 8 - Mailbox Empty Interrupt Flag (IRR8):** This bit is set when one of the messages set for transmission has been successfully sent (corresponding TXACK flag is set) or has been successfully aborted (ABACK flag corresponding to the message whose transmission cancel has been executed is set). The related TXPR is also cleared and this mailbox is now ready to accept a new message data for the next transmission. In effect, this bit is set by an OR'ed signal of the TXACK and ABACK bits not masked by the corresponding MBIMR flag. Therefore, this bit is automatically cleared when all the TXACK and ABACK bits are cleared. It is also cleared by writing a '1' to all the correspondent bit position in MBIMR. Writing to this bit position has no effect.

<b>Bit 8: IRR8</b>	<b>Description</b>
0	Messages set for transmission or transmission cancellation request NOT progressed. (Initial value)  [Clearing Condition] All the TXACK and ABACK bits are cleared/setting MBIMR for all TXACK and ABACK set
1	Message has been transmitted or aborted (cancelled), and new message can be stored  [Setting condition]  When a TXACK or ABACK bit is set (if MBIMR=0).

**Bit 7 - Overload Frame (IRR7):** Flag indicating that the RCAN-ET has detected the transmission of an overload frame. IRR7 is cleared by writing a '1' to this bit position; writing a '0' has no effect.

<b>Bit 7: IRR7</b>	<b>Description</b>
0	[Clearing condition] Writing 1 (Initial value)  (When the CPU is used to clear this flag by writing 1 while the corresponding interrupt is enabled, be sure to read the flag after writing 1 to it.)
1	[Setting conditions] Overload condition detected

**Bit 6 - Bus Off Interrupt Flag (IRR6):** This bit is set when RCAN-ET enters the Bus-off state or when RCAN-ET leaves Bus-off and returns to Error-Active. The cause therefore is the existing condition  $TEC \geq 256$  at the node or the end of the Bus-off recovery sequence (128X11 consecutive recessive bits) or the transition from Bus Off to Halt (automatic or manual). This bit remains set even if the RCAN-ET node leaves the bus-off condition, and needs to be explicitly cleared by S/W. The S/W is expected to read the GSR0 to judge whether RCAN-ET is in the bus-off or error active status. It is cleared by writing a '1' to this bit position even if the node is still bus-off. Writing a '0' has no effect.

Bit 6: IRR6	Description
0	[Clearing condition] Writing 1 (Initial value) (When the CPU is used to clear this flag by writing 1 while the corresponding interrupt is enabled, be sure to read the flag after writing 1 to it.)
1	Enter Bus off state caused by transmit error or Error Active state returning from Bus-off  [Setting condition] When $TEC \geq 256$ or End of Bus-off after 128X11 consecutive recessive bits or transition from Bus Off to Halt

**Bit 5 - Error Passive Interrupt Flag (IRR5):** Interrupt flag indicating the error passive state caused by the transmit or receive error counter or by Error Passive forced by test mode. This bit is reset by writing a '1' to this bit position, writing a '0' has no effect. If this bit is cleared the node may still be error passive. Please note that the SW needs to check GSR0 and GSR5 to judge whether RCAN-ET is in Error Passive or Bus Off status.

Bit 5: IRR5	Description
0	[Clearing condition] Writing 1 (Initial value) (When the CPU is used to clear this flag by writing 1 while the corresponding interrupt is enabled, be sure to read the flag after writing 1 to it.)
1	Error passive state caused by transmit/receive error  [Setting condition] When $TEC \geq 128$ or $REC \geq 128$ or Error Passive test mode is used

**Bit 4 - Receive Error Counter Warning Interrupt Flag (IRR4):** This bit becomes set if the receive error counter (REC) reaches a value greater than 95 when RCAN-ET is not in the Bus Off status. The interrupt is reset by writing a '1' to this bit position, writing '0' has no effect.

Bit 4: IRR4	Description
0	[Clearing condition] Writing 1 (Initial value) (When the CPU is used to clear this flag by writing 1 while the corresponding interrupt is enabled, be sure to read the flag after writing 1 to it.)
1	Error warning state caused by receive error [Setting condition] When $REC \geq 96$ and RCAN-ET is not in Bus Off

**Bit 3 - Transmit Error Counter Warning Interrupt Flag (IRR3):** This bit becomes set if the transmit error counter (TEC) reaches a value greater than 95. The interrupt is reset by writing a '1' to this bit position, writing '0' has no effect.

Bit 3: IRR3	Description
0	[Clearing condition] Writing 1 (Initial value) (When the CPU is used to clear this flag by writing 1 while the corresponding interrupt is enabled, be sure to read the flag after writing 1 to it.)
1	Error warning state caused by transmit error [Setting condition] When $TEC \geq 96$

**Bit 2 - Remote Frame Request Interrupt Flag (IRR2):** flag indicating that a remote frame has been received in a mailbox. This bit is set if at least one receive mailbox, with related MBIMR not set, contains a remote frame transmission request. This bit is automatically cleared when all bits in the Remote Frame Receive Pending Register (RFPR), are cleared. It is also cleared by writing a '1' to all the correspondent bit position in MBIMR. Writing to this bit has no effect.

Bit 2: IRR2	Description
0	[Clearing condition] Clearing of all bits in RFPR (Initial value)
1	at least one remote request is pending [Setting condition] When remote frame is received and the corresponding MBIMR = 0

**Bit 1 – Data Frame Received Interrupt Flag (IRR1):** IRR1 indicates that there are pending Data Frames received. If this bit is set at least one receive mailbox contains a pending message. This bit is cleared when all bits in the Data Frame Receive Pending Register (RXPR) are cleared, i.e. there is no pending message in any receiving mailbox. It is in effect a logical OR of the RXPR flags from each configured receive mailbox with related MBIMR not set. It is also cleared by writing a '1' to all the correspondent bit position in MBIMR. Writing to this bit has no effect.

<b>Bit 1: IRR1</b>	<b>Description</b>
0	[Clearing condition] Clearing of all bits in RXPR (Initial value)
1	Data frame received and stored in Mailbox [Setting condition] When data is received and the corresponding MBIMR = 0

**Bit 0 – Reset/Halt/Sleep Interrupt Flag (IRR0):** This flag can get set for three different reasons. It can indicate that:

1. Reset mode has been entered after a SW (MCR0) or HW reset
2. Halt mode has been entered after a Halt request (MCR1)
3. Sleep mode has been entered after a sleep request (MCR5) has been made while in Halt mode.

The GSR may be read after this bit is set to determine which state RCAN-ET is in.

**Important:** When a Sleep mode request needs to be made, the Halt mode must be used beforehand. Please refer to the MCR5 description and Figure 13.8 - Halt Mode/Sleep Mode.

IRR0 is set by the transition from "0" to "1" of GSR3 or GSR4 or by transition from Halt mode to Sleep mode. So, IRR0 is not set if RCAN-ET enters Halt mode again right after exiting from Halt mode, without GSR4 being cleared. Similarly, IRR0 is not set by direct transition from Sleep mode to Halt Request. At the transition from Halt/Sleep mode to Transition/Reception, clearing GSR4 needs (one-bit time - TSEG2) to (one-bit time \* 2 - TSEG2).

In the case of Reset mode, IRR0 is set, however, the interrupt to the CPU is not asserted since IMR0 is automatically set by initialization.

<b>Bit 0: IRR0</b>	<b>Description</b>
0	[Clearing condition] Writing 1 (When the CPU is used to clear this flag by writing 1 while the corresponding interrupt is enabled, be sure to read the flag after writing 1 to it.)
1	Transition to S/W reset mode or transition to halt mode or transition to sleep mode (Initial value) [Setting condition] When reset/halt/sleep transition is completed after a reset (MCR0 or HW) or Halt mode (MCR1) or Sleep mode (MCR5) is requested

### 13.4.5 Interrupt Mask Register (IMR)

The interrupt mask register (IMR) is a 16 bit register that protects all corresponding interrupts in the Interrupt Request Register (IRR) from generating an output signal on the IRQ. An interrupt request is masked if the corresponding bit position is set to '1'. This register can be read or written at any time. The IMR directly controls the generation of IRQ, but does not prevent the setting of the corresponding bit in the IRR.

- IMR (Address = H'00A)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IMR15	IMR14	IMR13	IMR12	IMR11	IMR10	IMR9	IMR8	IMR7	IMR6	IMR5	IMR4	IMR3	IMR2	IMR1	IMR0
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

**Bit 15 to 0:** Maskable interrupt sources corresponding to IRR[15:0] respectively. When a bit is set, the interrupt signal is not generated, although setting the corresponding IRR bit is still performed.

Bit[15:0]: IMRn	Description
0	Corresponding IRR is not masked (IRQ is generated for interrupt conditions)
1	Corresponding interrupt of IRR is masked (Initial value)

### 13.4.6 Transmit Error Counter (TEC) and Receive Error Counter (REC)

The Transmit Error Counter (TEC) and Receive Error Counter (REC) is a 16-bit read/(write) register that functions as a counter indicating the number of transmit/receive message errors on the CAN Interface. The count value is stipulated in the CAN protocol specification Refs. [1], [2], [3] and [4]. In modes other than Write Error Counter test mode, this register is read only, and can only be modified by the CAN Interface. This register can be cleared by a Reset request (MCR0) or entering to bus off.

In Write Error Counter test mode (i.e. TST[2:0] = 3'b100), it is possible to write to this register. The same value can only be written to TEC/REC, and the value written into TEC is set to TEC and REC. When writing to this register, RCAN-ET needs to be put into Halt Mode. This feature is only intended for test purposes.

- TEC/REC (Address = H'00C)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TEC7	TEC6	TEC5	TEC4	TEC3	TEC2	TEC1	TEC0	REC7	REC6	REC5	REC4	REC3	REC2	REC1	REC0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Note: \* It is only possible to write the value in test mode when TST[2:0] in MCR is 3'b100.

REC is incremented during Bus Off to count the recurrences of 11 recessive bits as requested by the Bus Off recovery sequence.

## 13.5 RCAN-ET Mailbox Registers

The following sections describe RCAN-ET Mailbox registers that control / flag individual Mailboxes. The address is mapped as follows.

**Important:** LongWord access is carried out as two consecutive Word accesses.

**Table 13.6 RCAN-ET Mailbox Registers**

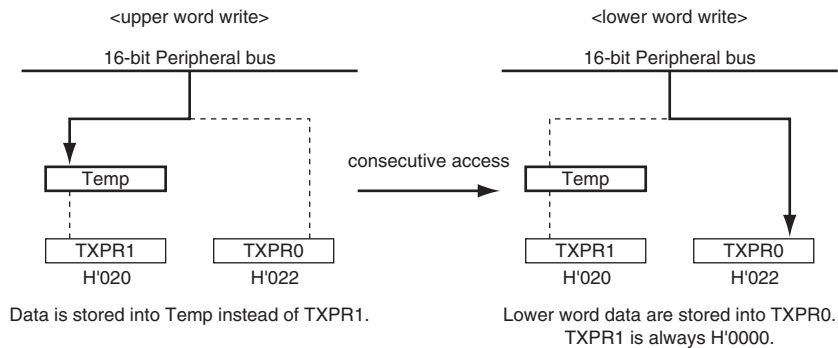

Description	Address	Name	Access Size (bits)
Transmit Pending 1	H'020	TXPR1	LW
Transmit Pending 0	H'022	TXPR0	—
	H'024		
	H'026		
	H'028		
Transmit Cancel 0	H'02A	TXCR0	
	H'02C		
	H'02E		
	H'030		
Transmit Acknowledge 0	H'032	TXACK0	Word
	H'034		
	H'036		
	H'038		
Abort Acknowledge 0	H'03A	ABACK0	Word
	H'03C		
	H'03E		
	H'040		
Data Frame Receive Pending 0	H'042	RXPR0	Word
	H'044		
	H'046		
	H'048		
Remote Frame Receive Pending 0	H'04A	RFPR0	Word
	H'04C		
	H'04E		
	H'050		

Description	Address	Name	Access Size (bits)
Mailbox Interrupt Mask Register 0	H'052	MBIMR0	Word
	H'054		
	H'056		
	H'058		
Unread Message Status Register 0	H'05A	UMSR0	Word
	H'05C		
	H'05E		

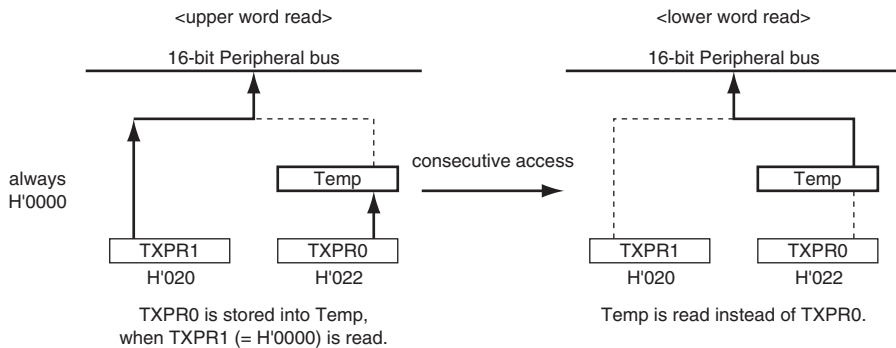

### 13.5.1 Transmit Pending Register (TXPR0, TXPR1)

The concatenation of TXPR0 and TXPR1 is a 32-bit register that contains any transmit pending flags for the CAN module. In the case of 16-bit bus interface, Long Word access is carried out as two consecutive word accesses.

<Longword Write Operation>

## &lt;Longword Read Operation&gt;

The TXPR1 register cannot be modified and it is always fixed to '0'. The TXPR0 controls Mailbox-15 to Mailbox-1. The CPU may set the TXPR bits to affect any message being considered for transmission by writing a '1' to the corresponding bit location. Writing a '0' has no effect, and TXPR cannot be cleared by writing a '0' and must be cleared by setting the corresponding TXCR bits. TXPR may be read by the CPU to determine which, if any, transmissions are pending or in progress. In effect there is a transmit pending bit for all Mailboxes except for the Mailbox-0. Writing a '1' to a bit location when the mailbox is not configured to transmit is not allowed.

The RCAN-ET will clear a transmit pending flag after successful transmission of its corresponding message or when a transmission abort is requested successfully from the TXCR. The TXPR flag is not cleared if the message is not transmitted due to the CAN node losing the arbitration process or due to errors on the CAN bus, and RCAN-ET automatically tries to transmit it again unless its DART bit (Disable Automatic Re-Transmission) is set in the Message-Control of the corresponding Mailbox. In such case (DART set), the transmission is cleared and notified through Mailbox Empty Interrupt Flag (IRR8) and the correspondent bit within the Abort Acknowledgement Register (ABACK).

If the status of the TXPR changes, the RCAN-ET shall ensure that in the identifier priority scheme (MCR2=0), the highest priority message is always presented for transmission in an intelligent way even under circumstances such as bus arbitration losses or errors on the CAN bus. Please refer to section 13.6, Application Note, for details.

When the RCAN-ET changes the state of any TXPR bit position to a '0', an empty slot interrupt (IRR8) may be generated. This indicates that either a successful or an aborted mailbox transmission has just been made. If a message transmission is successful it is signalled in the TXACK register, and if a message transmission abortion is successful it is signalled in the ABACK register. By checking these registers, the contents of the Message of the corresponding Mailbox may be modified to prepare for the next transmission.

- TXPR1

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXPR1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Note: \* Read value is always H'0000. Long word access is mandatory when reading or writing TXPR1/TXPR0. Write operation to TXPR1 has no effect.

- TXPR0

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXPR0[15:1]															0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	—

Note: \* It is possible only to write a '1' for a Mailbox configured as transmitter. Read value is always H'0000. Long word access is mandatory when reading or writing TXPR1/TXPR0. Write operation to bit 0 of TXPR0 has no effect.

**Bit 15 to 1** — indicates that the corresponding Mailbox is requested to transmit a CAN Frame. The bit 15 to 1 corresponds to Mailbox-15 to 1 respectively. When multiple bits are set, the order of the transmissions is governed by the MCR2 – CAN-ID or Mailbox number.

Bit[15:1]:TXPR0	Description
0	Transmit message idle state in corresponding mailbox (Initial value) [Clearing Condition] Completion of message transmission or message transmission abortion (automatically cleared)
1	Transmission request made for corresponding mailbox

**Bit 0— Reserved:** This bit is always '0' as this is a receive-only Mailbox. Writing a '1' to this bit position has no effect. The returned value is '0'.

### 13.5.2 Transmit Cancel Register (TXCR0)

The TXCR0 is a 16-bit read/conditionally-write register. The TXCR0 controls Mailbox-15 to Mailbox-1. This register is used by the CPU to request the pending transmission requests in the TXPR to be cancelled. To clear the corresponding bit in the TXPR the CPU must write a '1' to the bit position in the TXCR. Writing a '0' has no effect.

When an abort has succeeded the CAN controller clears the corresponding TXPR + TXCR bits, and sets the corresponding ABACK bit. However, once a Mailbox has started a transmission, it cannot be cancelled by this bit. In such a case, if the transmission finishes in success, the CAN controller clears the corresponding TXPR + TXCR bit, and sets the corresponding TXACK bit, however, if the transmission fails due to a bus arbitration loss or an error on the bus, the CAN controller clears the corresponding TXPR + TXCR bit, and sets the corresponding ABACK bit. If an attempt is made by the CPU to clear a mailbox transmission that is not transmit-pending it has no effect. In this case the CPU will be not able at all to set the TXCR flag.

- TXCR0

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXCR0[15:1]															0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	—

Note: \* Only writing a '1' to a Mailbox that is requested for transmission and is configured as transmit.

**Bit 15 to 1** — requests the corresponding Mailbox, that is in the queue for transmission, to cancel its transmission. The bit 15 to 1 corresponds to Mailbox-15 to 1 (and TXPR0[15:1]) respectively.

Bit[15:1]:TXCR0	Description
0	Transmit message cancellation idle state in corresponding mailbox (Initial value) [Clearing Condition] Completion of transmit message cancellation (automatically cleared)
1	Transmission cancellation request made for corresponding mailbox

**Bit 0** — This bit is always '0' as this is a receive-only mailbox. Writing a '1' to this bit position has no effect and always read back as a '0'.

### 13.5.3 Transmit Acknowledge Register0 (TXACK0)

The TXACK0 is a 16-bit read/conditionally-write register. This register is used to signal to the CPU that a mailbox transmission has been successfully made. When a transmission has succeeded the RCAN-ET sets the corresponding bit in the TXACK register. The CPU may clear a TXACK bit by writing a '1' to the corresponding bit location. Writing a '0' has no effect.

- TXACK0

Note: \* Only when writing a '1' to clear.

**Bit 15 to 1** — notifies that the requested transmission of the corresponding Mailbox has been finished successfully. The bit 15 to 1 corresponds to Mailbox-15 to 1 respectively.

Bit[15:1]:TXACK0	Description
0	[Clearing Condition] Writing '1' (Initial value)
1	Corresponding Mailbox has successfully transmitted message (Data or Remote Frame)  [Setting Condition] Completion of message transmission for corresponding mailbox

**Bit 0** — This bit is always '0' as this is a receive-only mailbox. Writing a '1' to this bit position has no effect and always read back as a '0'.

### 13.5.4 Abort Acknowledge Register0 (ABACK0)

The ABACK0 is a 16-bit read/conditionally-write register. This register is used to signal to the CPU that a mailbox transmission has been aborted as per its request. When an abort has succeeded the RCAN-ET sets the corresponding bit in the ABACK register. The CPU may clear the Abort Acknowledge bit by writing a '1' to the corresponding bit location. Writing a '0' has no effect. An ABACK bit position is set by the RCAN-ET to acknowledge that a TXPR bit has been cleared by the corresponding TXCR bit.

- ABACK0

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ABACK0[15:1]															0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	—

Note: \* Only when writing a '1' to clear.

**Bit 15 to 1** — notifies that the requested transmission cancellation of the corresponding Mailbox has been performed successfully. The bit 15 to 1 corresponds to Mailbox-15 to 1 respectively.

Bit[15:1]:ABACK0	Description
0	[Clearing Condition] Writing '1' (Initial value)
1	Corresponding Mailbox has cancelled transmission of message (Data or Remote Frame) [Setting Condition] Completion of transmission cancellation for corresponding mailbox

**Bit 0** — This bit is always '0' as this is a receive-only mailbox. Writing a '1' to this bit position has no effect and always read back as a '0'.

### 13.5.5 Data Frame Receive Pending Register0 (RXPR0)

The RXPR0 is a 16-bit read/conditionally-write register. The RXPR is a register that contains the received Data Frames pending flags associated with the configured Receive Mailboxes. When a CAN Data Frame is successfully stored in a receive mailbox the corresponding bit is set in the RXPR. The bit may be cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. However, the bit may only be set if the mailbox is configured by its MBC (Mailbox Configuration) to receive Data Frames. When a RXPR bit is set, it also sets IRR1 (Data Frame Received Interrupt Flag) if its MBIMR (Mailbox Interrupt Mask Register) is not set, and the interrupt signal is generated if IMR1 is not set. Please note that these bits are only set by receiving Data Frames and not by receiving Remote frames.

- RXPR0

Note: \* Only when writing a '1' to clear.

**Bit 15 to 0** — Configurable receive mailbox locations corresponding to each mailbox position from 15 to 0 respectively.

Bit[15:0]: RXPR0	Description
0	[Clearing Condition] Writing '1' (Initial value)
1	Corresponding Mailbox received a CAN Data Frame [Setting Condition] Completion of Data Frame receive on corresponding mailbox

### 13.5.6 Remote Frame Receive Pending Register0 (RFPR0)

The RFPR0 is a 16-bit read/conditionally-write register. The RFPR is a register that contains the received Remote Frame pending flags associated with the configured Receive Mailboxes. When a CAN Remote Frame is successfully stored in a receive mailbox the corresponding bit is set in the RFPR. The bit may be cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. In effect there is a bit position for all mailboxes. However, the bit may only be set if the mailbox is configured by its MBC (Mailbox Configuration) to receive Remote Frames. When a RFPR bit is set, it also sets IRR2 (Remote Frame Request Interrupt Flag) if its MBIMR (Mailbox Interrupt Mask Register) is not set, and the interrupt signal is generated if IMR2 is not set. Please note that these bits are only set by receiving Remote Frames and not by receiving Data frames.

- RFPR0

Note: \* Only when writing a '1' to clear.

**Bit 15 to 0** — Remote Request pending flags for mailboxes 15 to 0 respectively.

Bit[15:0]: RFPR0	Description
0	[Clearing Condition] Writing '1' (Initial value)
1	Corresponding Mailbox received Remote Frame [Setting Condition] Completion of remote frame receive in corresponding mailbox

### 13.5.7 Mailbox Interrupt Mask Register0 (MBIMR0)

The MBIMR0 is a 16-bit read/write register. The MBIMR only prevents the setting of IRR related to the Mailbox activities, that are IRR[1] – Data Frame Received Interrupt, IRR[2] – Remote Frame Request Interrupt, IRR[8] – Mailbox Empty Interrupt, and IRR[9] – Message OverRun/OverWrite Interrupt. If a mailbox is configured as receive, a mask at the corresponding bit position prevents the generation of a receive interrupt (IRR[1] and IRR[2] and IRR[9]) but does not prevent the setting of the corresponding bit in the RXPR or RFPR or UMSR. Similarly when a mailbox has been configured for transmission, a mask prevents the generation of an Interrupt signal and setting of an Mailbox Empty Interrupt due to successful transmission or abortion of transmission (IRR[8]), however, it does not prevent the RCAN-ET from clearing the corresponding TXPR/TXCR bit + setting the TXACK bit for successful transmission, and it does not prevent the RCAN-ET from clearing the corresponding TXPR/TXCR bit + setting the ABACK bit for abortion of the transmission.

A mask is set by writing a '1' to the corresponding bit position for the mailbox activity to be masked. At reset all mailbox interrupts are masked.

- MBIMR0

**Bit 15 to 0** — Enable or disable interrupt requests from individual Mailbox-15 to Mailbox-0 respectively.

Bit[15:0]: MBIMR0	Description
0	Interrupt Request from IRR1/IRR2/IRR8/IRR9 enabled
1	Interrupt Request from IRR1/IRR2/IRR8/IRR9 disabled (initial value)

### 13.5.8 Unread Message Status Register0 (UMSR0)

The UMSR0 is a 16-bit read/conditionally write register and it records the mailboxes whose contents have not been accessed by the CPU prior to a new message being received. If the CPU has not cleared the corresponding bit in the RXPR or RFPR when a new message for that mailbox is received, the corresponding UMSR bit is set to '1'. This bit may be cleared by writing a '1' to the corresponding bit location in the UMSR. Writing a '0' has no effect.

If a mailbox is configured as transmit box, the corresponding UMSR will not be set.

- UMSR0

**Bit 15 to 0** — Indicate that an unread received message has been overwritten or overrun condition has occurred for Mailboxes 15 to 0.

<b>Bit[15:0]: UMSR0</b>	<b>Description</b>
0	[Clearing Condition] Writing '1' (initial value)
1	Unread received message is overwritten by a new message or overrun condition  [Setting Condition] When a new message is received before RXPR or RFPR is cleared

### 13.5.9 RCAN Monitor Register (RCANMON)

RCANMON controls the transmission stop for CTx pin, enables/disables RCAN-ET transmission/reception pins, and monitors the status of RCAN-ET pins. This register is not initialized by the software reset (MCR0).

Bit	7	6	5	4	3	2	1	0
Bit Name	—	CTxSTP	RCANE	—	—	—	CTxD	CRxD
Initial Value	0	0	0	Undefined	Undefined	Undefined	Undefined	Undefined
R/W	—	R/W	R/W	—	—	—	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	—	Undefined	R/W	Reserved Reading/writing to this bit is invalid.
6	CTxSTP	0	R/W	CTx Transmit Stop Setting this bit to 1 forces CTx pin to be set to 1, whether or not the RCAN-ET is transmitting data.
5	RCANE	0	R/W	RCAN-ET Transmit/Receive Pin Enable Setting this bit to 1 enables CTx and CRx pins of the RCAN-ET are enabled.
4 to 2	—	All undefined	—	Reserved Reading/writing to these bits is invalid.
1	CTxD	Undefined	R	CTx Transmit Data Monitor The status of CTx pin is acquired when this bit is read. Writing to this bit is invalid.
0	CRxD	Undefined	R	CRx Receive Data Monitor The status of CRx pin is acquired when this bit is read. Writing to this bit is invalid.

Figure 13.6 shows a diagram to illustrate how those bits of RCANMON are connected together to form a port interface.

**Figure 13.6 Connection Diagram of Port Interface**

## 13.6 Application Note

### 13.6.1 Configuration of RCAN-ET

RCAN-ET is considered in configuration mode or after a H/W (Power On Reset)/ S/W (MCR[0]) reset or when in Halt mode. In both conditions RCAN-ET cannot join the CAN Bus activity and configuration changes have no impact on the traffic on the CAN Bus.

#### (1) After a reset request

The following sequence is an example of how to configure the RCAN-ET after (S/W or H/W) reset. After reset, all the registers are initialised, therefore, RCAN-ET needs to be configured before joining the CAN bus activity. Please read the notes carefully.

**Figure 13.7 Reset Sequence**

## (2) Halt mode

When RCAN-ET is in Halt mode, it cannot take part to the CAN bus activity. Consequently the user can modify all the requested registers without influencing existing traffic on the CAN Bus. It is important for this that the user waits for the RCAN-ET to be in halt mode before to modify the requested registers - note that the transition to Halt Mode is not always immediate (transition will occur when the CAN Bus is idle or in intermission). After RCAN-ET transit to Halt Mode, GSR4 is set.

Once the configuration is completed the Halt request needs to be released. RCAN-ET will join CAN Bus activity after the detection of 11 recessive bits on the CAN Bus.

## (3) Sleep mode

When RCAN-ET is in sleep mode the clock for the main blocks of the IP is stopped in order to reduce power consumption. Only the following user registers are clocked and can be accessed: MCR, GSR, IRR and IMR. Interrupt related to transmission (TXACK and ABACK) and reception (RXPR and RFPR) cannot be cleared when in sleep mode (as TXACK, ABACK, RXPR and RFPR are not accessible) and must to be cleared beforehand.

The following diagram shows the flow to follow to move RCAN-ET into sleep mode.

### (4) Can sleep mode

Figure 13.8 Halt Mode/Sleep Mode

Figure 13.9 - Halt Mode/Sleep Mode shows allowed state transition.

- Please don't set MCR5 (Sleep Mode) without entering Halt Mode.
- After MCR1 is set, please don't clear it before GSR4 is set and RCAN-ET enters Halt Mode.

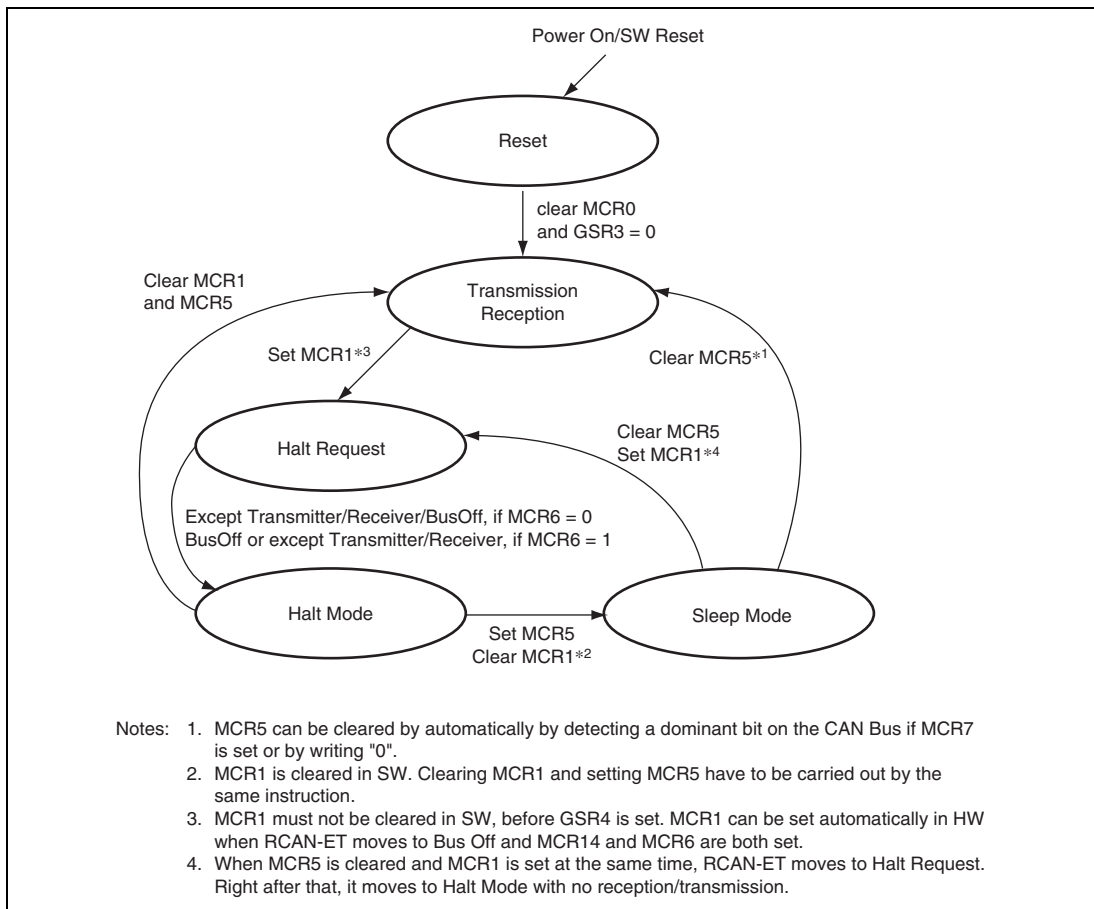

Figure 13.9 Halt Mode/Sleep Mode

The following table shows conditions to access registers.

**Table 13.7 Conditions to access registers**

Status Mode	RCAN-ET Registers								
	MCR GSR	IRR IMR	BCR	MBIMR	Flag_register	mailbox (ctr10, LAFM)	mailbox (data)	mailbox (ctr11)	
Reset	yes	yes	yes	yes	yes	yes	yes	yes	
Transmission Reception Halt Request	yes	yes	no* <sup>1</sup>	yes	yes	no* <sup>1</sup>	yes* <sup>2</sup>	yes* <sup>2</sup>	no* <sup>1</sup> yes* <sup>2</sup>
Halt	yes	yes	no* <sup>1</sup>	yes	yes	yes	yes	yes	
Sleep	yes	yes	no	no	no	no	no	no	

Notes: 1. No hardware protection  
2. When TXPR is not set.

### 13.6.2 Test Mode Settings

The RCAN-ET has various test modes. The register TST[2:0] (MCR[10:8]) is used to select the RCAN-ET test mode. The default (initialised) settings allow RCAN-ET to operate in Normal mode. The following table is examples for test modes.

Test Mode can be selected only while in configuration mode. The user must then exit the configuration mode (ensuring BCR0/BCR1 is set) in order to run the selected test mode.

**Table.13.8 Test Mode Settings**

Bit10: TST2	Bit9: TST1	Bit8: TST0	Description
0	0	0	Normal Mode (initial value)
0	0	1	Listen-Only Mode (Receive-Only Mode)
0	1	0	Self Test Mode 1 (External)
0	1	1	Self Test Mode 2 (Internal)
1	0	0	Write Error Counter
1	0	1	Error Passive Mode
1	1	0	Setting prohibited
1	1	1	Setting prohibited

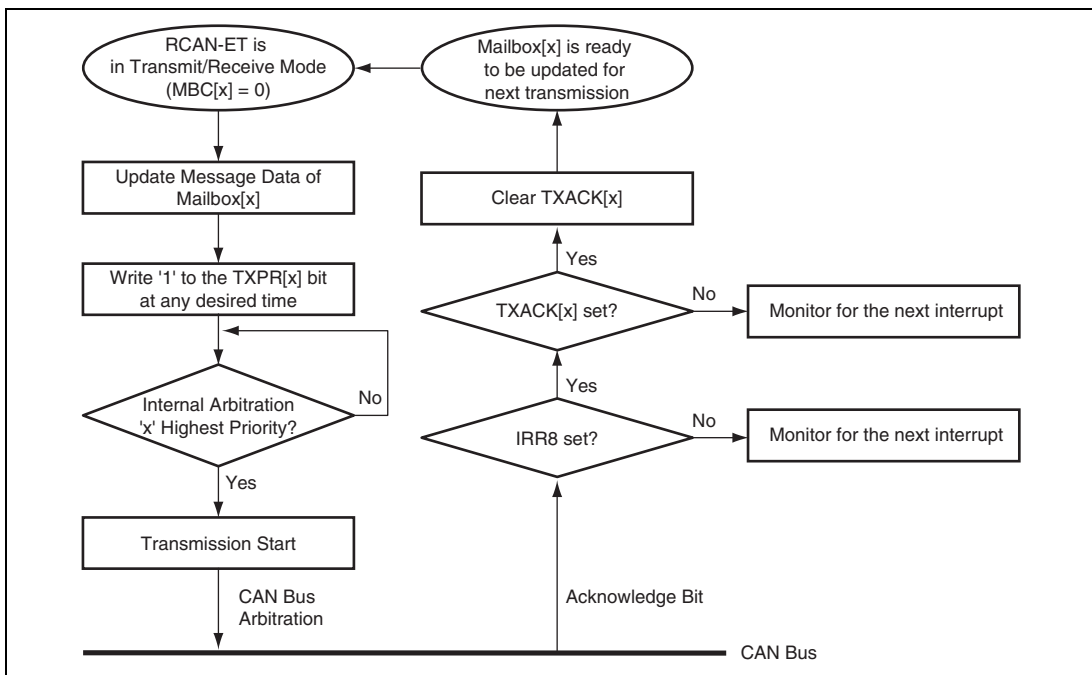

- Normal Mode  
RCAN-ET operates in the normal mode.
  - Listen-Only Mode:  
ISO-11898 requires this mode for baud rate detection. The Error Counters are cleared and disabled so that the TEC/REC does not increase the values, and the CTx Output is disabled so that RCAN-ET does not generate error frames or acknowledgment bits. IRR13 is set when a message error occurs.
  - Self Test Mode 1  
RCAN-ET generates its own Acknowledge bit, and can store its own messages into a reception mailbox (if required). The CRx/CTx pins must be connected to the CAN bus.
  - Self Test Mode 2  
RCAN-ET generates its own Acknowledge bit, and can store its own messages into a reception mailbox (if required). The CRx/CTx pins do not need to be connected to the CAN bus or any external devices, as the internal CTx is looped back to the internal CRx. CTx pin outputs only recessive bits and CRx pin is disabled.
  - Write Error Counter  
TEC/REC can be written in this mode. RCAN-ET can be forced to become an Error Passive mode by writing a value greater than 127 into the Error Counters. The value written into TEC is used to write into REC, so only the same value can be set to these registers. Similarly, RCAN-ET can be forced to become an Error Warning by writing a value greater than 95 into them.
  - Error Passive mode  
RCAN-ET needs to be in Halt Mode when writing into TEC/REC (MCR1 must be "1" when writing to the Error Counter). Furthermore this test mode needs to be exited prior to leaving Halt mode. Error Passive Mode: RCAN-ET can be forced to enter Error Passive mode.
- Note: the REC will not be modified by implementing this Mode. However, once running in Error Passive Mode, the REC will increase normally should errors be received. In this Mode, RCAN-ET will enter Bus Off if TEC reaches 256 (Dec). However when this mode is used RCAN-ET will not be able to become Error Active. Consequently, at the end of the Bus Off recovery sequence, RCAN-ET will move to Error Passive and not to Error Active

When message error occurs, IRR13 is set in all test modes.

### 13.6.3 Message Transmission Sequence

#### (1) Message Transmission Request

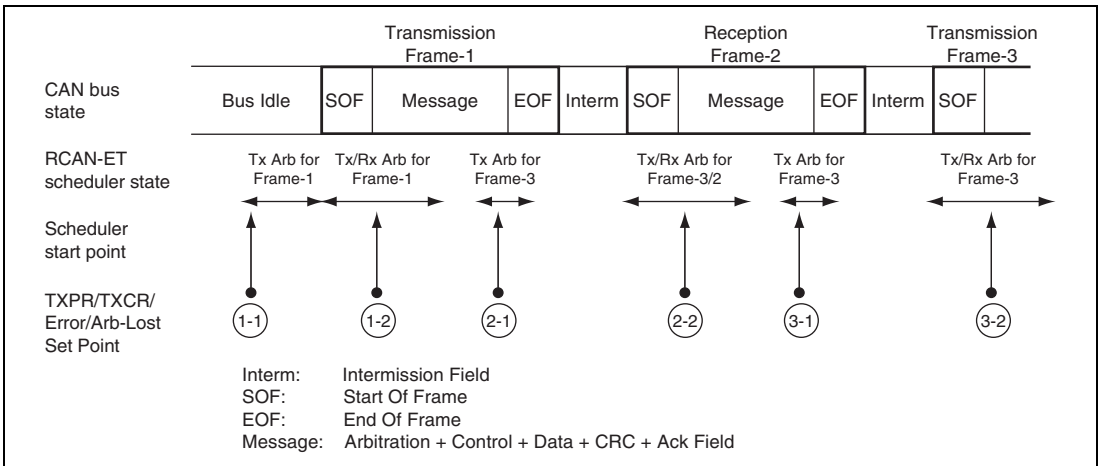

The sequence to transmit a CAN frame onto the bus is shown in figure 13.10. As described in the previous register section, please note that IRR8 is set when one of the TXACK or ABACK bits is set, meaning one of the Mailboxes has completed its transmission or transmission abortion and is now ready to be updated for the next transmission, whereas, the GSR2 means that there is currently no transmission request made (No TXPR flags set).

**Figure 13.10** Transmission Request

#### (2) Internal Arbitration for Transmission

The following diagram explains how RCAN-ET manages to schedule transmission-requested messages in the correct order based on the CAN identifier. 'Internal arbitration' picks up the highest priority message amongst transmit-requested messages.

**Figure 13.11 Internal Arbitration for transmission**

The RCAN-ET has two state machines. One is for transmission, and the other is for reception.

- 1-1: When a TXPR bit(s) is set while the CAN bus is idle, the internal arbitration starts running immediately and the transmission is started.
- 1-2: Operations for both transmission and reception starts at SOF. Since there is no reception frame, RCAN-ET becomes transmitter.
- 2-1: At crc delimiter, internal arbitration to search next message transmitted starts.
- 2-2: Operations for both transmission and reception starts at SOF. Because of a reception frame with higher priority, RCAN-ET becomes receiver. Therefore, Reception is carried out instead of transmitting Frame-3.
- 3-1: At crc delimiter, internal arbitration to search next message transmitted starts.
- 3-2: Operations for both transmission and reception starts at SOF. Since a transmission frame has higher priority than reception one, RCAN-ET becomes transmitter.

Internal arbitration for the next transmission is also performed at the beginning of each error delimiter in case of an error is detected on the CAN Bus. It is also performed at the beginning of error delimiters following overload frame.

As the arbitration for transmission is performed at CRC delimiter, in case a remote frame request is received into a Mailbox with ATX=1 the answer can join the arbitration for transmission only at the following Bus Idle, CRC delimiter or Error Delimiter.

Depending on the status of the CAN bus, following the assertion of the TXCR, the corresponding Message abortion can be handled with a delay of maximum 1 CAN Frame.

### 13.6.4 Message Receive Sequence

The diagram below shows the message receive sequence.

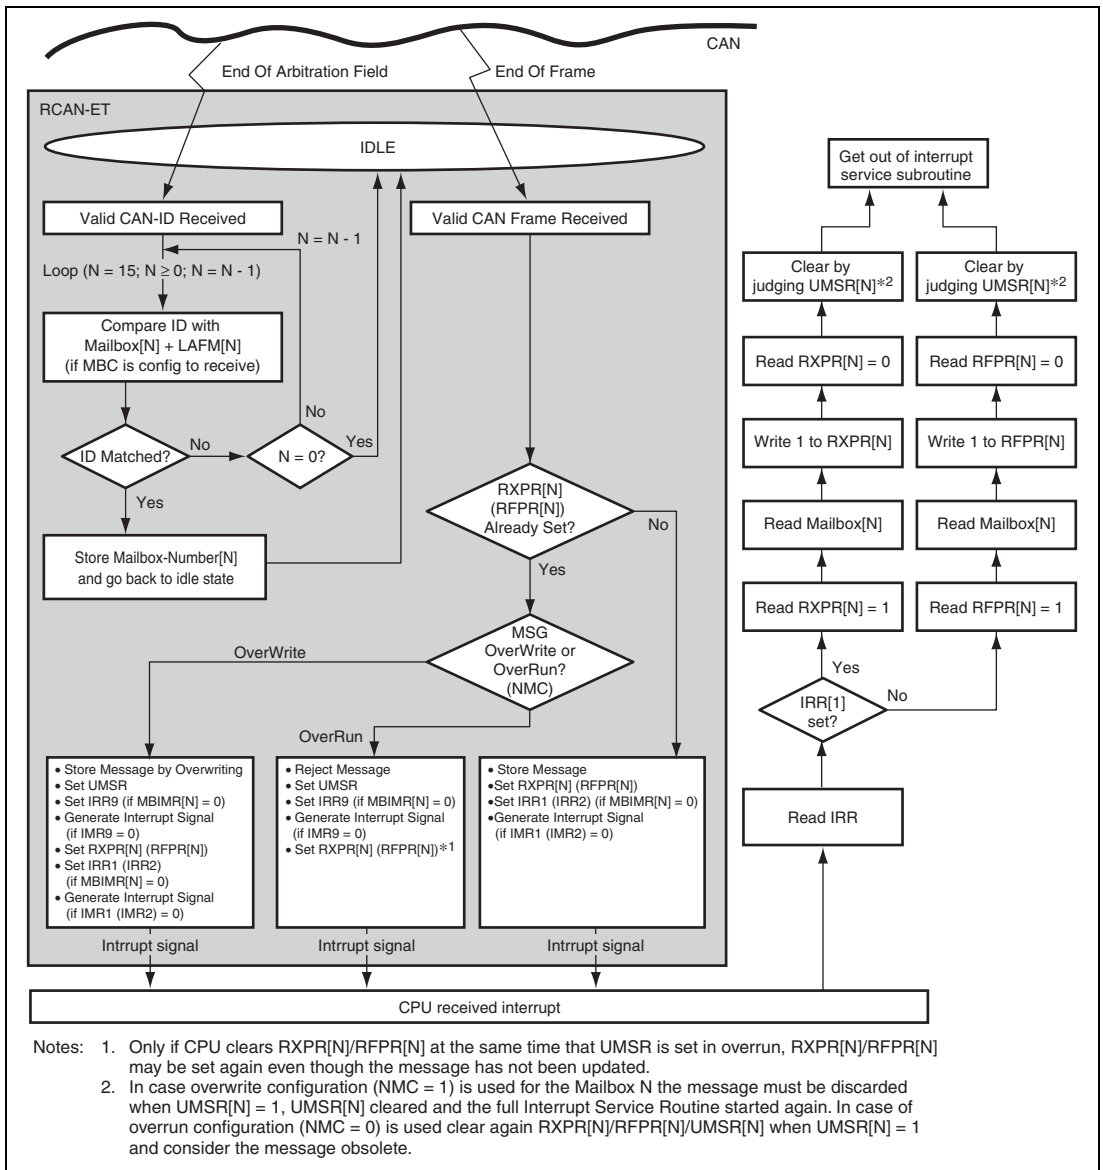

Figure 13.12 Message receive sequence

When RCAN-ET recognises the end of the Arbitration field while receiving a message, it starts comparing the received identifier to the identifiers set in the Mailboxes, starting from Mailbox-15 down to Mailbox-0. It first checks the MBC if it is configured as a receive box, and reads LAFM, and reads the CAN-ID of Mailbox-15 (if configured as receive) to finally compare them to the received ID. If it does not match, the same check takes place at Mailbox-14 (if configured as receive). Once RCAN-ET finds a matching identifier, it stores the number of Mailbox-[N] into an internal buffer, stops the search, and goes back to idle state, waiting for the EndOfFrame (EOF) to come. When the 6<sup>th</sup> bit of EOF is notified by the CAN Interface logic, the received message is written or abandoned, depending on the NMC bit. No modification of configuration during communication is allowed. Entering Halt Mode is one of ways to modify configuration. If it is written into the corresponding Mailbox, including the CAN-ID, i.e., there is a possibility that the CAN-ID is overwritten by a different CAN-ID of the received message due to the LAFM used. This also implies that, if the identifier of a received message matches to ID + LAFM of 2 or more Mailboxes, the higher numbered Mailbox will always store the relevant messages and the lower numbered Mailbox will never receive messages. Therefore, the settings of the identifiers and LAFMs need to be carefully selected.

With regards to the reception of data and remote frames described in the above flow diagram the clearing of the UMSR flag after the reading of IRR is to detect situations where a message is overwritten by a new incoming message stored in the same mailbox while the interrupt service routine is running. If during the final check of UMSR a overwrite condition is detected the message needs to be discarded and read again.

In case UMSR is set and the Mailbox is configured for overrun (NMC = 0), the message is still valid, however it is obsolete as it is not reflecting the latest message monitored on the CAN bus.

Please access the full Mailbox content (area of Mailbox[N]) before clearing the related RXPR/RFPR flag.

Please note that in the case a received remote frame is overwritten by a data frame, both the remote frame request interrupt (IRR2) and data frame received interrupt (IRR1) and also the Receive Flags (RXPR and RFPR) are set. In an analogous way, the overwriting of a data frame by a remote frame, leads to setting both IRR2 and IRR1.

In the Overrun Mode (NMC = '0'), only the first Mailbox will cause the flags to be asserted. So, if a Data Frame is initially received, then RXPR and IPR1 are both asserted. If a Remote Frame is then received before the Data Frame has been read, then RFPR and IRR2 are NOT set. In this case UMSR of the corresponding Mailbox will still be set.

### 13.6.5 Reconfiguration of Mailbox

When re-configuration of Mailboxes is required, the following procedures should be taken.

#### (1) Change configuration of transmit box

Two cases are possible.

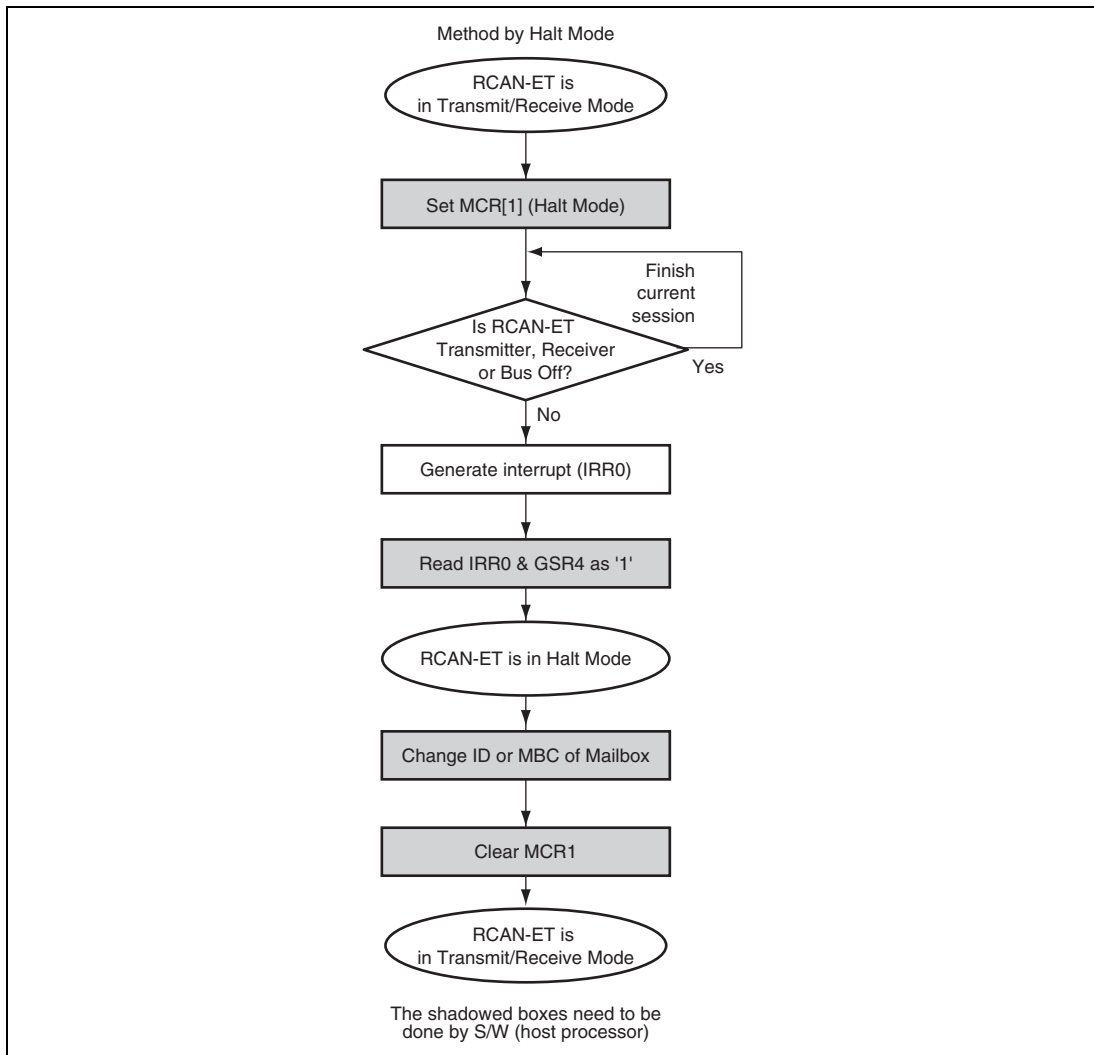

- Change of ID, RTR, IDE, LAFM, Data, DLC, NMC, ATX, DART  
This change is possible only when MBC=3'b000. Confirm that the corresponding TXPR is not set. The configuration (except MBC bit) can be changed at any time.
- Change from transmit to receive configuration (MBC)  
Confirm that the corresponding TXPR is not set. The configuration can be changed only in Halt or reset state. Please note that it might take longer for RCAN-ET to transit to halt state if it is receiving or transmitting a message (as the transition to the halt state is delayed until the end of the reception/transmission), and also RCAN-ET will not be able to receive/transmit messages during the Halt state.  
In case RCAN-ET is in the Bus Off state the transition to halt state depends on the configuration of the bit 6 of MCR and also bit and 14 of MCR.

#### (2) Change configuration (ID, RTR, IDE, LAFM, Data, DLC, NMC, ATX, DART, MBC) of receive box or Change receive box to transmit box

The configuration can be changed only in Halt Mode.

RCAN-ET will not lose a message if the message is currently on the CAN bus and RCAN-ET is a receiver. RCAN-ET will be moving into Halt Mode after completing the current reception. Please note that it might take longer if RCAN-ET is receiving or transmitting a message (as the transition to the halt state is delayed until the end of the reception/transmission), and also RCAN-ET will not be able to receive/transmit messages during the Halt Mode.

In case RCAN-ET is in the Bus Off state the transition to halt mode depends on the configuration of the bit 6 and 14 of MCR.

**Figure 13.13 Change ID of Receive Box or Change Receive Box to Transmit Box**

## 13.7 Interrupt Sources

Table 13.9 lists the RCAN-ET interrupt sources. With the exception of the reset processing interrupt (IRR0) by a power-on reset, these sources can be masked. Masking is implemented using the mailbox interrupt mask register 0 (MBIMR0) and interrupt mask register (IMR). For details on the interrupt vector of each interrupt source, see section 5, Interrupt Controller.

**Table 13.9 RCAN-ET Interrupt Sources**

Channel	Interrupt	Description	Interrupt Flag	DMAC Activation
0	ERS_0	Error Passive Mode ( $TEC \geq 128$ or $REC \geq 128$ )	IRR5	Not possible
		Bus Off ( $TEC \geq 256$ )/Bus Off recovery	IRR6	
		Error warning ( $TEC \geq 96$ )	IRR3	
		Error warning ( $REC \geq 96$ )	IRR4	
	OVR_0	Message error detection	IRR13* <sup>1</sup>	
		Reset/halt/CAN sleep transition	IRR0	
		Overload frame transmission	IRR7	
		Unread message overwrite (overrun)	IRR9	
		Detection of CAN bus operation in CAN sleep mode	IRR12	
	SLE_0	Message transmission/transmission disabled (slot empty)	IRR8	
RM1_0* <sup>2</sup>	Data frame reception/	IRR1* <sup>3</sup>		
RM0_0* <sup>2</sup>	Remote frame reception	IRR2* <sup>3</sup>	Possible* <sup>4</sup>	

- Notes:
1. Available only in Test Mode.
  2. RM0 is an interrupt generated by the remote request pending flag for mailbox 0 (RFPR0[0]) or the data frame receive flag for mailbox 0 (RXPR0[0]). RM1 is an interrupt generated by the remote request pending flag for mailbox n (RFPR0[n]) or the data frame receive flag for mailbox n (RXPR0[n]) (n = 1 to 15).
  3. IRR1 is a data frame received interrupt flag for mailboxes 0 to 15, and IRR2 is a remote frame request interrupt flag for mailboxes 0 to 15.
  4. Only a RM0\_0 interrupt enables the DMAC activation.

## 13.8 DMAC Interface

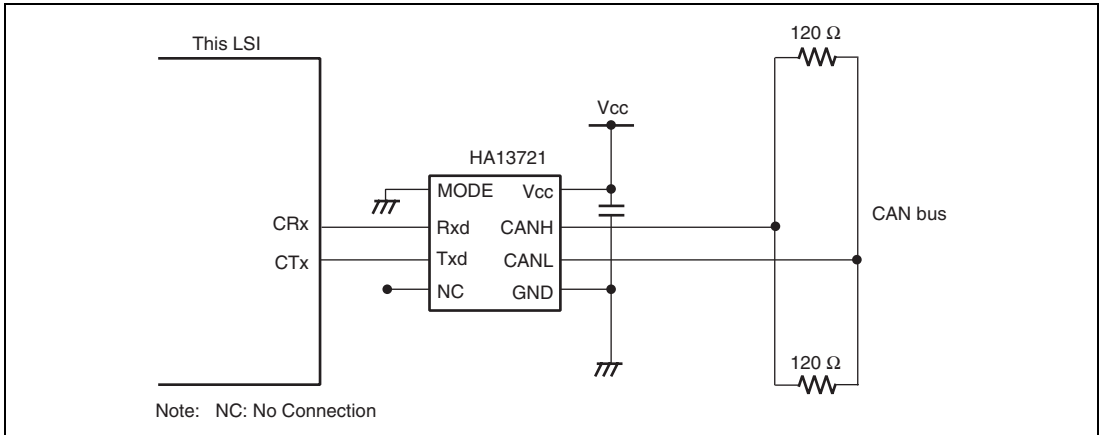

The DMAC can be activated by the reception of a message in RCAN-ET mailbox 0. When the DMAC activation is set and DMAC transfer ends, the flags in RXPR0 and RFPR0 are automatically cleared. At this point, an interrupt request is not sent to the CPU by a reception interrupt from the RCAN-ET. Figure 13.14 shows a DMAC transfer flowchart.

**Figure 13.14 DMAC Transfer Flowchart**

## 13.9 CAN Bus Interface

A bus transceiver IC is necessary to connect this LSI to a CAN bus. A Renesas HA13721 transceiver IC and its compatible products are recommended. Figure 13.15 shows a sample connection diagram.

**Figure 13.15 High-Speed Interface Using HA13721**

## 13.10 Usage Notes

### 13.10.1 Module Stop Mode

The module stop control register (MSTPCRC) controls the supply of clocks to RCAN-ET. As an initial value, the clock to RCAN-ET is halted. Registers except for the RCAN-ET monitor register (RCANMON) should be accessed after the module stop mode is released.

### 13.10.2 Reset

Two types of resets are supported for RCAN-ET.

- **Hardware reset**  
RCAN-ET is initialized by a power-on reset, or hardware standby, module stop, or software standby mode.
- **Software reset**  
The MCR0 bit in the master control register (MCR) initializes registers other than MCR and CAN communication functions. RCAN monitor register (RCANMON) is not initialized by this.

As the IRR0 bit in the interrupt request register (IRR) is initialized and set to 1 at a reset, it should be cleared to 0 in the configuration mode shown in the reset sequence diagram.

The area except for the message control field 1 (CONTROL1) of Mailbox is consisted of RAM, and not initialized at a reset. After a power-on reset, all the Mailboxes should be initialized in the configuration mode shown in the reset sequence diagram.

### 13.10.3 CAN Sleep Mode

The supply of main clocks in the modules is stopped in CAN sleep mode. Therefore, registers other than MCR, GSR, IRR, and IMR should not be accessed in CAN sleep mode.

### 13.10.4 Register Access

When the CAN bus receive frame is being stored in the Mailbox with the CAN communication functions of RCAN-ET, accessing the Mailbox area generates 0 to 5 peripheral bus cycles as a wait.

### 13.10.5 Interrupts

As shown in table 13.9, the Mailbox 0 receive interrupt enables the DMAC activation. When an interrupt is specified as to be activated by the Mailbox 0 receive interrupt and cleared by the interrupt source at the DMA transfer, up to the message control field 1 (CONTROL1) of Mailbox 0 should be read using the block transfer mode.

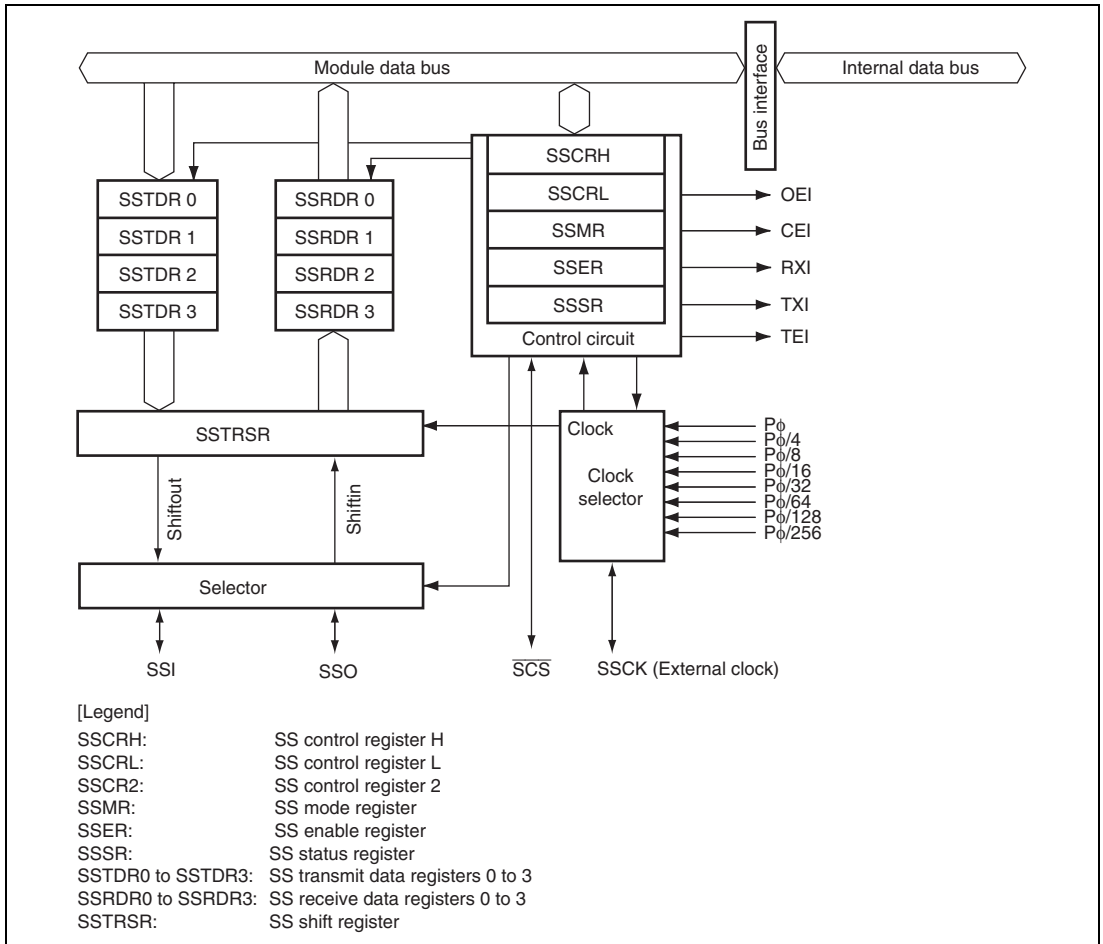

## Section 14 Synchronous Serial Communication Unit (SSU)

This LSI has three independent synchronous serial communication unit (SSU) channels. The SSU has master mode in which this LSI outputs clocks as a master device for synchronous serial communication and slave mode in which clocks are input from an external device for synchronous serial communication. Synchronous serial communication can be performed with devices having different clock polarity and clock phase. Figure 14.1 is a block diagram of the SSU.

### 14.1 Features

- Choice of SSU mode and clock synchronous mode
- Choice of master mode and slave mode
- Choice of standard mode and bidirectional mode
- Synchronous serial communication with devices with different clock polarity and clock phase
- Choice of 8/16/24/32-bit width of transmit/receive data
- Full-duplex communication capability  
The shift register is incorporated, enabling transmission and reception to be executed simultaneously.
- Consecutive serial communication
- Choice of LSB-first or MSB-first transfer
- Choice of a clock source  
Pφ/4, Pφ/8, Pφ/16, Pφ/32, Pφ/64, Pφ/128, Pφ/256, or an external clock
- Five interrupt sources  
Transmit-end, transmit-data-register-empty, receive-data-full, overrun-error, and conflict error
- Module stop mode can be set

Figure 14.1 shows a block diagram of the SSU.

**Figure 14.1 Block Diagram of SSU**

## 14.2 Input/Output Pins

Table 14.1 shows the SSU pin configuration.

**Table 14.1 Pin Configuration**

Channel	Abbr.*	I/O	Function
0	SSCK0	I/O	Channel 0 SSU clock input/output
	SSI0	I/O	Channel 0 SSU data input/output
	SSO0	I/O	Channel 0 SSU data input/output
	$\overline{SCS0}$	I/O	Channel 0 SSU chip select input/output
1	SSCK1	I/O	Channel 1 SSU clock input/output
	SSI1	I/O	Channel 1 SSU data input/output
	SSO1	I/O	Channel 1 SSU data input/output
	$\overline{SCS1}$	I/O	Channel 1 SSU chip select input/output
2	SSCK2	I/O	Channel 2 SSU clock input/output
	SSI2	I/O	Channel 2 SSU data input/output
	SSO2	I/O	Channel 2 SSU data input/output
	$\overline{SCS2}$	I/O	Channel 2 SSU chip select input/output

Note: \* Because channel numbers are omitted in later descriptions, these are shown SSCK, SSI, SSO, and  $\overline{SCS}$ .

## 14.3 Register Descriptions

The SSU has the following registers.

### (1) Channel 0

- SS control register H\_0 (SSCRH\_0)
- SS control register L\_0 (SSCRL\_0)
- SS mode register\_0 (SSMR\_0)
- SS enable register\_0 (SSER\_0)
- SS status register\_0 (SSSR\_0)
- SS control register 2\_0 (SSCR2\_0)
- SS transmit data register 0\_0 (SSTDR0\_0)
- SS transmit data register 1\_0 (SSTDR1\_0)
- SS transmit data register 2\_0 (SSTDR2\_0)
- SS transmit data register 3\_0 (SSTDR3\_0)
- SS receive data register 0\_0 (SSRDR0\_0)
- SS receive data register 1\_0 (SSRDR1\_0)
- SS receive data register 2\_0 (SSRDR2\_0)
- SS receive data register 3\_0 (SSRDR3\_0)
- SS shift register\_0 (SSTRSR\_0)

**(2) Channel 1**

- SS control register H\_1 (SSCRH\_1)
- SS control register L\_1 (SSCRL\_1)
- SS mode register\_1 (SSMR\_1)
- SS enable register\_1 (SSER\_1)
- SS status register\_1 (SSSR\_1)
- SS control register 2\_1 (SSCR2\_1)
- SS transmit data register 0\_1 (SSTDR0\_1)
- SS transmit data register 1\_1 (SSTDR1\_1)
- SS transmit data register 2\_1 (SSTDR2\_1)
- SS transmit data register 3\_1 (SSTDR3\_1)
- SS receive data register 0\_1 (SSRDR0\_1)
- SS receive data register 1\_1 (SSRDR1\_1)
- SS receive data register 2\_1 (SSRDR2\_1)
- SS receive data register 3\_1 (SSRDR3\_1)
- SS shift register\_1 (SSTRSR\_1)

**(3) Channel 2**

- SS control register H\_2 (SSCRH\_2)
- SS control register L\_2 (SSCRL\_2)
- SS mode register\_2 (SSMR\_2)
- SS enable register\_2 (SSER\_2)
- SS status register\_2 (SSSR\_2)
- SS control register 2\_2 (SSCR2\_2)
- SS transmit data register 0\_2 (SSTDR0\_2)
- SS transmit data register 1\_2 (SSTDR1\_2)
- SS transmit data register 2\_2 (SSTDR2\_2)
- SS transmit data register 3\_2 (SSTDR3\_2)
- SS receive data register 0\_2 (SSRDR0\_2)
- SS receive data register 1\_2 (SSRDR1\_2)
- SS receive data register 2\_2 (SSRDR2\_2)
- SS receive data register 3\_2 (SSRDR3\_2)
- SS shift register\_2 (SSTRSR\_2)

### 14.3.1 SS Control Register H (SSCRH)

SSCRH specifies master/slave device selection, bidirectional mode enable, SSO pin output value selection, SSCK pin selection, and  $\overline{\text{SCS}}$  pin selection.

Bit	7	6	5	4	3	2	1	0
Bit Name	MSS	BIDE	—	SOL	SOLP	SCKS	CSS1	CSS0
Initial Value	0	0	0	0	1	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	MSS	0	R/W	<p>Master/Slave Device Select</p> <p>Selects that this module is used in master mode or slave mode. When master mode is selected, transfer clocks are output from the SSCK pin. When the CE bit in SSSR is set, this bit is automatically cleared.</p> <p>0: Slave mode is selected.</p> <p>1: Master mode is selected.</p>
6	BIDE	0	R/W	<p>Bidirectional Mode Enable</p> <p>Selects that both serial data input pin and output pin are used or one of them is used. However, transmission and reception are not performed simultaneously when bidirectional mode is selected. For details, section 14.4.3, Relationship between Data Input/Output Pins and Shift Register.</p> <p>0: Standard mode (two pins are used for data input and output)</p> <p>1: Bidirectional mode (one pin is used for data input and output)</p>
5	—	0	R/W	<p>Reserved</p> <p>This bit is always read as 0. The write value should always be 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
4	SOL	0	R/W	<p>Serial Data Output Value Select</p> <p>The serial data output retains its level of the last bit after completion of transmission. The output level before or after transmission can be specified by setting this bit. When specifying the output level, use the MOV instruction after clearing the SOLP bit to 0. Since writing to this bit during data transmission causes malfunctions, this bit should not be changed.</p> <p>0: Serial data output is changed to low. 1: Serial data output is changed to high.</p>
3	SOLP	1	R/W	<p>SOL Bit Write Protect</p> <p>When changing the output level of serial data, set the SOL bit to 1 or clear the SOL bit to 0 after clearing the SOLP bit to 0 using the MOV instruction.</p> <p>0: Output level can be changed by the SOL bit 1: Output level cannot be changed by the SOL bit. This bit is always read as 1.</p>
2	SCKS	0	R/W	<p>SSCK Pin Select</p> <p>Selects that the SSCK pin functions as a port or a serial clock pin. When the SSCK pin is used as a serial clock pin, this bit must be set to 1.</p> <p>0: Functions as an I/O port. 1: Functions as a serial clock.</p>
1	CSS1	0	R/W	<p><math>\overline{\text{SCS}}</math> Pin Select</p>
0	CSS0	0	R/W	<p>Select that the <math>\overline{\text{SCS}}</math> pin functions as a port or <math>\overline{\text{SCS}}</math> input or output. However, when <math>\text{MSS} = 0</math>, the <math>\overline{\text{SCS}}</math> pin functions as an input pin regardless of the CSS1 and CSS0 settings.</p> <p>00: I/O port 01: Function as <math>\overline{\text{SCS}}</math> input 10: Function as <math>\overline{\text{SCS}}</math> automatic input/output (function as <math>\overline{\text{SCS}}</math> input before and after transfer and output a low level during transfer) 11: Function as <math>\overline{\text{SCS}}</math> automatic output (outputs a high level before and after transfer and outputs a low level during transfer)</p>

### 14.3.2 SS Control Register L (SSCRL)

SSCRL selects operating mode, software reset, and transmit/receive data length.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	SSUMS	SRES	—	—	—	DATS1	DATS0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	R/W	Reserved This bit is always read as 0. The write value should always be 0.
6	SSUMS	0	R/W	Selects transfer mode from SSU mode and clock synchronous mode. 0: SSU mode 1: Clock synchronous mode
5	SRES	0	R/W	Software Reset Setting this bit to 1 forcibly resets the SSU internal sequencer. After that, this bit is automatically cleared. The ORER, TEND, TDRE, RDRF, and CE bits in SSSR and the TE and RE bits in SSER are also initialized. Values of other bits for SSU registers are held. To stop transfer, set this bit to 1 to reset the SSU internal sequencer.
4 to 2	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.
1	DATS1	0	R/W	Transmit/Receive Data Length Select
0	DATS0	0	R/W	Select serial data length. 00: 8 bits 01: 16 bits 10: 32 bits 11: 24 bits

### 14.3.3 SS Mode Register (SSMR)

SSMR selects the MSB first/LSB first, clock polarity, clock phase, and clock rate of synchronous serial communication.

Bit	7	6	5	4	3	2	1	0
Bit Name	MLS	CPOS	CPHS	—	—	CKS2	CKS1	CKS0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	MLS	0	R/W	<b>MSB First/LSB First Select</b> Selects that the serial data is transmitted in MSB first or LSB first. 0: LSB first 1: MSB first
6	CPOS	0	R/W	<b>Clock Polarity Select</b> Selects the SSCK clock polarity. 0: High output in idle mode, and low output in active mode 1: Low output in idle mode, and high output in active mode
5	CPHS	0	R/W	<b>Clock Phase Select (Only for SSU Mode)</b> Selects the SSCK clock phase. 0: Data changes at the first edge. 1: Data is latched at the first edge.

### 14.3.4 SS Enable Register (SSER)

SSER performs transfer/receive control of synchronous serial communication and setting of interrupt enable.

Bit	7	6	5	4	3	2	1	0
Bit Name	TE	RE	—	—	TEIE	TIE	RIE	CEIE
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	TE	0	R/W	Transmit Enable When this bit is set to 1, transmission is enabled.
6	RE	0	R/W	Receive Enable When this bit is set to 1, reception is enabled.
5, 4	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.
3	TEIE	0	R/W	Transmit End Interrupt Enable When this bit is set to 1, a TEI interrupt request is enabled.
2	TIE	0	R/W	Transmit Interrupt Enable When this bit is set to 1, a TXI interrupt request is enabled.
1	RIE	0	R/W	Receive Interrupt Enable When this bit is set to 1, an RXI interrupt request and an OEI interrupt request are enabled.
0	CEIE	0	R/W	Conflict Error Interrupt Enable When this bit is set to 1, a CEI interrupt request is enabled.

### 14.3.5 SS Status Register (SSSR)

SSSR is a status flag register for interrupts.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	ORER	—	—	TEND	TDRE	RDRF	CE
Initial Value	0	0	0	0	0	1	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	—	Reserved This bit is always read as 0. The write value should always be 0.
6	ORER	0	R/W	Overrun Error If the next data is received while RDRF = 1, an overrun error occurs, indicating abnormal termination. SSRDR stores 1-frame receive data before an overrun error occurs and loses data to be received later. While ORER = 1, consecutive serial reception cannot be continued. Serial transmission cannot be continued, either. [Setting condition] When one byte of the next reception is completed with RDRF = 1 [Clearing condition] When writing 0 after reading ORER = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)
5, 4	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3	TEND	1	R	<p>Transmit End</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>When the last bit of transmit data is transmitted while the TENDSTS bit in SSCR2 is cleared to 0 and the TDRE bit is set to 1</li> <li>After the last bit of transmit data is transmitted while the TENDSTS bit in SSCR2 is set to 1 and the TDRE bit is set to 1</li> </ul> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>When writing 0 after reading TEND = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> <li>When writing data to SSTDR</li> </ul>
2	TDRE	1	R/W	<p>Transmit Data Empty</p> <p>Indicates whether or not SSTDR contains transmit data.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>When the TE bit in SSER is 0</li> <li>When data is transferred from SSTDR to SSTRSR and SSTDR is ready to be written to.</li> </ul> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>When writing 0 after reading TDRE = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> <li>When writing data to SSTDR with TE = 1</li> </ul>
1	RDRF	0	R/W	<p>Receive Data Register Full</p> <p>Indicates whether or not SSRDR contains receive data.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>When receive data is transferred from SSTRSR to SSRDR after successful serial data reception</li> </ul> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>When writing 0 after reading RDRF = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> <li>When reading receive data from SSRDR</li> </ul>

Bit	Bit Name	Initial Value	R/W	Description
0	CE	0	R/W	<p>Conflict/Incomplete Error</p> <p>Indicates that a conflict error has occurred when 0 is externally input to the <math>\overline{\text{SCS}}</math> pin with <math>\text{SSUMS} = 0</math> (SSU mode) and <math>\text{MSS} = 1</math> (master mode).</p> <p>If the <math>\overline{\text{SCS}}</math> pin level changes to 1 with <math>\text{SSUMS} = 0</math> (SSU mode) and <math>\text{MSS} = 0</math> (slave mode), an incomplete error occurs because it is determined that a master device has terminated the transfer. Data reception does not continue while the CE bit is set to 1. Serial transmission also does not continue. Reset the SSU internal sequencer by setting the SRES bit in SSCRL to 1 before resuming transfer after incomplete error.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• When a low level is input to the <math>\overline{\text{SCS}}</math> pin in master mode (the MSS bit in SSCRH is set to 1)</li> <li>• When the <math>\overline{\text{SCS}}</math> pin is changed to 1 during transfer in slave mode (the MSS bit in SSCRH is cleared to 0)</li> </ul> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>• When writing 0 after reading <math>\text{CE} = 1</math> (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> </ul>

### 14.3.6 SS Control Register 2 (SSCR2)

SSCR2 is a register that enables/disables the open-drain outputs of the SSO, SSI, SSCK, and  $\overline{\text{SCS}}$  pins, selects the assert timing of the  $\overline{\text{SCS}}$  pin, data output timing of the SSO pin, and set timing of the TEND bit.

Bit	7	6	5	4	3	2	1	0

4	TENDSTS	0	R/W	<p>Selects the timing of setting the TEND bit (valid in SSU and master mode).</p> <p>0: Sets the TEND bit when the last bit is being transmitted 1: Sets the TEND bit after the last bit is transmitted</p>

Bit	Bit Name	Initial Value	R/W	Description
3	SCSATS	0	R/W	<p>Selects the assertion timing of the <math>\overline{\text{SCS}}</math> pin (valid in SSU and master mode).</p> <p>0: Min. values of <math>t_{\text{LEAD}}</math> and <math>t_{\text{LAG}}</math> are <math>1/2 \times t_{\text{SUcyc}}</math></p> <p>1: Min. values of <math>t_{\text{LEAD}}</math> and <math>t_{\text{LAG}}</math> are <math>3/2 \times t_{\text{SUcyc}}</math></p>
2	SSODTS	0	R/W	<p>Selects the data output timing of the SSO pin (valid in SSU and master mode)</p> <p>0: While BIDE = 0, MSS = 1, and TE = 1 or while BIDE = 1, TE = 1, and RE = 0, the SSO pin outputs data</p> <p>1: While BIDE = 0, MSS = 1, and TE = 1 or while BIDE = 1, TE = 1, and RE = 0, the SSO pin outputs data while the SCS pin is driven low</p>
1, 0	—	All 0	R/W	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>

### 14.3.7 SS Transmit Data Registers 0 to 3 (SSTDR0 to SSTDR3)

SSTDR is an 8-bit register that stores transmit data. When 8-bit data length is selected by bits DATS1 and DATS0 in SSCRL, SSTDR0 is valid. When 16-bit data length is selected, SSTDR0 and SSTDR1 are valid. When 24-bit data length is selected, SSTDR0, SSTDR1, and SSTDR2 are valid. When 32-bit data length is selected, SSTDR0 to SSTDR3 are valid. Be sure not to access to invalid SSTDRs.

When the SSU detects that SSTRSR is empty, it transfers the transmit data written in SSTDR to SSTRSR and starts serial transmission. If the next transmit data has already been written to SSTDR during serial transmission, the SSU performs consecutive serial transmission.

Although SSTDR can always be read from or written to by the CPU and DMAC, to achieve reliable serial transmission, write transmit data to SSTDR after confirming that the TDRE bit in SSSR is set to 1.

3	Invalid	Invalid	Valid	Invalid

### 14.3.8 SS Receive Data Registers 0 to 3 (SSRDR0 to SSRDR3)

SSRDR is an 8-bit register that stores receive data. When 8-bit data length is selected by bits DATS1 and DATS0 in SSCRL, SSRDR0 is valid. When 16-bit data length is selected, SSRDR0 and SSRDR1 are valid. When 24-bit data length is selected, SSRDR0, SSRDR1, and SSRDR2 are valid. When 32-bit data length is selected, SSRDR0 to SSRDR3 are valid. Be sure not to access to invalid SSRDR.

When the SSU has received 1-byte data, it transfers the received serial data from SSTRSR to SSRDR where it is stored. After this, SSTRSR is ready for reception. Since SSTRSR and SSRDR function as a double buffer in this way, consecutive receive operations can be performed.

Read SSRDR after confirming that the RDRF bit in SSSR is set to 1.

SSRDR is a read-only register, therefore, cannot be written to by the CPU.

2	Invalid	Invalid	Valid	Valid
3	Invalid	Invalid	Valid	Invalid

### 14.3.9 SS Shift Register (SSTRSR)

SSTRSR is a shift register that transmits and receives serial data.

When data is transferred from SSTDR to SSTRSR, bit 0 of transmit data is bit 0 in the SSTDR contents (MLS = 0: LSB first communication) and is bit 7 in the SSTDR contents (MLS = 1: MSB first communication). The SSU transfers data from the LSB (bit 0) in SSTRSR to the SSO pin to perform serial data transmission.

In reception, the SSU sets serial data that has been input via the SSI pin in SSTRSR from the LSB (bit 0). When 1-byte data has been received, the SSTRSR contents are automatically transferred to SSRDR. SSTRSR cannot be directly accessed by the CPU.

## 14.4 Operation

### 14.4.1 Transfer Clock

A transfer clock can be selected from eight internal clocks and an external clock. When using this module, set the SCKS bit in SSCRH to 1 to select the SSCK pin as a serial clock. When the MSS bit in SSCRH is 1, an internal clock is selected and the SSCK pin is used as an output pin. When transfer is started, the clock with the transfer rate set by bits CKS2 to CKS0 in SSMR is output from the SSCK pin. When MSS = 0, an external clock is selected and the SSCK pin is used as an input pin.

### 14.4.2 Relationship of Clock Phase, Polarity, and Data

The relationship of clock phase, polarity, and transfer data depends on the combination of the CPOS and CPHS bits in SSMR. Figure 14.2 shows the relationship. When SSUMS = 1, the CPHS setting is invalid although the CPOS setting is valid.

Setting the MLS bit in SSMR selects that MSB or LSB first communication. When MLS = 0, data is transferred from the LSB to the MSB. When MLS = 1, data is transferred from the MSB to the LSB.

**Figure 14.2 Relationship of Clock Phase, Polarity, and Data**

### 14.4.3 Relationship between Data Input/Output Pins and Shift Register

The connection between data input/output pins and the SS shift register (SSTRSR) depends on the combination of the MSS and BIDE bits in SSCRH and the SSUMS bit in SSCRL. Figure 14.3 shows the relationship.

The SSU transmits serial data from the SSO pin and receives serial data from the SSI pin when operating with BIDE = 0 and MSS = 1 (standard, master mode) (see figure 14.3 (1)). The SSU transmits serial data from the SSI pin and receives serial data from the SSO pin when operating with BIDE = 0 and MSS = 0 (standard, slave mode) (see figure 14.3 (2)).

The SSU transmits and receives serial data from the SSO pin regardless of master or slave mode when operating with BIDE = 1 (bidirectional mode) (see figures 14.3 (3) and (4)).

However, even if both the TE and RE bits are set to 1, transmission and reception are not performed simultaneously. Either the TE or RE bit must be selected.

The SSU transmits serial data from the SSO pin and receives serial data from the SSI pin when operating with SSUMS = 1. The SCK pin outputs the internal clock when MSS = 1 and function as an input pin when MSS = 0 (see figures 14.3 (5) and (6)).

**Figure 14.3 Relationship between Data Input/Output Pins and the Shift Register**

#### 14.4.4 Communication Modes and Pin Functions

The SSU switches the input/output pin (SSI, SSO, SSCK, and  $\overline{\text{SCS}}$ ) functions according to the communication modes and register settings. When a pin is used as an input pin, set the corresponding bit in the input buffer control register (ICR) to 1. The relationship of communication modes and input/output pin functions are shown in tables 14.4 to 14.6.

**Table 14.4 Communication Modes and Pin States of SSI and SSO Pins**

Communication Mode	Register Setting					Pin State		
	SSUMS	BIDE	MSS	TE	RE	SSI	SSO	
SSU communication mode	0	0	0	0	1	—	Input	
				1	0	Output	—	
					1	Output	Input

			1	1	Output
Clock synchronous communication mode	1	×	×	×	—

[Legend]

×: Don't care

—: Not used as SSU pin

### 14.4.5 SSU Mode

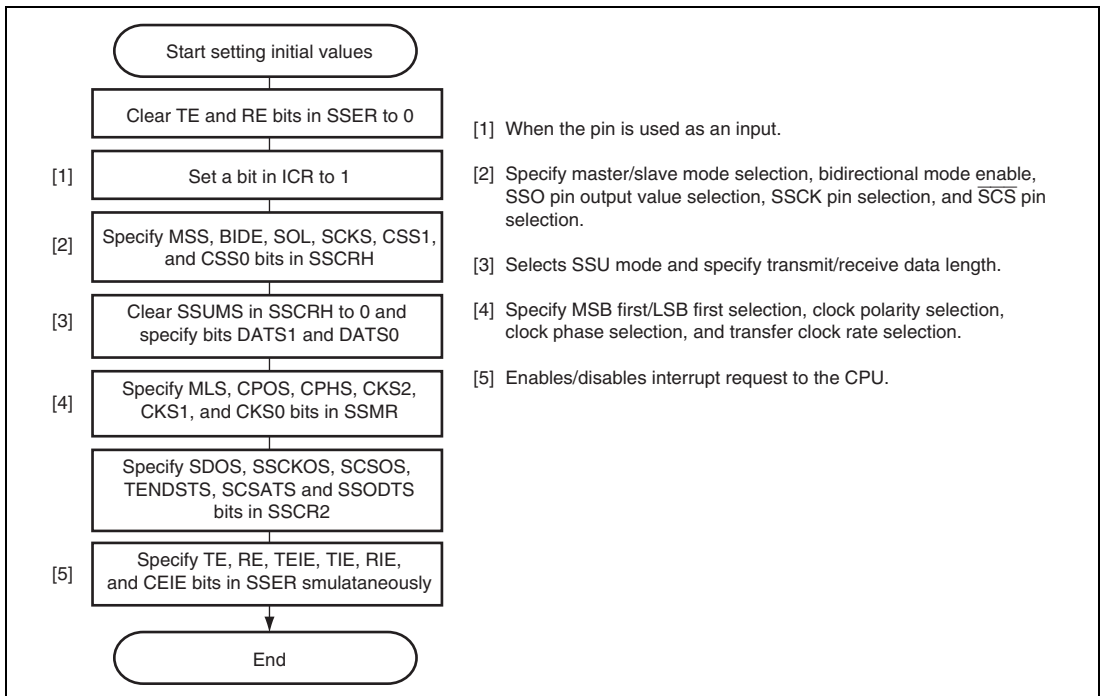

In SSU mode, data communications are performed via four lines: clock line (SSCK), data input line (SSI or SSO), data output line (SSI or SSO), and chip select line ( $\overline{\text{SCS}}$ ).

In addition, the SSU supports bidirectional mode in which a single pin functions as data input and data output lines.

#### (1) Initial Settings in SSU Mode

Figure 14.4 shows an example of the initial settings in SSU mode. Before data transfer, clear both the TE and RE bits in SSER to 0 to set the initial values.

**Note:** Before changing operating modes and communications formats, clear both the TE and RE bits to 0. Although clearing the TE bit to 0 sets the TDRE bit to 1, clearing the RE bit to 0 does not change the values of the RDRF and ORER bits and SSRDR. Those bits retain the previous values.

**Figure 14.4 Example of Initial Settings in SSU Mode**

## (2) Data Transmission

Figure 14.5 shows an example of transmission operation, and figure 14.6 shows a flowchart example of data transmission.

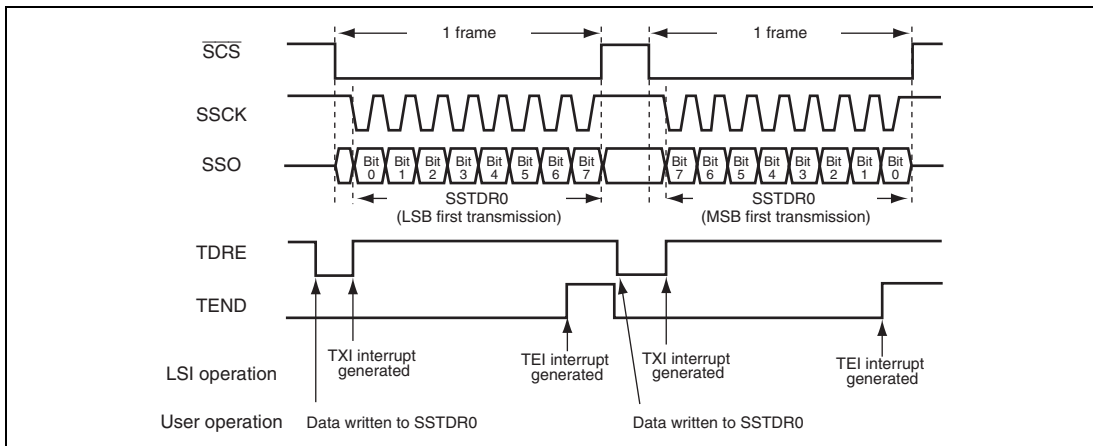

When transmitting data, the SSU operates as shown below.

In master mode, the SSU outputs a transfer clock and data. In slave mode, when a low level signal is input to the SCS pin and a transfer clock is input to the SSCK pin, the SSU outputs data in synchronization with the transfer clock.

Writing transmit data to SSTDR after the TE bit is set to 1 clears the TDRE bit in SSSR to 0, and the SSTDR contents are transferred to SSTRSR. After that, the SSU sets the TDRE bit to 1 and starts transmission. At this time, if the TIE bit in SSER is set to 1, a TXI interrupt is generated.

When 1-frame data has been transferred with TDRE = 0, the SSTDR contents are transferred to SSTRSR to start the next frame transmission. When the 8th bit of transmit data has been transferred with TDRE = 1, the TEND bit in SSSR is set to 1 and the state is retained. At this time, if the TEIE bit is set to 1, a TEI interrupt is generated. After transmission, the output level of the SSCK pin is fixed high when CPOS = 0 and low when CPOS = 1.

While the ORER bit in SSSR is set to 1, transmission is not performed. Check that the ORER bit is cleared to 0.

**Figure 14.5 Example of Transmission Operation (SSU Mode)**

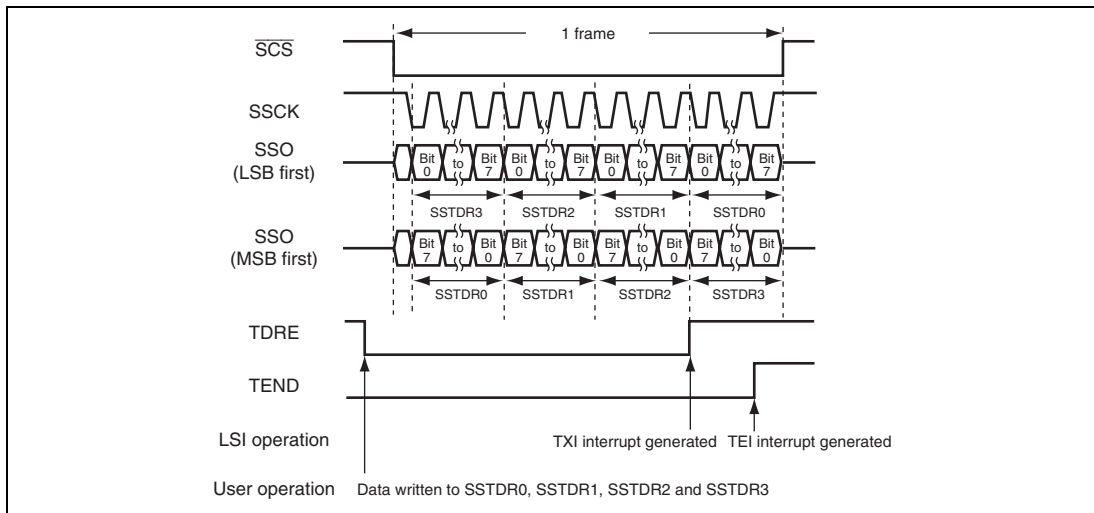

**When 8-bit data length is selected (SSTD0 is valid) with CPOS = 0 and CPHS = 0 (1)**

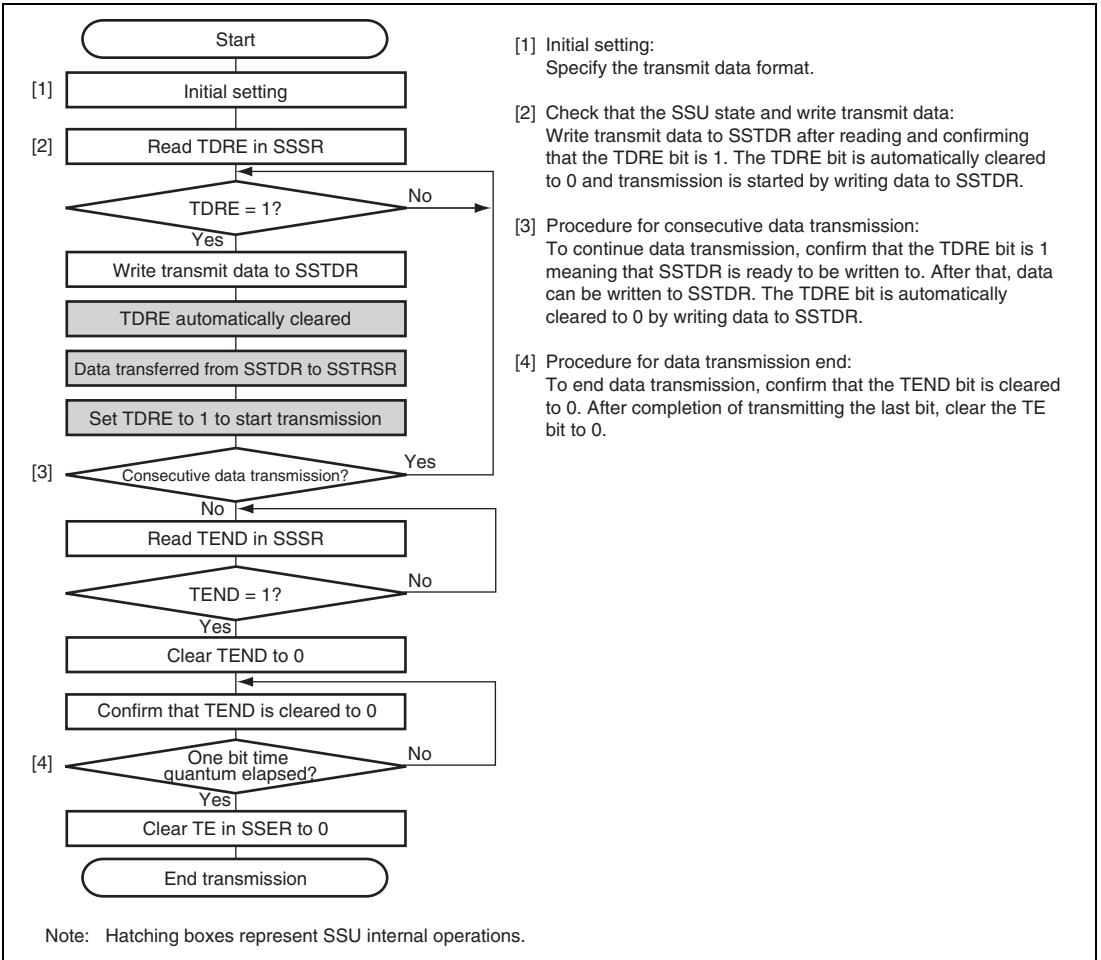

**Figure 14.5 Example of Transmission Operation (SSU Mode) When 16-bit data length is selected (SSTD0 and SSTD1 are valid) with CPOS = 0 and CPHS = 0 (2)**

**Figure 14.5 Example of Transmission Operation (SSU Mode) When 24-bit data length is selected (SSTDR0, SSTDR1, and SSTDR2 are valid) with CPOS = 0 and CPHS = 0 (3)**

**Figure 14.5 Example of Transmission Operation (SSU Mode) When 32-bit data length is selected (SSTDR0, SSTDR1, SSTDR2 and SSTDR3 are valid) with CPOS = 0 and CPHS = 0 (4)**

**Figure 14.6 Flowchart Example of Data Transmission (SSU Mode)**

### (3) Data Reception

Figure 14.7 shows an example of reception operation, and figure 14.8 shows a flowchart example of data reception. When receiving data, the SSU operates as shown below.

After setting the RE bit to 1 and dummy-reading SSRDR, the SSU starts data reception.

In master mode, the SSU outputs a transfer clock and receives data. In slave mode, when a low level signal is input to the  $\overline{SCS}$  pin and a transfer clock is input to the SSCK pin, the SSU receives data in synchronization with the transfer clock.

When 1-frame data has been received, the RDRF bit in SSSR is set to 1 and the receive data is stored in SSRDR. At this time, if the RIE bit in SSER is set to 1, an RXI interrupt is generated. The RDRF bit is automatically cleared to 0 by reading SSRDR.

When the RDRF bit has been set to 1 at the 8th rising edge of the transfer clock, the ORER bit in SSSR is set to 1. This indicates that an overrun error (OEI) has occurred. At this time, data reception is stopped. While the ORER bit in SSSR is set to 1, reception is not performed. To resume the reception, clear the ORER bit to 0.

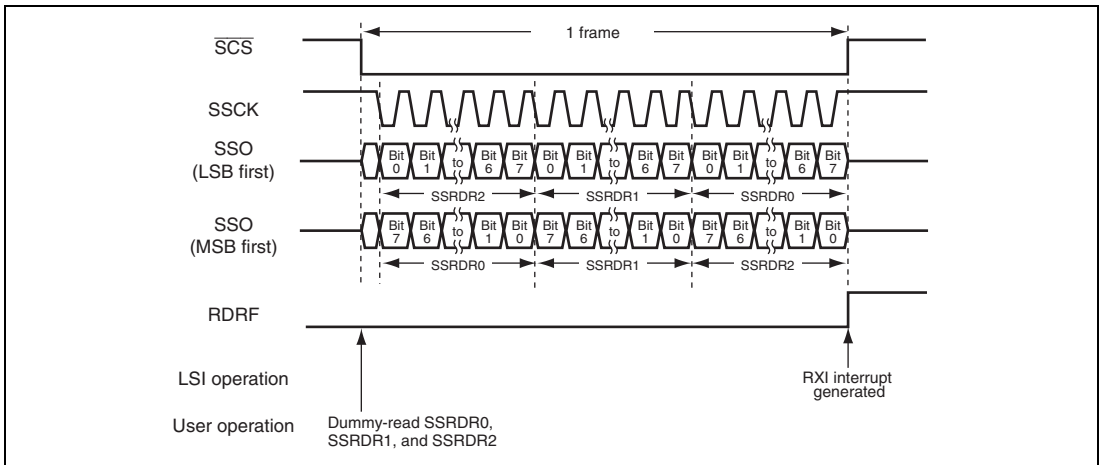

**Figure 14.7 Example of Reception Operation (SSU Mode)**

**When 8-bit data length is selected (SSRDR0 is valid) with CPOS = 0 and CPHS = 0 (1)**

**Figure 14.7 Example of Reception Operation (SSU Mode) When 16-bit data length is selected ( $SSRDR0$  and  $SSRDR1$  are valid) with  $CPOS = 0$  and  $CPHS = 0$  (2)**

**Figure 14.7 Example of Reception Operation (SSU Mode) When 24-bit data length is selected ( $SSRDR0$ ,  $SSRDR1$ , and  $SSRDR2$  are valid) with  $CPOS = 0$  and  $CPHS = 0$  (3)**

**Figure 14.7 Example of Reception Operation (SSU Mode)**

**When 32-bit data length is selected (SSRDR0, SSRDR1, SSRDR2 and SSRDR3 are valid) with CPOS = 0 and CPHS = 0 (4)**

- [1] Initial setting:  
Specify the receive data format.
- [2] Start reception:  
When SSRDR is dummy-read with RE = 1, reception is started.
- [3], [6] Receive error processing:  
When a receive error occurs, execute the designated error processing after reading the ORER bit in SSSR. After that, clear the ORER bit to 0. While the ORER bit is set to 1, transmission or reception is not resumed.
- [4] To continue single reception:  
When continuing single reception, wait for time of  $t_{SUcyc}$  while the RDRF flag is set to 1 and then read receive data in SSRDR.  
The next single reception starts after reading receive data in SSRDR.
- [5] To complete reception:  
To complete reception, read receive data after clearing the RE bit to 0. When reading SSRDR without clearing the RE bit, reception is resumed.

**Figure 14.8 Flowchart Example of Data Reception (SSU Mode)**

#### (4) Data Transmission/Reception

Figure 14.9 shows a flowchart example of simultaneous transmission/reception. The data transmission/reception is performed combining the data transmission and data reception as mentioned above. The data transmission/reception is started by writing transmit data to SSTDR with  $TE = RE = 1$ .

Before switching transmission mode ( $TE = 1$ ) or reception mode ( $RE = 1$ ) to transmission/reception mode ( $TE = RE = 1$ ), clear the TE and RE bits to 0. When starting the transfer, confirm that the TEND, RDRF, and ORER bits are cleared to 0 before setting the TE or RE bit to 1.

**Figure 14.9 Flowchart Example of Simultaneous Transmission/Reception (SSU Mode)**

### 14.4.6 $\overline{\text{SCS}}$ Pin Control and Conflict Error

When bits CSS1 and CSS0 in SSCRH are specified to B'10 and the SSUMS bit in SSCRL is cleared to 0, the  $\overline{\text{SCS}}$  pin functions as an input (Hi-Z) to detect conflict error. The conflict detection period is from setting the MSS bit in SSCRH to 1 to starting serial transfer and after transfer ends. When a low level signal is input to the  $\overline{\text{SCS}}$  pin within the period, a conflict error occurs. At this time, the CE bit in SSSR is set to 1 and the MSS bit is cleared to 0.

Note: While the CE bit is set to 1, transmission or reception is not resumed. Clear the CE bit to 0 before resuming the transmission or reception.

**Figure 14.10 Conflict Error Detection Timing (Before Transfer)**

**Figure 14.11 Conflict Error Detection Timing (After Transfer End)**

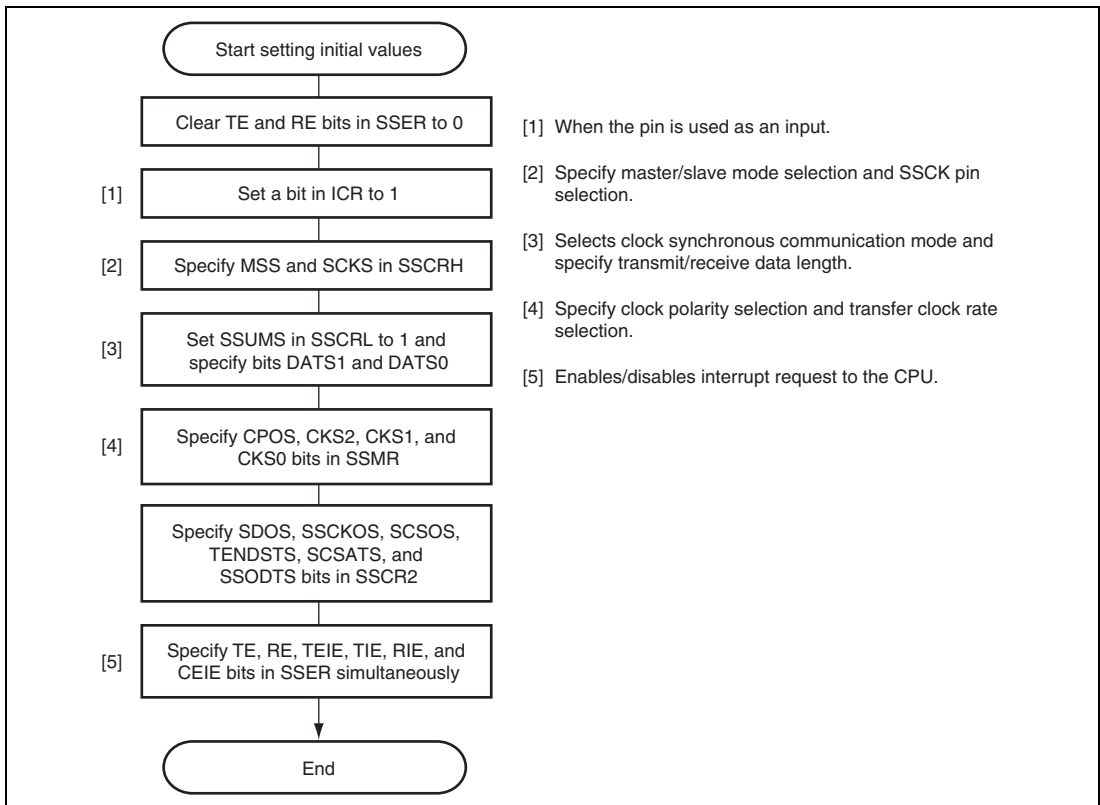

### 14.4.7 Clock Synchronous Communication Mode

In clock synchronous communication mode, data communications are performed via three lines: clock line (SSCK), data input line (SSI), and data output line (SSO).

#### (1) Initial Settings in Clock Synchronous Communication Mode

Figure 14.12 shows an example of the initial settings in clock synchronous communication mode. Before data transfer, clear both the TE and RE bits in SSER to 0 to set the initial values.

Note: Before changing operating modes and communications formats, clear both the TE and RE bits to 0. Although clearing the TE bit to 0 sets the TDRE bit to 1, clearing the RE bit to 0 does not change the values of the RDRF and ORER bits and SSRDR. Those bits retain the previous values.

**Figure 14.12 Example of Initial Settings in Clock Synchronous Communication Mode**

## (2) Data Transmission

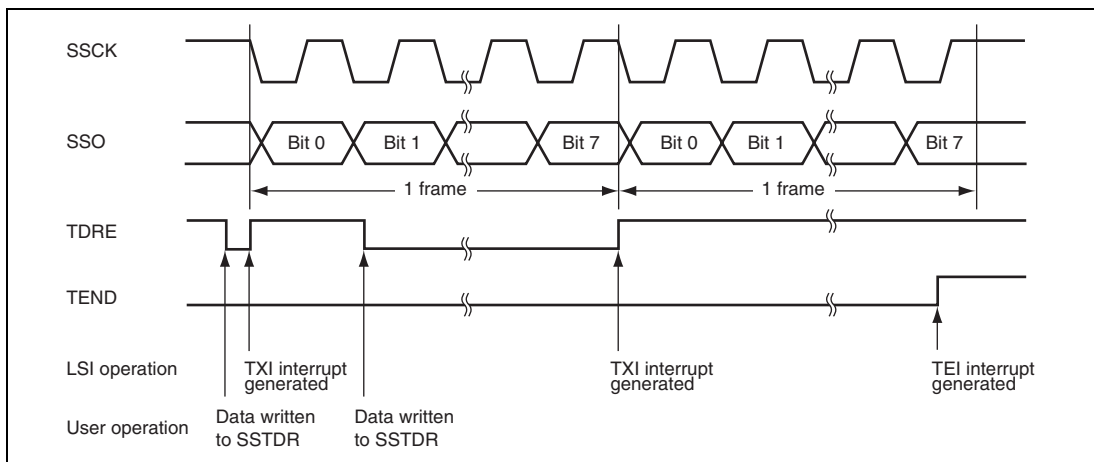

Figure 14.13 shows an example of transmission operation, and figure 14.14 shows a flowchart example of data transmission. When transmitting data in clock synchronous communication mode, the SSU operates as shown below.

In master mode, the SSU outputs a transfer clock and data. In slave mode, when a transfer clock is input to the SSCK pin, the SSU outputs data in synchronization with the transfer clock.

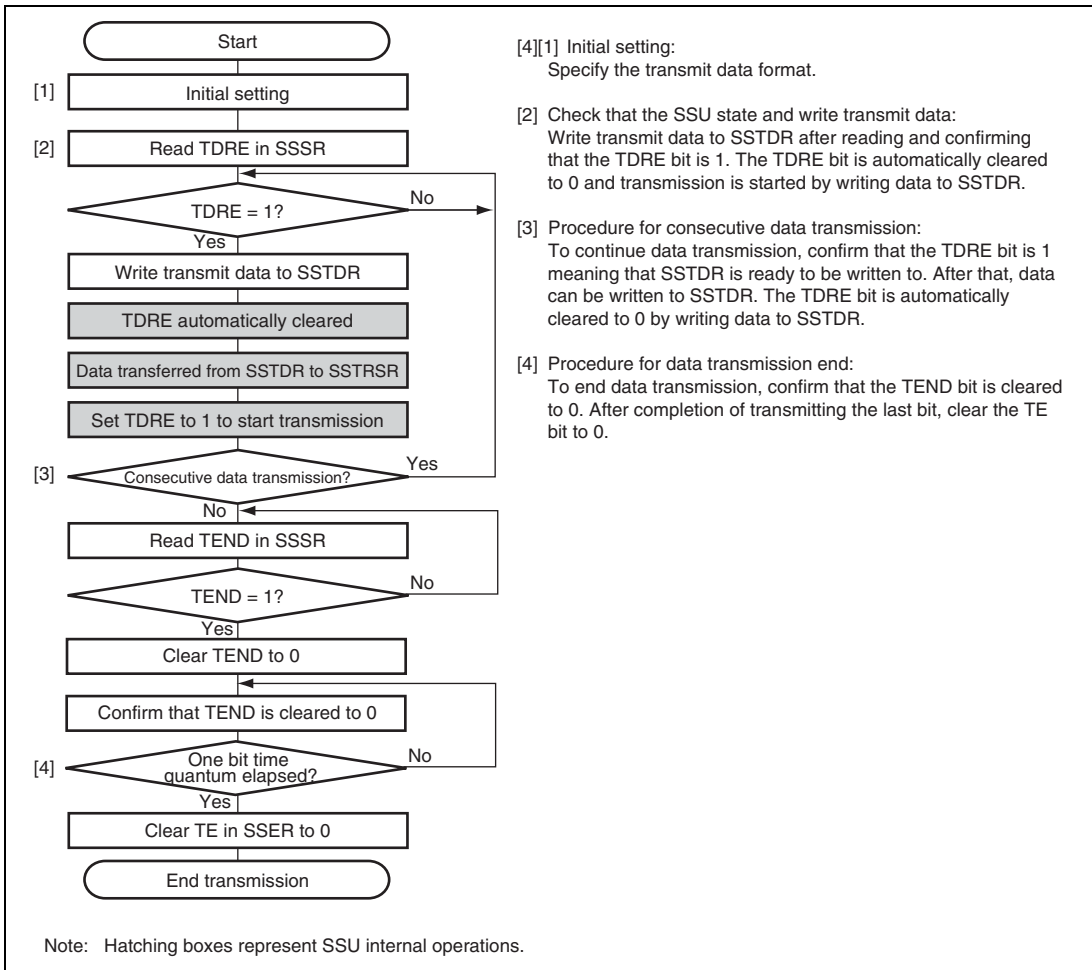

Writing transmit data to SSTDR after the TE bit is set to 1 clears the TDRE bit in SSSR to 0, and the SSTDR contents are transferred to SSTRSR. After that, the SSU sets the TDRE bit to 1 and starts transmission. At this time, if the TIE bit in SSER is set to 1, a TXI interrupt is generated.

When 1-frame data has been transferred with TDRE = 0, the SSTDR contents are transferred to SSTRSR to start the next frame transmission. When the 8th bit of transmit data has been transferred with TDRE = 1, the TEND bit in SSSR is set to 1 and the state is retained. At this time, if the TEIE bit is set to 1, a TEI interrupt is generated.

While the ORER bit in SSSR is set to 1, transmission is not performed. Check that the ORER bit is cleared to 0.

**Figure 14.13 Example of Transmission Operation  
(Clock Synchronous Communication Mode)**

**Figure 14.14 Flowchart Example of Transmission Operation (Clock Synchronous Communication Mode)**

### (3) Data Reception

Figure 14.15 shows an example of reception operation, and figure 14.16 shows a flowchart example of data reception. When receiving data, the SSU operates as shown below.

After setting the RE bit in SSER to 1, the SSU starts data reception.

In master mode, the SSU outputs a transfer clock and receives data. In slave mode, when a transfer clock is input to the SSCK pin, the SSU receives data in synchronization with the transfer clock.

When 1-frame data has been received, the RDRF bit in SSSR is set to 1 and the receive data is stored in SSRDR. At this time, if the RIE bit is set to 1, an RXI interrupt is generated. The RDRF bit is automatically cleared to 0 by reading SSRDR.

When the RDRF bit has been set to 1 at the 8th rising edge of the transfer clock, the ORER bit in SSSR is set to 1. This indicates that an overrun error (OEI) has occurred. At this time, data reception is stopped. While the ORER bit in SSSR is set to 1, reception is not performed. To resume the reception, clear the ORER bit to 0.

**Figure 14.15 Example of Reception Operation  
(Clock Synchronous Communication Mode)**

**Figure 14.16 Flowchart Example of Data Reception (Clock Synchronous Communication Mode)**

#### (4) Data Transmission/Reception

Figure 14.17 shows a flowchart example of simultaneous transmission/reception. The data transmission/reception is performed combining the data transmission and data reception as mentioned above. The data transmission/reception is started by writing transmit data to SSTDR with  $TE = RE = 1$ .

Before switching transmission mode ( $TE = 1$ ) or reception mode ( $RE = 1$ ) to transmission/reception mode ( $TE = RE = 1$ ), clear the TE and RE bits to 0. When starting the transfer, confirm that the TEND, RDRF, and ORER bits are cleared to 0 before setting the TE or RE bits to 1.

**Figure 14.17 Flowchart Example of Simultaneous Transmission/Reception (Clock Synchronous Communication Mode)**

## 14.5 Interrupt Requests

The SSU interrupt requests are an overrun error, a conflict error, a receive data register full, transmit data register empty, and a transmit end interrupts. Of these interrupt sources, a receive data register full, a transmit data register empty, and a transmit end interrupts can activate the DMAC for data transfer.

Since both an overrun error and a conflict error interrupts are allocated to the SSERI vector address, and both a transmit data register empty and a transmit end interrupts are allocated to the SSTXI vector address, the interrupt source should be decided by their flags. Table 14.7 lists the interrupt sources.

When an interrupt condition shown in table 14.7 is satisfied, an interrupt is requested. Clear the interrupt source by CPU or DMAC data transfer.

**Table 14.7 Interrupt Sources**

Channel	Abbreviation	Interrupt Source	Symbol	Interrupt Condition	DMAC Activation
0	SSERI0	Overrun error	OEI0	$(RIE = 1) \bullet (ORER = 1)$	—
		Conflict error	CEI0	$(CEIE = 1) \bullet (CE = 1)$	—
	SSRXI0	Receive data register full	RXI0	$(RIE = 1) \bullet (RDRF = 1)$	Yes
	SSTXI0	Transmit data register empty	TXI0	$(TIE = 1) \bullet (TDRE = 1)$	Yes
		Transmit end	TEI0	$(TEIE = 1) \bullet (TEND = 1)$	Yes
1	SSERI1	Overrun error	OEI1	$(RIE = 1) \bullet (ORER = 1)$	—
		Conflict error	CEI1	$(CEIE = 1) \bullet (CE = 1)$	—
	SSRXI1	Receive data register full	RXI1	$(RIE = 1) \bullet (RDRF = 1)$	Yes
	SSTXI1	Transmit data register empty	TXI1	$(TIE = 1) \bullet (TDRE = 1)$	Yes
		Transmit end	TEI1	$(TEIE = 1) \bullet (TEND = 1)$	Yes
2	SSERI2	Overrun error	OEI2	$(RIE = 1) \bullet (ORER = 1)$	—
		Conflict error	CEI2	$(CEIE = 1) \bullet (CE = 1)$	—
	SSRXI2	Receive data register full	RXI2	$(RIE = 1) \bullet (RDRF = 1)$	Yes
	SSTXI2	Transmit data register empty	TXI2	$(TIE = 1) \bullet (TDRE = 1)$	Yes
		Transmit end	TEI2	$(TEIE = 1) \bullet (TEND = 1)$	Yes

## **14.6 Usage Note**

### **14.6.1 Setting of Module Stop Mode**

The SSU can be enabled/disabled by setting the module stop control register setting and is disabled by the initial value. Canceling module stop mode enables to access the SSU register. For details, see section19, Power-Down Modes.

## Section 15 A/D Converter

This LSI includes two units (unit 0 and unit 1) of successive approximation type 10-bit A/D converters that allow up to 16 analog input channels to be selected.

Figures 15.1 and 15.2 are block diagrams for unit 0 and unit 1, respectively.

This section describes unit 0, which has the same functions as the other unit.

### 15.1 Features

- 10-bit resolution
- 16 input channels (eight channels for unit 0 and eight channels for unit 1)
- Conversion time: 7.4  $\mu$ s per channel (at 35-MHz operation)
- Two kinds of operating modes
  - Single mode: Single-channel A/D conversion
  - Scan mode: Continuous A/D conversion on 1 to 4 channels, or 1 to 8 channels
- 16 data registers (eight registers for unit 0 and eight registers for unit 1)  
A/D conversion results are held in a 16-bit data register for each channel
- Sample and hold function
- Three types of conversion start  
Conversion can be started by software, a conversion start trigger by the 16-bit timer pulse unit (TPU), or an external trigger signal.
- Interrupt source  
A/D conversion end interrupt (ADI) request can be generated.
- Module stop mode can be set

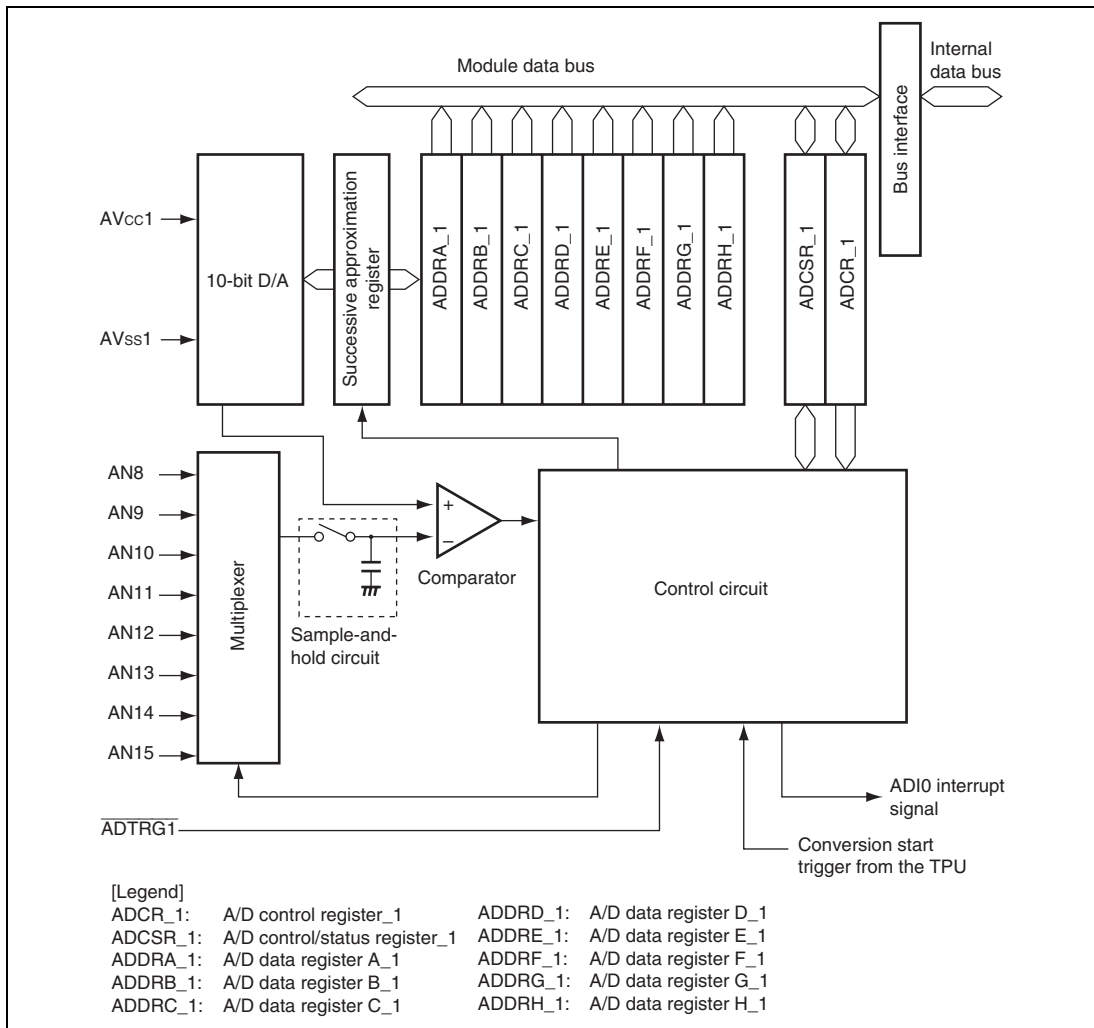

Figure 15.1 Block Diagram of A/D Converter (Unit 0/AD\_0)

**Figure 15.2 Block Diagram of A/D Converter (Unit 1/AD\_1)**

## 15.2 Input/Output Pins

Table 15.1 shows the pin configuration of the A/D converter.

**Table 15.1 Pin Configuration**

Unit	Abbr.	Pin Name	Symbol	I/O	Function
0	AD_0	Analog input pin 0	AN0	Input	Analog inputs
		Analog input pin 1	AN1	Input	
		Analog input pin 2	AN2	Input	
		Analog input pin 3	AN3	Input	
		Analog input pin 4	AN4	Input	
		Analog input pin 5	AN5	Input	
		Analog input pin 6	AN6	Input	
		Analog input pin 7	AN7	Input	
		A/D external trigger input pin 0	ADTRG0	Input	External trigger input for starting A/D conversion
		Analog power supply pin 0	AV <sub>CC0</sub>	Input	Analog block power supply
1	AD_1	Analog input pin 8	AN8	Input	Analog inputs
		Analog input pin 9	AN9	Input	
		Analog input pin 10	AN10	Input	
		Analog input pin 11	AN11	Input	
		Analog input pin 12	AN12	Input	
		Analog input pin 13	AN13	Input	
		Analog input pin 14	AN14	Input	
		Analog input pin 15	AN15	Input	
		A/D external trigger input pin 1	ADTRG1	Input	External trigger input for starting A/D conversion
		Analog power supply pin 1	AV <sub>CC1</sub>	Input	Analog block power supply
Common		Analog ground pin	AV <sub>SS</sub>	Input	Analog block ground

## 15.3 Register Descriptions

The A/D converter has the following registers.

The registers for unit 0 (A/D\_0) and unit 1 (A/D\_1) have the same functions. In this descriptions, AN8 to AN15 correspond to AN0 to AN7.

- Unit 0 (A/D\_0)
  - A/D data register A\_0 (ADDRA\_0)
  - A/D data register B\_0 (ADDRB\_0)
  - A/D data register C\_0 (ADDRC\_0)
  - A/D data register D\_0 (ADDRD\_0)
  - A/D data register E\_0 (ADDRE\_0)
  - A/D data register F\_0 (ADDRF\_0)
  - A/D data register G\_0 (ADDRG\_0)
  - A/D data register H\_0 (ADDRH\_0)
  - A/D control/status register\_0 (ADCSR\_0)
  - A/D control register\_0 (ADCR\_0)
  
- Unit 1 (A/D\_1)
  - A/D data register A\_1 (ADDRA\_1)
  - A/D data register B\_1 (ADDRB\_1)
  - A/D data register C\_1 (ADDRC\_1)
  - A/D data register D\_1 (ADDRD\_1)
  - A/D data register E\_1 (ADDRE\_1)
  - A/D data register F\_1 (ADDRF\_1)
  - A/D data register G\_1 (ADDRG\_1)
  - A/D data register H\_1 (ADDRH\_1)
  - A/D control/status register\_1 (ADCSR\_1)
  - A/D control register\_1 (ADCR\_1)

### 15.3.1 A/D Data Registers A to H (ADDRA to ADDRH)

There are eight 16-bit read-only ADDR registers, ADDRA to ADDRH, used to store the results of A/D conversion. The ADDR registers, which store a conversion result for each channel, are shown in table 15.2.

The converted 10-bit data is stored in bits 15 to 6. The lower 6-bit data is always read as 0.

The data bus between the CPU and the A/D converter has a 16-bit width. The data can be read directly from the CPU. ADDR must not be accessed in 8-bit units and must be accessed in 16-bit units.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit Name											—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

**Table 15.2 Analog Input Channels and Corresponding ADDR Registers**

Analog Input Channel	A/D Data Register Which Stores Conversion Result
AN0	ADDRA
AN1	ADDRB
AN2	ADDRC
AN3	ADDRD
AN4	ADDRE
AN5	ADDRF
AN6	ADDRG
AN7	ADDRH

### 15.3.2 A/D Control/Status Register (ADCSR)

ADCSR controls A/D conversion operations.

Bit	7	6	5	4	3	2	1	0
Bit Name	ADF	ADIE	ADST	—	CH3	CH2	CH1	CH0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/(W)*	R/W	R/W	R	R/W	R/W	R/W	R/W

Note: \* Only 0 can be written to this bit, to clear the flag.

Bit	Bit Name	Initial Value	R/W	Description
7	ADF	0	R/(W)*	<p><b>A/D End Flag</b></p> <p>A status flag that indicates the end of A/D conversion.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>When A/D conversion ends in single mode</li> <li>When A/D conversion ends on all specified channels in scan mode</li> </ul> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>When 0 is written after reading ADF = 1 (When the CPU is used to clear this flag by writing 0 while the corresponding interrupt is enabled, be sure to read the flag after writing 0 to it.)</li> <li>When the DMAC is activated by an ADI interrupt and ADDR is read</li> </ul>
6	ADIE	0	R/W	<p><b>A/D Interrupt Enable</b></p> <p>When this bit is set to 1, ADI interrupts by ADF are enabled.</p>
5	ADST	0	R/W	<p><b>A/D Start</b></p> <p>Clearing this bit to 0 stops A/D conversion, and the A/D converter enters wait state.</p> <p>Setting this bit to 1 starts A/D conversion. In single mode, this bit is cleared to 0 automatically when A/D conversion on the specified channel ends. In scan mode, A/D conversion continues sequentially on the specified channels until this bit is cleared to 0 by software or a reset.</p>

Bit	Bit Name	Initial Value	R/W	Description
4	—	0	R	Reserved This is a read-only bit and cannot be modified.
3	CH3	0	R/W	Channel Select 3 to 0
2	CH2	0	R/W	Selects analog input together with bits SCANE and SCANS in ADCR.
1	CH1	0	R/W	
0	CH0	0	R/W	<ul style="list-style-type: none"> <li>• When SCANE = 0 and SCANS = X               <ul style="list-style-type: none"> <li>0000: AN0</li> <li>0001: AN1</li> <li>0010: AN2</li> <li>0011: AN3</li> <li>0100: AN4</li> <li>0101: AN5</li> <li>0110: AN6</li> <li>0111: AN7</li> <li>1XXX: Setting prohibited</li> </ul> </li> <li>• When SCANE = 1 and SCANS = 0               <ul style="list-style-type: none"> <li>0000: AN0</li> <li>0001: AN0 and AN1</li> <li>0010: AN0 to AN2</li> <li>0011: AN0 to AN3</li> <li>0100: AN4</li> <li>0101: AN4 and AN5</li> <li>0110: AN4 to AN6</li> <li>0111: AN4 to AN7</li> <li>1XXX: Setting prohibited</li> </ul> </li> <li>• When SCANE = 1 and SCANS = 1               <ul style="list-style-type: none"> <li>0000: AN0</li> <li>0001: AN0 and AN1</li> <li>0010: AN0 to AN2</li> <li>0011: AN0 to AN3</li> <li>0100: AN0 to AN4</li> <li>0101: AN0 to AN5</li> <li>0110: AN0 to AN6</li> <li>0111: AN0 to AN7</li> <li>1XXX: Setting prohibited</li> </ul> </li> </ul>

[Legend]

X: Don't care

Note: \* Only 0 can be written to this bit, to clear the flag.

### 15.3.3 A/D Control Register (ADCR)

ADCR enables A/D conversion to be started by an external trigger input.

Bit	7	6	5	4	3	2	1	0
Bit Name	TRGS1	TRGS0	SCANE	SCANS	CKS1	CKS0	—	—
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	TRGS1	0	R/W	Timer Trigger Select 1 and 0
6	TRGS0	0	R/W	These bits select enabling or disabling of the start of A/D conversion by a trigger signal. 00: A/D conversion start by external trigger is disabled 01: A/D conversion start by external trigger from TPU is enabled 10: Setting prohibited 11: A/D conversion start by the $\overline{\text{ADTRG}}$ pin is enabled*
5	SCANE	0	R/W	Scan Mode
4	SCANS	0	R/W	These bits select the A/D conversion operating mode. 0X: Single mode 10: Scan mode. A/D conversion is performed continuously for channels 1 to 4. 11: Scan mode. A/D conversion is performed continuously for channels 1 to 8.
3	CKS1	0	R/W	Clock Select 1 and 0
2	CKS0	0	R/W	These bits set the A/D conversion time. Set bits CKS1 and CKS0 only while A/D conversion is stopped (ADST = 0). 00: A/D conversion time = 530 states (max) 01: A/D conversion time = 266 states (max) 10: A/D conversion time = 134 states (max) 11: A/D conversion time = 68 states (max)
1, 0	—	All 0	R	Reserved These are read-only bits and cannot be modified.

[Legend]

X: Don't care

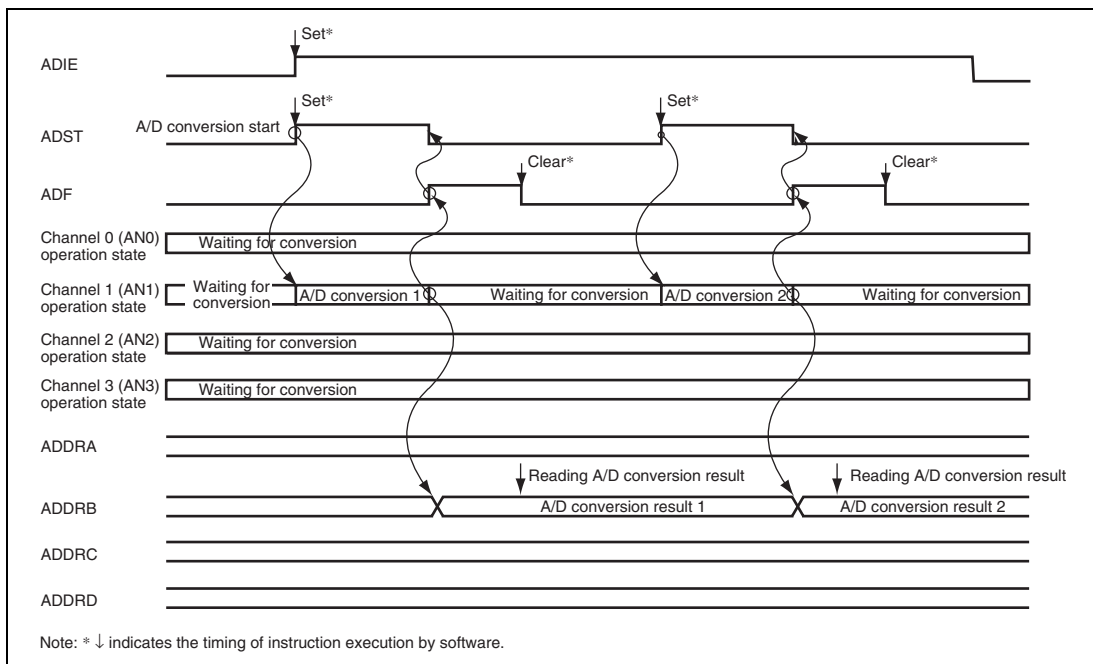

## 15.4 Operation

The A/D converter operates by successive approximation with 10-bit resolution. It has two operating modes: single mode and scan mode. When changing the operating mode or analog input channel, to prevent incorrect operation, first clear the ADST bit in ADCSR to 0 to halt A/D conversion. The ADST bit can be set to 1 at the same time as the operating mode or analog input channel is changed.

### 15.4.1 Single Mode

In single mode, A/D conversion is to be performed only once on the analog input of the specified single channel.

1. A/D conversion for the selected channel is started when the ADST bit in ADCSR is set to 1 by software or an external trigger input.
2. When A/D conversion is completed, the A/D conversion result is transferred to the corresponding A/D data register of the channel.
3. When A/D conversion is completed, the ADF bit in ADCSR is set to 1. If the ADIE bit is set to 1 at this time, an ADI interrupt request is generated.
4. The ADST bit remains set to 1 during A/D conversion, and is automatically cleared to 0 when A/D conversion ends. The A/D converter enters wait state. If the ADST bit is cleared to 0 during A/D conversion, A/D conversion stops and the A/D converter enters wait state.

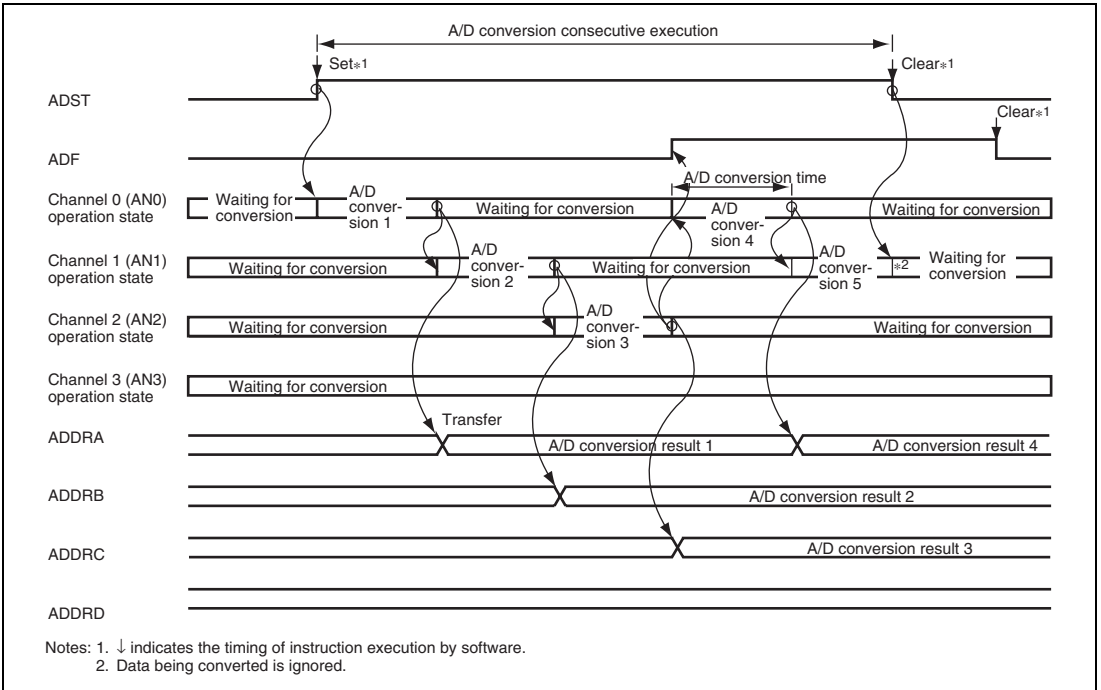

**Figure 15.3 Example of A/D Converter Operation (Single Mode, Channel 1 Selected)**

## 15.4.2 Scan Mode

In scan mode, A/D conversion is to be performed sequentially on the analog inputs of the specified channels up to four or eight channels.

1. When the ADST bit in ADCSR is set to 1 by software, TPU, or an external trigger input, A/D conversion starts on the first channel in the group. Consecutive A/D conversion on a maximum of four channels (SCANE and SCANS = B'10) or on a maximum of eight channels (SCANE and SCANS = B'11) can be selected. When consecutive A/D conversion is performed on four channels, A/D conversion starts on AN0 when CH3 and CH2 = B'00, on AN4 when CH3 and CH2 = B'01, on AN8 when CH3 and CH2 = B'10, and on AN12 when CH3 and CH2 = B'11. When consecutive A/D conversion is performed on eight channels, A/D conversion starts on AN0 when CH3 = B'0 and on AN8 when CH3 = B'1.
2. When A/D conversion for each channel is completed, the A/D conversion result is sequentially transferred to the corresponding ADDR of each channel.
3. When A/D conversion of all selected channels is completed, the ADF bit in ADCSR is set to 1. If the ADIE bit is set to 1 at this time, an ADI interrupt request is generated. A/D conversion of the first channel in the group starts again.

4. The ADST bit is not cleared automatically, and steps [2] to [3] are repeated as long as the ADST bit remains set to 1. When the ADST bit is cleared to 0, A/D conversion stops and the A/D converter enters wait state. If the ADST bit is later set to 1, A/D conversion starts again from the first channel in the group.

**Figure 15.4 Example of A/D Conversion  
(Scan Mode, Three Channels (AN0 to AN2) Selected)**

### 15.4.3 Input Sampling and A/D Conversion Time

The A/D converter has a built-in sample-and-hold circuit. The A/D converter samples the analog input when the A/D conversion start delay time ( $t_D$ ) passes after the ADST bit in ADCSR is set to 1, then starts A/D conversion. Figure 15.5 shows the A/D conversion timing. Table 15.3 indicates the A/D conversion time.

As indicated in figure 15.5, the A/D conversion time ( $t_{CONV}$ ) includes  $t_D$  and the input sampling time ( $t_{SPL}$ ). The length of  $t_D$  varies depending on the timing of the write access to ADCSR. The total conversion time therefore varies within the ranges indicated in table 15.3.

In scan mode, the values given in table 15.3 apply to the first conversion time. The values given in table 15.4 apply to the second and subsequent conversions. In either case, bits CKS1 and CKS0 in ADCR should be set so that the conversion time is within the ranges indicated by the A/D conversion characteristics.

**Figure 15.5 A/D Conversion Timing**

**Table 15.3 A/D Conversion Characteristics (Single Mode)**

Item	Symbol	CKS1 = 0						CKS1 = 1					
		CKS0 = 0			CKS0 = 1			CKS0 = 0			CKS0 = 1		
		Min.	Typ.	Max.	Min.	Typ.	Max.	Min.	Typ.	Max.	Min.	Typ.	Max.
A/D conversion start delay time	$t_D$	18	—	33	10	—	17	6	—	9	4	—	5
Input sampling time	$t_{SPL}$	—	127	—	—	63	—	—	31	—	—	15	—
A/D conversion time	$t_{CONV}$	515	—	530	259	—	266	131	—	134	67	—	68

Note: Values in the table are the number of states.

**Table 15.4 A/D Conversion Characteristics (Scan Mode)**

CKS1	CKS0	Conversion Time (Number of States)
0	0	512 (Fixed)
	1	256 (Fixed)
1	0	128 (Fixed)
	1	64 (Fixed)

#### 15.4.4 External Trigger Input Timing

A/D conversion can be externally triggered. When the TRGS1 and TRGS0 bits are set to B'11 in ADCR, an external trigger is input from the  $\overline{ADTRG}$  pin. A/D conversion starts when the ADST bit in ADCSR is set to 1 on the falling edge of the  $\overline{ADTRG}$  pin. Other operations, in both single and scan modes, are the same as when the ADST bit has been set to 1 by software. Figure 15.6 shows the timing.

**Figure 15.6 External Trigger Input Timing**

## 15.5 Interrupt Source

The A/D converter generates an A/D conversion end interrupt (ADI) at the end of A/D conversion. Setting the ADIE bit to 1 when the ADF bit in ADCSR is set to 1 after A/D conversion is completed enables ADI interrupt requests. The DMA controller (DMAC) can be activated by an ADI interrupt. Having the converted data read by the DMAC in response to an ADI interrupt enables continuous conversion to be achieved without imposing a load on software.

**Table 15.5 A/D Converter Interrupt Source**

Unit	Abbr.	Interrupt Source	Interrupt Flag	DMAC Activation
0	ADI0	A/D_0 conversion end	ADF	Possible
1	ADI1	A/D_1 conversion end	ADF	Possible

## 15.6 A/D Conversion Accuracy Definitions

This LSI's A/D conversion accuracy definitions are given below.

- Resolution  
The number of A/D converter digital output codes.
- Quantization error  
The deviation inherent in the A/D converter, given by 1/2 LSB (see figure 15.7).
- Offset error  
The deviation of the analog input voltage value from the ideal A/D conversion characteristic when the digital output changes from the minimum voltage value B'000000000 (H'000) to B'000000001 (H'001) (see figure 15.8).
- Full-scale error  
The deviation of the analog input voltage value from the ideal A/D conversion characteristic when the digital output changes from B'111111110 (H'3FE) to B'111111111 (H'3FF) (see figure 15.8).
- Nonlinearity error  
The error with respect to the ideal A/D conversion characteristic between the zero voltage and the full-scale voltage. Does not include the offset error, full-scale error, or quantization error (see figure 15.8).
- Absolute accuracy  
The deviation between the digital value and the analog input value. Includes the offset error, full-scale error, quantization error, and nonlinearity error.

**Figure 15.7 A/D Conversion Accuracy Definitions**

**Figure 15.8 A/D Conversion Accuracy Definitions**

## 15.7 Usage Notes

### 15.7.1 Module Stop Mode Setting

Operation of the A/D converter can be disabled or enabled using the module stop control register. The initial setting is for operation of the A/D converter to be halted. Register access is enabled by clearing module stop mode. For details, refer to section 19, Power-Down Modes.

### 15.7.2 Permissible Signal Source Impedance

This LSI's analog input is designed so that the conversion accuracy is guaranteed for an input signal for which the signal source impedance is  $5\text{ k}\Omega$  or less. This specification is provided to enable the A/D converter's sample-and-hold circuit input capacitance to be charged within the sampling time; if the sensor output impedance exceeds  $5\text{ k}\Omega$ , charging may be insufficient and it may not be possible to guarantee the A/D conversion accuracy. However, if a large capacitance is provided externally for conversion in single mode, the input load will essentially comprise only the internal input resistance of  $10\text{ k}\Omega$ , and the signal source impedance is ignored. However, since a low-pass filter effect is obtained in this case, it may not be possible to follow an analog signal with a large differential coefficient (e.g.,  $5\text{ mV}/\mu\text{s}$  or greater) (see figure 15.9). When converting a high-speed analog signal or conversion in scan mode, a low-impedance buffer should be inserted.

Figure 15.9 Example of Analog Input Circuit

### 15.7.3 Influences on Absolute Accuracy

Adding capacitance results in coupling with GND, and therefore noise in GND may adversely affect absolute accuracy. Be sure to make the connection to an electrically stable GND such as AVss.

Care is also required to insure that digital signals on the board do not interfere with filter circuits and filter circuits do not act as antennas.

### 15.7.4 Setting Range of Analog Power Supply and Other Pins

If the conditions shown below are not met, the reliability of the LSI may be adversely affected.

- Analog input voltage range

The voltage applied to analog input pin ANn during A/D conversion should be in the range  $AV_{SS} \leq V_{AN} \leq AV_{CC0}$  and  $AV_{SS} \leq V_{AN} \leq AV_{CC1}$ .

- Relation between AVcc0, AVcc1, AVss and Vcc, Vss

As the relationship between AVcc0, AVcc1, AVss and Vcc, Vss, set  $AV_{CC0} = V_{CC} \pm 0.3 \text{ V}$ ,  $AV_{CC1} = V_{CC} \pm 0.3 \text{ V}$ , and  $AV_{SS} = V_{SS}$ . If the A/D converter is not used, set  $AV_{CC0} = V_{CC}$ ,  $AV_{CC1} = V_{CC}$ , and  $AV_{SS} = V_{SS}$ .

### 15.7.5 Notes on Board Design

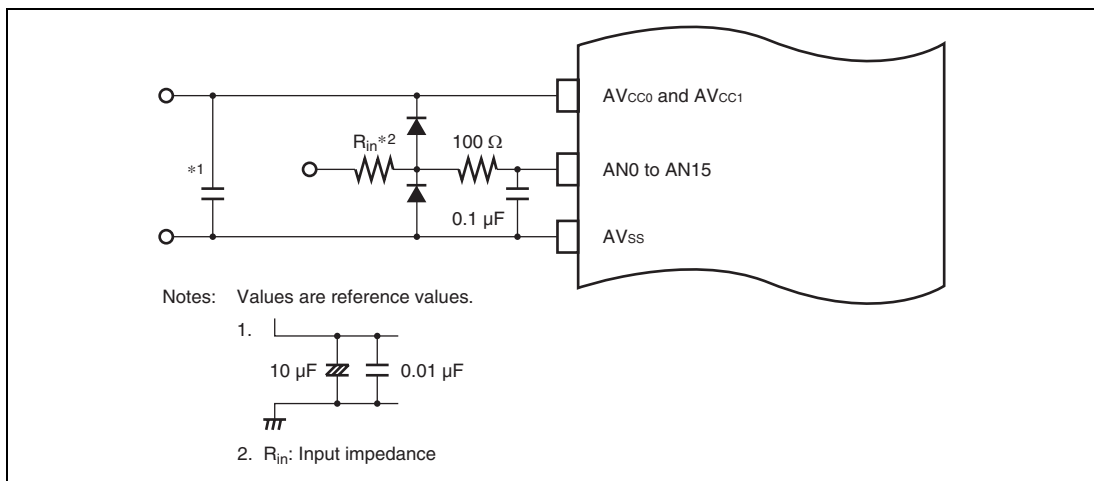

In board design, digital circuitry and analog circuitry should be as mutually isolated as possible, and layout in which digital circuit signal lines and analog circuit signal lines cross or are in close proximity should be avoided as far as possible. Failure to do so may result in incorrect operation of the analog circuitry due to inductance, adversely affecting A/D conversion values.

Digital circuitry must be isolated from the analog input pins (AN0 to AN15) and analog power supply (AVcc0 and AVcc1) by the analog ground (AVss). Also, the analog ground (AVss) should be connected at one point to a stable ground (Vss) on the board.

### 15.7.6 Notes on Noise Countermeasures

A protection circuit connected to prevent damage due to an abnormal voltage such as an excessive surge at the analog input pins (AN0 to AN15) should be connected between AVcc0, AVcc1 and AVss as shown in figure 15.10. Also, the bypass capacitors connected to AVcc0 and AVcc1 and the filter capacitor connected to pins AN0 to AN15 must be connected to AVss.

If a filter capacitor is connected, the input currents at pins AN0 to AN15 are averaged, and so an error may arise. Also, when A/D conversion is performed frequently, as in scan mode, if the current charged and discharged by the capacitance of the sample-and-hold circuit in the A/D converter exceeds the current input via the input impedance ( $R_{in}$ ), an error will arise in the analog input pin voltage. Careful consideration is therefore required when deciding the circuit constants.

**Figure 15.10 Example of Analog Input Protection Circuit**

**Table 15.6 Analog Pin Specifications**

Item	Min	Max	Unit
Analog input capacitance	—	20	pF
Permissible signal source impedance	—	5	kΩ

Note: Values are reference values.

**Figure 15.11 Analog Input Pin Equivalent Circuit**

### 15.7.7 A/D Input Hold Function in Software Standby Mode

When this LSI enters software standby mode with A/D conversion enabled, the A/D conversion are retained, and the analog current is equal to as during A/D conversion. If the analog power supply current needs to be reduced in software standby mode, clear the ADST, TRGS1, and TRGS0 bits all to 0 to disable A/D conversion.

## Section 16 RAM

This LSI has a 12-kbyte on-chip high-speed static RAM. The RAM is connected to the CPU by a 32-bit data bus, enabling 1-state read and 2-state write accesses by the CPU to all byte data, word data, and longword data.

The on-chip RAM can be enabled or disabled by means of the RAME bit in the system control register (SYSCR). For details on SYSCR, refer to section 3.2.2, System Control Register (SYSCR).

	<b>Product Classification</b>	<b>RAM Size</b>	<b>RAM Addresses</b>
Flash memory version	H8SX/1527R	12 kbytes	H'FF9000 to H'FFBFFF
	H8SX/1525R	12 kbytes	H'FF9000 to H'FFBFFF

## Section 17 Flash Memory (0.18- $\mu$ m F-ZTAT Version)

The flash memory has the following features. Figure 17.1 is a block diagram of the flash memory.

### 17.1 Features

- Size

Product Classification		ROM Size	ROM Address
H8SX/1527R	R5F61527R	256 kbytes	H'000000 to H'03FFFF (modes 1 to 3)
H8SX/1525R	R5F61525R		

- Two memory MATs

The start addresses of two memory spaces (memory MATs) are allocated to the same address. The mode setting in the initiation determines which memory MAT is initiated first. The memory MATs can be switched by using the bank-switching method after initiation.

- User MAT initiated at a power-on reset in user mode: 256 kbytes
- User boot MAT is initiated at a power-on reset in user boot mode: 10 kbytes

- Programming/erasing interface by the download of on-chip program

This LSI has a programming/erasing program. After downloading this program to the on-chip RAM, programming/erasing can be performed by setting the parameters. The user branch is also supported.

- User branch

The program processing is performed in 128-byte units. It consists of the program pulse application, verify read, and several other steps. Erasing is performed in one divided-block units and consists of several steps. The user processing routine can be executed between the steps, the setting for which is called the user branch addition.

- Programming/erasing time

Programming time: 3 ms (typ) for 128-byte simultaneous programming, 23.4  $\mu$ s per byte  
Erasing time: 1000 ms (typ) per 1 block (64 kbytes)

- Number of programming

The number of programming can be up to 100 times at the minimum. (1 to 100 times are guaranteed.)

- Three on-board programming modes

Boot mode: Using the on-chip SCI\_4, the user MAT and user boot MAT can be programmed/erased. In boot mode, the bit rate between the host and this LSI can be adjusted automatically.

User program mode: Using a desired interface, the user MAT can be programmed/erased.

User boot mode: Using a desired interface, the user boot program can be made and the user MAT can be programmed/erased.

- Off-board programming mode

Programmer mode: Using a PROM programmer, the user MAT and user boot MAT can be programmed/erased.

- Programming/erasing protection

Protection against programming/erasing of the flash memory can be set by hardware protection, software protection, or error protection.

- Flash memory emulation function using the on-chip RAM

Realtime emulation of the flash memory programming can be performed by overlaying parts of the flash memory (user MAT) area and the on-chip RAM.

**Figure 17.1 Block Diagram of Flash Memory**

## 17.2 Mode Transition Diagram

When the mode pins are set in the reset state and reset start is performed, this LSI enters each operating mode as shown in figure 17.2. Although the flash memory can be read in user mode, it cannot be programmed or erased. The flash memory can be programmed or erased in boot mode, user program mode, user boot mode, and programmer mode. The differences between boot mode, user program mode, user boot mode, and programmer mode are shown in table 17.1.

**Figure 17.2 Mode Transition of Flash Memory**

**Table 17.1 Differences between Boot Mode, User Program Mode, User Boot Mode, and Programmer Mode**

Item	Boot Mode	User Program Mode	User Boot Mode	Programmer Mode
Programming/erasing environment	On-board programming	On-board programming	On-board programming	Off-board programming
Programming/erasing enable MAT	<ul style="list-style-type: none"> <li>• User MAT</li> <li>• User boot MAT</li> </ul>	<ul style="list-style-type: none"> <li>• User MAT</li> </ul>	<ul style="list-style-type: none"> <li>• User MAT</li> </ul>	<ul style="list-style-type: none"> <li>• User MAT</li> <li>• User boot MAT</li> </ul>
Programming/erasing control	Command	Programming/erasing interface	Programming/erasing interface	Command
All erasure	O (Automatic)	O	O	O (Automatic)
Block division erasure	O* <sup>1</sup>	O	O	×
Program data transfer	From host via SCI	From desired device via RAM	From desired device via RAM	Via programmer
User branch function	×	O	O	×
RAM emulation	×	O	O	×
Reset initiation MAT	Embedded program storage area	User MAT	User boot MAT* <sup>2</sup>	—
Transition to user mode	Changing mode and reset	Completing Programming/erasure* <sup>3</sup>	Changing mode and reset	—

- Notes:
1. All-erasure is performed. After that, the specified block can be erased.
  2. First, the reset vector is fetched from the embedded program storage area. After the flash memory related registers are checked, the reset vector is fetched from the user boot MAT.
  3. In this LSI, the user programming mode is defined as the period from the timing when a program concerning programming and erasure is started to the timing when the program is completed. For details on a program concerning programming and erasure, see section 17.8.2, User Program Mode.

## 17.3 Memory MAT Configuration

The memory MATs of flash memory in this LSI consists of the 256-kbyte user MAT and 10-kbyte user boot MAT. The start addresses of the user MAT and user boot MAT are allocated to the same address. Therefore, when the program execution or data access is performed between the two memory MATs, the memory MATs must be switched by the flash MAT select register (FMATS).

The user MAT or user boot MAT can be read in all modes. However, the user boot MAT can be programmed or erased only in boot mode and programmer mode.

The size of the user MAT is different from that of the user boot MAT. Addresses which exceed the size of the 10-kbyte user boot MAT should not be accessed. If an attempt is made, data is read as an undefined value.

**Figure 17.3 Memory MAT Configuration**

## 17.4 Block Structure

Figure 17.4 shows the block structure of the 256-kbyte user MAT. The heavy-line frames indicate the erase blocks. The thin-line frames indicate the programming units and the values inside the frames stand for the addresses. The user MAT is divided into three 64-kbyte blocks, one 32-kbyte block, and eight 4-kbyte blocks. The user MAT can be erased in these divided block units. Programming is done in 128-byte units starting from where the lower address is H'00 or H'80. RAM emulation can be performed in the eight 4-kbyte blocks.

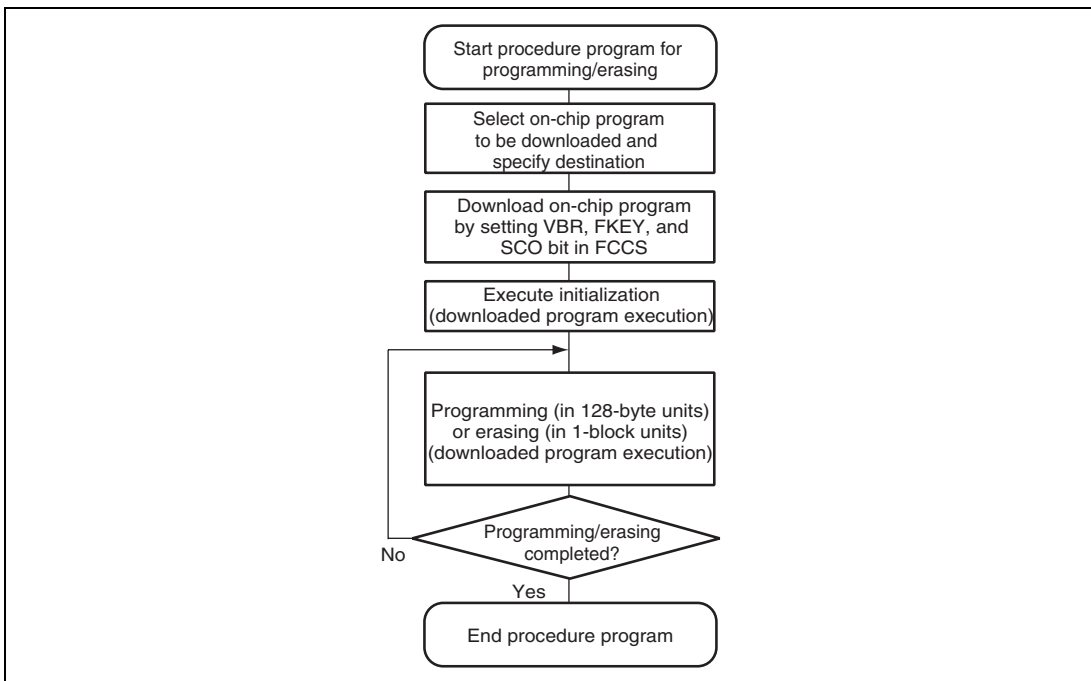

EB0 Erase unit: 4 kbytes	H'000000	H'000001	H'000002	←Programming unit: 128 bytes→	H'00007F
	H'000F80	H'000F81	H'000F82	-----	H'000FFF
EB1 Erase unit: 4 kbytes	H'001000	H'001001	H'001002	←Programming unit: 128 bytes→	H'00107F
	H'001F80	H'001F81	H'001F82	-----	H'001FFF
EB2 Erase unit: 4 kbytes	H'002000	H'002001	H'002002	←Programming unit: 128 bytes→	H'00207F
	H'002F80	H'002F81	H'002F82	-----	H'002FFF
EB3 Erase unit: 4 kbytes	H'003000	H'003001	H'003002	←Programming unit: 128 bytes→	H'00307F
	H'003F80	H'003F81	H'003F82	-----	H'003FFF
EB4 Erase unit: 4 kbytes	H'004000	H'004001	H'004002	←Programming unit: 128 bytes→	H'00407F

	H'02FF80	H'02FF81	H'02FF82	-----	H'02FFFF
EB11 Erase unit: 64 kbytes	H'030000	H'030001	H'030002	←Programming unit: 128 bytes→	H'03007F
	H'03FF80	H'03FF81	H'03FF82	-----	H'03FFFF

Figure 17.4 Block Structure of User MAT

## 17.5 Programming/Erasing Interface

Programming/erasing of the flash memory is done by downloading an on-chip programming/erasing program to the on-chip RAM and specifying the start address of the programming destination, the program data, and the erase block number using the programming/erasing interface registers and programming/erasing interface parameters.

The procedure program for user program mode and user boot mode is made by the user. Figure 17.5 shows the procedure for creating the procedure program. For details, see section 17.8.2, User Program Mode.

**Figure 17.5 Procedure for Creating Procedure Program**

### **(1) Selection of On-Chip Program to be Downloaded**

For programming/erasing, the FLSHE bit in the system control register (SYSCR) must be set to 1 to select user program mode. This LSI has programming/erasing programs which can be downloaded to the on-chip RAM. The on-chip program to be downloaded is selected by the programming/erasing interface registers. The start address of the on-chip RAM where an on-chip program is downloaded is specified by the flash transfer destination address register (FTDAR).

### **(2) Download of On-Chip Program**

The on-chip program is automatically downloaded by setting the flash key code register (FKEY) and the SCO bit in the flash code control/status register (FCCS) after initializing the vector base register (VBR). The memory MAT is replaced with the embedded program storage area during download. Since the memory MAT cannot be read during programming/erasing, the procedure program must be executed in a space other than the flash memory (for example, on-chip RAM). Since the download result is returned to the programming/erasing interface parameter, whether download is normally executed or not can be confirmed. The VBR contents can be changed after completion of download.

### **(3) Initialization of Programming/Erasing**

The operating frequency and user branch are set before execution of programming/erasing. The user branch destination must be in an area other than the on-chip flash memory and the area where the on-chip program is downloaded. These settings are made by using the programming/erasing interface parameters.

### **(4) Execution of Programming/Erasing**

For programming/erasing, the FLSHE bit in SYSCR must be set to 1 to make a transition to user program mode. The start address of the programming destination and the program data are specified in 128-byte units when programming. The block to be erased is specified with the erase block number in erase-block units when erasing. Specifications of the start address of the programming destination, program data, and erase block number are performed by the programming/erasing interface parameters, and the on-chip program is initiated. The on-chip program is executed by using the JSR or BSR instruction and executing the subroutine call of the specified address in the on-chip RAM. The execution result is returned to the programming/erasing interface parameter.

The area to be programmed must be erased in advance when programming flash memory. All interrupts are disabled during programming/erasing.

### (5) When Programming/Erasing is Executed Consecutively

When processing does not end by 128-byte programming or 1-block erasure, consecutive programming/erasing can be realized by updating the start address of the programming destination and program data, or the erase block number. Since the downloaded on-chip program is left in the on-chip RAM even after programming/erasing completes, download and initialization are not required when the same processing is executed consecutively.

## 17.6 Input/Output Pins

The flash memory is controlled through the input/output pins shown in table 17.2.

**Table 17.2 Pin Configuration**

<b>Pin Name</b>	<b>I/O</b>	<b>Function</b>
RES	Input	Reset
MD1 and MD0	Input	Set operating mode of this LSI
TxD4	Output	Serial transmit data output (used in boot mode)
RxD4	Input	Serial receive data input (used in boot mode)

## 17.7 Register Descriptions

The flash memory has the following registers. To access these registers, the FLSHE bit in the system control register (SYSCR) must be set to 1. For details on SYSCR, see section 3.2.2, System Control Register (SYSCR).

### Programming/Erasing Interface Registers:

- Flash code control/status register (FCCS)
- Flash program code select register (FPCS)
- Flash erase code select register (FECS)
- Flash key code register (FKEY)
- Flash MAT select register (FMATS)
- Flash transfer destination address register (FTDAR)

### Programming/Erasing Interface Parameters:

- Download pass and fail result parameter (DPFR)
- Flash pass and fail result parameter (FPFR)
- Flash program/erase frequency parameter (FPEFEQ)
- Flash user branch set parameter (FUBRA)
- Flash multipurpose address area parameter (FMPAR)
- Flash multipurpose data destination area parameter (FMPDR)
- Flash erase block select parameter (FEBS)
  
- RAM emulation register (RAMER)

There are several operating modes for accessing the flash memory. Respective operating modes, registers, and parameters are assigned to the user MAT and user boot MAT. The correspondence between operating modes and registers/parameters for use is shown in table 17.3.

**Table 17.3 Registers/Parameters and Target Modes**

Register/Parameter		Down- load	Initiali- zation	Program- ming	Erase	Read	RAM Emulation
Programming/ erasing interface registers	FCCS	O	—	—	—	—	—
	FPCS	O	—	—	—	—	—
	FECS	O	—	—	—	—	—
	FKEY	O	—	O	O	—	—
	FMATS	—	—	O* <sup>1</sup>	O* <sup>1</sup>	O* <sup>2</sup>	—
	FTDAR	O	—	—	—	—	—
Programming/ erasing interface parameters	DPFR	O	—	—	—	—	—
	FPFR	—	O	O	O	—	—
	FPEFEQ	—	O	—	—	—	—
	FUBRA	—	O	—	—	—	—
	FMPAR	—	—	O	—	—	—
	FMPDR	—	—	O	—	—	—
	FEBS	—	—	—	O	—	—
RAM emulation	RAMER	—	—	—	—	—	O

Notes: 1. The setting is required when programming or erasing the user MAT in user boot mode.  
2. The setting may be required according to the combination of initiation mode and read target memory MAT.

### 17.7.1 Programming/Erasing Interface Registers

The programming/erasing interface registers are 8-bit registers that can be accessed only in bytes. These registers are initialized by a power-on reset.

#### (1) Flash Code Control/Status Register (FCCS)

FCCS monitors errors during programming/erasing the flash memory and requests the on-chip program to be downloaded to the on-chip RAM.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	—	FLER	—	—	—	SCO
Initial Value	1	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	(R)/W

Bit	Bit Name	Initial Value	R/W	Description
7	—	1	R	Reserved
6	—	0	R	These are read-only bits and cannot be modified.
5	—	0	R	
4	FLER	0	R	<p>Flash Memory Error</p> <p>Indicates that an error has occurred during programming or erasing the flash memory. When this bit is set to 1, the flash memory enters the error protection state. When this bit is set to 1, high voltage is applied to the internal flash memory. To reduce the damage to the flash memory, the reset must be released after the reset input period (period of <math>\overline{\text{RES}} = 0</math>) of at least 100 <math>\mu</math>s.</p> <p>0: Flash memory operates normally (Error protection is invalid)</p> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>At a power-on reset</li> </ul> <p>1: An error occurs during programming/erasing flash memory (Error protection is valid)</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>When an interrupt, such as NMI, occurs during programming/erasing.</li> <li>When the flash memory is read during programming/erasing (including a vector read and an instruction fetch).</li> <li>When the SLEEP instruction is executed during programming/erasing (including software standby mode).</li> <li>When a bus master other than the CPU, such as the DMAC, obtains bus mastership during programming/erasing.</li> </ul>
3 to 1	—	All 0	R	<p>Reserved</p> <p>These are read-only bits and cannot be modified.</p>

Bit	Bit Name	Initial Value	R/W	Description
0	SCO	0	(R)/W*	<p>Source Program Copy Operation</p> <p>Requests the on-chip programming/erasing program to be downloaded to the on-chip RAM. When this bit is set to 1, the on-chip program which is selected by FPCS or FECS is automatically downloaded in the on-chip RAM area specified by FTDAR.</p> <p>In order to set this bit to 1, the RAM emulation mode must be canceled, H'A5 must be written to FKEY, and this operation must be executed in the on-chip RAM. Dummy read of FCCS must be executed twice immediately after setting this bit to 1. All interrupts must be disabled during download. This bit is cleared to 0 when download is completed.</p> <p>During program download initiated with this bit, particular processing which accompanies bank-switching of the program storage area is executed. Before a download request, initialize the VBR contents to H'00000000. After download is completed, the VBR contents can be changed.</p> <p>0: Download of the programming/erasing program is not requested.</p> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>• When download is completed</li> </ul> <p>1: Download of the programming/erasing program is requested.</p> <p>[Setting conditions] (When all of the following conditions are satisfied)</p> <ul style="list-style-type: none"> <li>• Not in RAM emulation mode (the RAMS bit in RAMER is cleared to 0)</li> <li>• H'A5 is written to FKEY</li> <li>• Setting of this bit is executed in the on-chip RAM</li> </ul>

Note: \* This is a write-only bit. This bit is always read as 0.

**(2) Flash Program Code Select Register (FPCS)**

FPCS selects the programming program to be downloaded.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	—	—	—	—	—	PPVS
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved These are read-only bits and cannot be modified.
0	PPVS	0	R/W	Program Pulse Verify Selects the programming program to be downloaded. 0: Programming program is not selected. [Clearing condition] When transfer is completed. 1: Programming program is selected.

**(3) Flash Erase Code Select Register (FECS)**

FECS selects the erasing program to be downloaded.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	—	—	—	—	—	EPVB
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved These are read-only bits and cannot be modified.
0	EPVB	0	R/W	Erase Pulse Verify Block Selects the erasing program to be downloaded. 0: Erasing program is not selected. [Clearing condition] When transfer is completed. 1: Erasing program is selected.

**(4) Flash Key Code Register (FKEY)**

FKEY is a register for software protection that enables to download the on-chip program and perform programming/erasing of the flash memory.

Bit	7	6	5	4	3	2	1	0
Bit Name	K7	K6	K5	K4	K3	K2	K1	K0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	K7	0	R/W	Key Code
6	K6	0	R/W	When H'A5 is written to FKEY, writing to the SCO bit in FCCS is enabled. When a value other than H'A5 is written, the SCO bit cannot be set to 1. Therefore, the on-chip program cannot be downloaded to the on-chip RAM.
5	K5	0	R/W	
4	K4	0	R/W	
3	K3	0	R/W	
2	K2	0	R/W	Only when H'5A is written can programming/erasing of the flash memory be executed. When a value other than H'5A is written, even if the programming/erasing program is executed, programming/erasing cannot be performed.
1	K1	0	R/W	
0	K0	0	R/W	

H'A5: Writing to the SCO bit is enabled. (The SCO bit cannot be set to 1 when FKEY is a value other than H'A5.)

H'5A: Programming/erasing of the flash memory is enabled. (When FKEY is a value other than H'5A, the software protection state is entered.)

H'00: Initial value

**(5) Flash MAT Select Register (FMATS)**

FMATS selects the user MAT or user boot MAT. Writing to FMATS should be done when a program in the on-chip RAM is being executed.

Bit	7	6	5	4	3	2	1	0
Bit Name	MS7	MS6	MS5	MS4	MS3	MS2	MS1	MS0
Initial Value	0/1*	0	0/1*	0	0/1*	0	0/1*	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: \* This bit is set to 1 in user boot mode, otherwise cleared to 0.

Bit	Bit Name	Initial Value	R/W	Description
7	MS7	0/1*	R/W	MAT Select
6	MS6	0	R/W	The memory MATs can be switched by writing a value to FMATS.
5	MS5	0/1*	R/W	
4	MS4	0	R/W	When H'AA is written to FMATS, the user boot MAT is selected. When a value other than H'AA is written, the user MAT is selected. Switch the MATs following the memory MAT switching procedure in section 17.11,
3	MS3	0/1*	R/W	Switching between User MAT and User Boot MAT. The user boot MAT cannot be selected by FMATS in user programming mode. The user boot MAT can be selected in boot mode or programmer mode.
2	MS2	0	R/W	
1	MS1	0/1*	R/W	
0	MS0	0	R/W	

H'AA: The user boot MAT is selected. (The user MAT is selected when FMATS is a value other than H'AA.)  
(Initial value when initiated in user boot mode.)

H'00: The user MAT is selected.  
(Initial value when initiated in a mode except for user boot mode.)

Note: \* This bit is set to 1 in user boot mode, otherwise cleared to 0.

**(6) Flash Transfer Destination Address Register (FTDAR)**

FTDAR specifies the start address of the on-chip RAM at which to download an on-chip program. FTDAR must be set before setting the SCO bit in FCCS to 1.

Bit	7	6	5	4	3	2	1	0
Bit Name	TDER	TDA6	TDA5	TDA4	TDA3	TDA2	TDA1	TDA0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	TDER	0	R/W	<p>Transfer Destination Address Setting Error</p> <p>This bit is set to 1 when an error has occurred in setting the start address specified by bits TDA6 to TDA0.</p> <p>A start address error is determined by whether the value set in bits TDA6 to TDA0 is within the range of H'00 to H'02 when download is executed by setting the SCO bit in FCCS to 1. Make sure that this bit is cleared to 0 before setting the SCO bit to 1 and the value specified by bits TDA6 to TDA0 should be within the range of H'00 to H'02.</p> <p>0: The value specified by bits TDA6 to TDA0 is within the range.</p> <p>1: The value specified by bits TDA6 to TDA0 is between H'03 and H'FF and download has stopped.</p>
6	TDA6	0	R/W	Transfer Destination Address
5	TDA5	0	R/W	Specifies the on-chip RAM start address of the download destination. A value between H'00 and H'02, and up to 4 kbytes can be specified as the start address of the on-chip RAM.
4	TDA4	0	R/W	
3	TDA3	0	R/W	
2	TDA2	0	R/W	H'00: H'FF9000 is specified as the start address.
1	TDA1	0	R/W	H'01: H'FFA000 is specified as the start address.
0	TDA0	0	R/W	H'02: H'FFB000 is specified as the start address.
				H'03 to H'7F: Setting prohibited. (Specifying a value from H'03 to H'7F sets the TDER bit to 1 and stops download of the on-chip program.)

## 17.7.2 Programming/Erasing Interface Parameters

The programming/erasing interface parameters specify the operating frequency, user branch destination address, storage place for program data, start address of programming destination, and erase block number, and exchanges the execution result. These parameters use the general registers of the CPU (ER0 and ER1) or the on-chip RAM area. The initial values of programming/erasing interface parameters are undefined at a power-on reset or a transition to software standby mode.

Since registers of the CPU except for R0 are saved in the stack area during download of an on-chip program, initialization, programming, or erasing, allocate the stack area before performing these operations (the maximum stack size is 128 bytes). The return value of the processing result is written in R0. The programming/erasing interface parameters are used in download control, initialization before programming or erasing, programming, and erasing. Table 17.4 shows the usable parameters and target modes. The meaning of the bits in the flash pass and fail result parameter (FPFR) varies in initialization, programming, and erasure.

**Table 17.4 Parameters and Target Modes**

Parameter	Download	Initialization	Programming	Erasure	R/W	Initial Value	Allocation
DPFR	○	—	—	—	R/W	Undefined	On-chip RAM*
FPFR	—	○	○	○	R/W	Undefined	R0L of CPU
FPEFEQ	—	○	—	—	R/W	Undefined	ER0 of CPU
FUBRA	—	○	—	—	R/W	Undefined	ER0 of CPU
FMPAR	—	—	○	—	R/W	Undefined	ER1 of CPU
FMPDR	—	—	○	—	R/W	Undefined	ER0 of CPU
FEBS	—	—	—	○	R/W	Undefined	ER0 of CPU

Note: \* A single byte of the start address of the on-chip RAM specified by FTDAR

**Download Control:** The on-chip program is automatically downloaded by setting the SCO bit in FCCS to 1. The on-chip RAM area to download the on-chip program is the 4-kbyte area starting from the start address specified by FTDAR. Download is set by the programming/erasing interface registers, and the download pass and fail result parameter (DPFR) indicates the return value.

**Initialization before Programming/Erasing:** The on-chip program includes the initialization program. A pulse with the specified period must be applied when programming or erasing. The specified pulse width is made by the method in which wait loop is configured by the CPU instruction. Accordingly, the operating frequency of the CPU must be set. Since the user branch function is supported, the user branch destination address must be set. The initial program is set as a parameter of the programming/erasing program which has been downloaded to perform these settings.

**Programming:** When the flash memory is programmed, the start address of the programming destination on the user MAT and the program data must be passed to the programming program.

The start address of the programming destination on the user MAT must be stored in general register ER1. This parameter is called the flash multipurpose address area parameter (FMPAR).

The program data is always in 128-byte units. When the program data does not satisfy 128 bytes, 128-byte program data is prepared by filling the dummy code (H'FF). The boundary of the start address of the programming destination on the user MAT is aligned at an address where the lower eight bits (A7 to A0) are H'00 or H'80.

The program data for the user MAT must be prepared in consecutive areas. The program data must be in a consecutive space which can be accessed using the MOV.B instruction of the CPU and is not in the flash memory space.

The start address of the area that stores the data to be written in the user MAT must be set in general register ER0. This parameter is called the flash multipurpose data destination area parameter (FMPDR).

For details on the programming procedure, see section 17.8.2, User Program Mode.

**Erasure:** When the flash memory is erased, the erase block number on the user MAT must be passed to the erasing program which is downloaded.

The erase block number on the user MAT must be set in general register ER0. This parameter is called the flash erase block select parameter (FEBS).

One block is selected from the block numbers of 0 to 11 as the erase block number.

For details on the erasing procedure, see section 17.8.2, User Program Mode.

**(1) Download Pass and Fail Result Parameter (DPFR: Single Byte of Start Address in On-Chip RAM Specified by FTDAR)**

DPFR indicates the return value of the download result. The DPFR value is used to determine the download result.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	—	—	—	SS	FK	SF

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	—	—	Unused These bits return 0.
2	SS	—	R/W	Source Select Error Detect Only one type can be specified for the on-chip program which can be downloaded. When the program to be downloaded is not selected, more than two types of programs are selected, or a program which is not mapped is selected, an error occurs. 0: Download program selection is normal 1: Download program selection is abnormal
1	FK	—	R/W	Flash Key Register Error Detect Checks the FKEY value (H'A5) and returns the result. 0: FKEY setting is normal (H'A5) 1: FKEY setting is abnormal (value other than H'A5)
0	SF	—	R/W	Success/Fail Returns the download result. Reads back the program downloaded to the on-chip RAM and determines whether it has been transferred to the on-chip RAM. 0: Download of the program has ended normally (no error) 1: Download of the program has ended abnormally (error occurs)

**(2) Flash Pass and Fail Parameter (FPFR: General Register R0L of CPU)**

FPFR indicates the return values of the initialization, programming, and erasure results. The meaning of the bits in FPFR varies depending on the processing.

**(a) Initialization before programming/erasing**

FPFR indicates the return value of the initialization result.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	—	—	—	BR	FQ	SF

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	—	—	Unused These bits return 0.
2	BR	—	R/W	User Branch Error Detect Returns the check result whether the specified user branch destination address is the area other than the storage area of the programming/erasing program which has been downloaded. 0: User branch address setting is normal 1: User branch address setting is abnormal
1	FQ	—	R/W	Frequency Error Detect Compares the specified CPU operating frequency with the operating frequencies supported by this LSI, and returns the result. 0: Setting of operating frequency is normal 1: Setting of operating frequency is abnormal
0	SF	—	R/W	Success/Fail Returns the initialization result. 0: Initialization has ended normally (no error) 1: Initialization has ended abnormally (error occurs)

**(b) Programming**

PPFR indicates the return value of the programming result.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	MD	EE	FK	—	WD	WA	SF

Bit	Bit Name	Initial Value	R/W	Description
7	—	—	—	Unused Returns 0.
6	MD	—	R/W	<p>Programming Mode Related Setting Error Detect</p> <p>Detects the error protection state and returns the result. When the error protection state is entered, this bit is set to 1. Whether the error protection state is entered or not can be confirmed with the FLER bit in FCCS. For conditions to enter the error protection state, see section 17.9.3, Error Protection.</p> <p>0: Normal operation (FLER = 0) 1: Error protection state, and programming cannot be performed (FLER = 1)</p>
5	EE	—	R/W	<p>Programming Execution Error Detect</p> <p>Writes 1 to this bit when the specified data could not be written because the user MAT was not erased. If this bit is set to 1, there is a high possibility that the user MAT has been written to partially. In this case, after removing the error factor, erase the user MAT. If FMATS is set to H'AA and the user boot MAT is selected, an error occurs when programming is performed. In this case, both the user MAT and user boot MAT have not been written to. Programming the user boot MAT should be performed in boot mode or programmer mode.</p> <p>0: Programming has ended normally 1: Programming has ended abnormally (programming result is not guaranteed)</p>
4	FK	—	R/W	<p>Flash Key Register Error Detect</p> <p>Checks the FKEY value (H'5A) before programming starts, and returns the result.</p> <p>0: FKEY setting is normal (H'5A) 1: FKEY setting is abnormal (value other than H'5A)</p>

Bit	Bit Name	Initial Value	R/W	Description
3	—	—	—	Unused Returns 0.
2	WD	—	R/W	Write Data Address Detect When an address not in the flash memory area is specified as the start address of the storage destination for the program data, an error occurs. 0: Setting of the start address of the storage destination for the program data is normal 1: Setting of the start address of the storage destination for the program data is abnormal
1	WA	—	R/W	Write Address Error Detect When the following items are specified as the start address of the programming destination, an error occurs. <ul style="list-style-type: none"> <li>• An area other than flash memory</li> <li>• The specified address is not aligned with the 128-byte boundary (lower eight bits of the address are other than H'00 and H'80)</li> </ul> 0: Setting of the start address of the programming destination is normal 1: Setting of the start address of the programming destination is abnormal
0	SF	—	R/W	Success/Fail Returns the programming result. 0: Programming has ended normally (no error) 1: Programming has ended abnormally (error occurs)

**(c) Erasure**

FPFR indicates the return value of the erasure result.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	MD	EE	FK	EB	—	—	SF

Bit	Bit Name	Initial Value	R/W	Description
7	—	—	—	Unused Returns 0.
6	MD	—	R/W	Erasure Mode Related Setting Error Detect Detects the error protection state and returns the result. When the error protection state is entered, this bit is set to 1. Whether the error protection state is entered or not can be confirmed with the FLER bit in FCCS. For conditions to enter the error protection state, see section 17.9.3, Error Protection. 0: Normal operation (FLER = 0) 1: Error protection state, and programming cannot be performed (FLER = 1)
5	EE	—	R/W	Erasure Execution Error Detect Returns 1 when the user MAT could not be erased or when the flash memory related register settings are partially changed. If this bit is set to 1, there is a high possibility that the user MAT has been erased partially. In this case, after removing the error factor, erase the user MAT. If FMATS is set to H'AA and the user boot MAT is selected, an error occurs when erasure is performed. In this case, both the user MAT and user boot MAT have not been erased. Erasing of the user boot MAT should be performed in boot mode or programmer mode. 0: Erasure has ended normally 1: Erasure has ended abnormally

Bit	Bit Name	Initial Value	R/W	Description
4	FK	—	R/W	Flash Key Register Error Detect Checks the FKEY value (H'5A) before erasure starts, and returns the result. 0: FKEY setting is normal (H'5A) 1: FKEY setting is abnormal (value other than H'5A)
3	EB	—	R/W	Erase Block Select Error Detect Checks whether the specified erase block number is in the block range of the user MAT, and returns the result. 0: Setting of erase block number is normal 1: Setting of erase block number is abnormal
2, 1	—	—	—	Unused These bits return 0.
0	SF	—	R/W	Success/Fail Indicates the erasure result. 0: Erasure has ended normally (no error) 1: Erasure has ended abnormally (error occurs)

**(3) Flash Program/Erase Frequency Parameter (FPEFEQ: General Register ER0 of CPU)**

FPEFEQ sets the operating frequency of the CPU. The CPU operating frequency available in this LSI ranges from 8 to 48 MHz.

Bit	31	30	29	28	27	26	25	24
Bit Name	—	—	—	—	—	—	—	—
Bit	23	22	21	20	19	18	17	16
Bit Name	—	—	—	—	—	—	—	—
Bit	15	14	13	12	11	10	9	8
Bit Name	F15	F14	F13	F12	F11	F10	F9	F8
Bit	7	6	5	4	3	2	1	0
Bit Name	F7	F6	F5	F4	F3	F2	F1	F0

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	—	—	Unused These bits should be cleared to 0.
15 to 0	F15 to F0	—	R/W	Frequency Set These bits set the operating frequency of the CPU. When the PLL multiplication function is used, set the multiplied frequency. The setting value must be calculated as follows: <ol style="list-style-type: none"> <li>1. The operating frequency shown in MHz units must be rounded in a number of three decimal places and be shown in a number of two decimal places.</li> <li>2. The value multiplied by 100 is converted to the binary digit and is written to FPEFEQ (general register ER0).</li> </ol> For example, when the operating frequency of the CPU is 33.000 MHz, the value is as follows: <ol style="list-style-type: none"> <li>1. The number of three decimal places of 33.000 is rounded.</li> <li>2. The formula of <math>33.00 \times 100 = 3300</math> is converted to the binary digit and B'0000 1100 1110 0100 (H'0CE4) is set to ER0.</li> </ol>

**(4) Flash Multipurpose Address Area Parameter (FMPAR: General Register ER1 of CPU)**

FMPAR stores the start address of the programming destination on the user MAT.

When an address in an area other than the flash memory is set, or the start address of the programming destination is not aligned with the 128-byte boundary, an error occurs. The error occurrence is indicated by the WA bit in FPFR.

Bit	31	30	29	28	27	26	25	24
Bit Name	MOA31	MOA30	MOA29	MOA28	MOA27	MOA26	MOA25	MOA24
Bit	23	22	21	20	19	18	17	16
Bit Name	MOA23	MOA22	MOA21	MOA20	MOA19	MOA18	MOA17	MOA16
Bit	15	14	13	12	11	10	9	8
Bit Name	MOA15	MOA14	MOA13	MOA12	MOA11	MOA10	MOA9	MOA8
Bit	7	6	5	4	3	2	1	0
Bit Name	MOA7	MOA6	MOA5	MOA4	MOA3	MOA2	MOA1	MOA0

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MOA31 to MOA0	—	R/W	These bits store the start address of the programming destination on the user MAT. Consecutive 128-byte programming is executed starting from the specified start address of the user MAT. Therefore, the specified start address of the programming destination becomes a 128-byte boundary, and MOA6 to MOA0 are always cleared to 0.

### (5) Flash Multipurpose Data Destination Parameter (FMPDR: General Register ER0 of CPU)

FMPDR stores the start address in the area which stores the data to be programmed in the user MAT.

When the storage destination for the program data is in flash memory, an error occurs. The error occurrence is indicated by the WD bit in FPCR.

Bit	31	30	29	28	27	26	25	24
Bit Name	MOD31	MOD30	MOD29	MOD28	MOD27	MOD26	MOD25	MOD24
Bit	23	22	21	20	19	18	17	16
Bit Name	MOD23	MOD22	MOD21	MOD20	MOD19	MOD18	MOD17	MOD16
Bit	15	14	13	12	11	10	9	8
Bit Name	MOD15	MOD14	MOD13	MOD12	MOD11	MOD10	MOD9	MOD8
Bit	7	6	5	4	3	2	1	0
Bit Name	MOD7	MOD6	MOD5	MOD4	MOD3	MOD2	MOD1	MOD0

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MOD31 to MOD0	—	R/W	These bits store the start address of the area which stores the program data for the user MAT. Consecutive 128-byte data is programmed to the user MAT starting from the specified start address.

**(6) Flash Erase Block Select Parameter (FEBS: General Register ER0 of CPU)**

FEBS specifies the erase block number. Settable values for the erase block numbers range from 0 to 11 (H'00000000 to H'0000000B). A value of 0 corresponds to block EB0 and a value of 11 corresponds to block EB11. An error occurs when a value outside the range from 0 to 11 is set.

Bit	31	30	29	28	27	26	25	24
Bit Name								
Initial Value	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	23	22	21	20	19	18	17	16
Bit Name								
Initial Value	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8
Bit Name								
Initial Value	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	7	6	5	4	3	2	1	0
Bit Name								
Initial Value	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

**(7) Flash User Branch Address Set Parameter (FUBRA: General Register ER0 of CPU)**

This parameter sets the user branch destination address. The user program which has been set can be executed in specified processing units when programming and erasing.

When the user branch is not required, address 0 (H'00000000) must be set.

The user branch destination must be an area other than the on-chip flash memory or an area other than the RAM area in which on-chip program has been transferred.

Note that the CPU must not branch to an area without the execution code and get out of control. The on-chip program download area and stack area must not be overwritten. If CPU runaway occurs or the download area or stack area is overwritten, the value of flash memory cannot be guaranteed.

The download of the on-chip program, initialization, initiation of the programming/erasing program must not be executed in the processing of the user branch destination. Programming or erasing cannot be guaranteed when returning from the user branch destination. The program data which has already been prepared must not be programmed.

Store general registers ER2 to ER7. General registers ER0 and ER1 are available without storing them.

Moreover, the programming/erasing interface registers must not be written to or RAM emulation mode must not be entered in the processing of the user branch destination.

After the processing of the user branch has ended, the programming/erasing program must be returned to by using the RTS instruction.

Bit	31	30	29	28	27	26	25	24
Bit Name	UA31	UA30	UA29	UA28	UA27	UA26	UA25	UA24

Bit	23	22	21	20	19	18	17	16
Bit Name	UA23	UA22	UA21	UA20	UA19	UA18	UA17	UA16

Bit	15	14	13	12	11	10	9	8
Bit Name	UA15	UA14	UA13	UA12	UA11	UA10	UA9	UA8

Bit	7	6	5	4	3	2	1	0
Bit Name	UA7	UA6	UA5	UA4	UA3	UA2	UA1	UA0

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	UA31 to UA0	—	R/W	Sets the start address in the user branch destination.

### 17.7.3 RAM Emulation Register (RAMER)

RAMER specifies the user MAT area overlaid with part of the on-chip RAM (H'FFFA000 to H'FFFAFFF) when performing emulation of programming the user MAT. RAMER should be set in user mode or user program mode. To ensure dependable emulation, the memory MAT to be emulated must not be accessed immediately after changing the RAMER contents. When accessed at such a timing, correct operation is not guaranteed.

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	—	—	RAMS	RAM2	RAM1	RAM0
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	0	R	Reserved These are read-only bits and cannot be modified.
3	RAMS	0	R/W	RAM Select Selects the function which emulates the flash memory using the on-chip RAM. 0: Disables RAM emulation function 1: Enables RAM emulation function (all blocks of the user MAT are protected against programming and erasing)
2	RAM2	0	R/W	Flash Memory Area Select
1	RAM1	0	R/W	These bits select the user MAT area overlaid with the on-chip RAM when RAMS = 1. The following areas correspond to the 4-kbyte erase blocks.
0	RAM0	0	R/W	
				000: H'000000 to H'000FFF (EB0) 001: H'001000 to H'001FFF (EB1) 010: H'002000 to H'002FFF (EB2) 011: H'003000 to H'003FFF (EB3) 100: H'004000 to H'004FFF (EB4) 101: H'005000 to H'005FFF (EB5) 110: H'006000 to H'006FFF (EB6) 111: H'007000 to H'007FFF (EB7)

## 17.8 On-Board Programming Mode

When the mode pins (MD0, MD1, and MD2) are set to on-board programming mode and the reset start is executed, a transition is made to on-board programming mode in which the on-chip flash memory can be programmed/erased. On-board programming mode has three operating modes: boot mode, user boot mode, and user program mode.

Table 17.5 shows the pin setting for each operating mode. For details on the state transition of each operating mode for flash memory, see figure 17.2.

**Table 17.5 On-Board Programming Mode Setting**

Mode Setting	MD1	MD0
User boot mode	0	1
Boot mode	1	0
User program mode	1	1

### 17.8.1 Boot Mode

Boot mode executes programming/erasing of the user MAT or user boot MAT by means of the control command and program data transmitted from the externally connected host via the on-chip SCI\_4.

In boot mode, the tool for transmitting the control command and program data, and the program data must be prepared in the host. The serial communication mode is set to asynchronous mode. The system configuration in boot mode is shown in figure 17.6. Interrupts are ignored in boot mode. Configure the user system so that interrupts do not occur.

**Figure 17.6 System Configuration in Boot Mode**

## (1) Serial Interface Setting by Host

The SCI\_4 is set to asynchronous mode, and the serial transmit/receive format is set to 8-bit data, one stop bit, and no parity.

When a transition to boot mode is made, the boot program embedded in this LSI is initiated.

When the boot program is initiated, this LSI measures the low period of asynchronous serial communication data (H'00) transmitted consecutively by the host, calculates the bit rate, and adjusts the bit rate of the SCI\_4 to match that of the host.

When bit rate adjustment is completed, this LSI transmits 1 byte of H'00 to the host as the bit adjustment end sign. When the host receives this bit adjustment end sign normally, it transmits 1 byte of H'55 to this LSI. When reception is not executed normally, initiate boot mode again. The bit rate may not be adjusted within the allowable range depending on the combination of the bit rate of the host and the system clock frequency of this LSI. Therefore, the transfer bit rate of the host and the system clock frequency of this LSI must be as shown in table 17.6.

**Figure 17.7 Automatic-Bit-Rate Adjustment Operation**

**Table 17.6 System Clock Frequency for Automatic-Bit-Rate Adjustment**

Bit Rate of Host	System Clock Frequency of This LSI	External Clock Frequency
9,600 bps	8 to 18 MHz	4 to 9 MHz
19,200 bps	16 to 18 MHz	8 to 9 MHz

## (2) State Transition Diagram

The state transition after boot mode is initiated is shown in figure 17.8.

**Figure 17.8 Boot Mode State Transition Diagram**

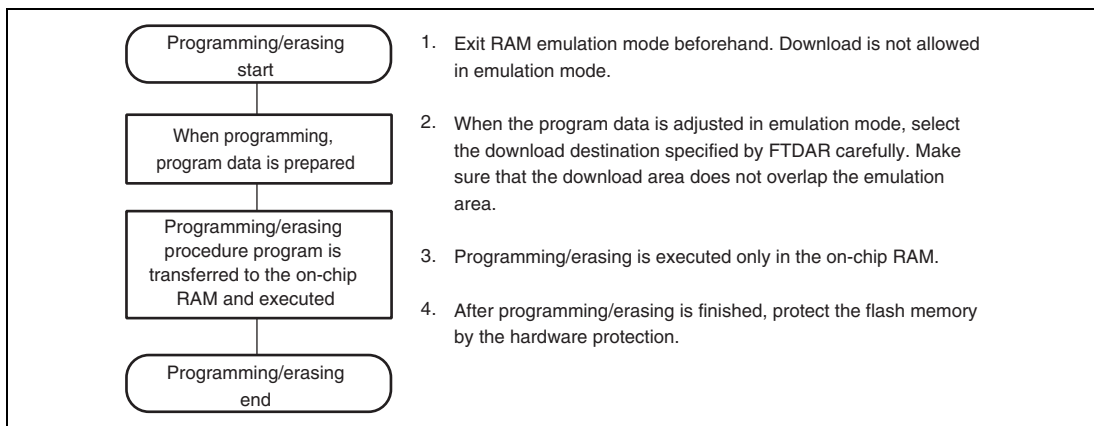

1. After boot mode is initiated, the bit rate of the SCI\_4 is adjusted with that of the host.
2. Inquiry information about the size, configuration, start address, and support status of the user MAT is transmitted to the host.
3. After inquiries have finished, all user MAT and user boot MAT are automatically erased.
4. When the program preparation notice is received, the state of waiting for program data is entered. The start address of the programming destination and program data must be transmitted after the programming command is transmitted. When programming is finished, the start address of the programming destination must be set to H'FFFFFFF and transmitted. Then the state of waiting for program data is returned to the state of waiting for programming/erasing command. When the erasure preparation notice is received, the state of waiting for erase block data is entered. The erase block number must be transmitted after the erasing command is transmitted. When the erasure is finished, the erase block number must be set to H'FF and transmitted. Then the state of waiting for erase block data is returned to the state of waiting for programming/erasing command. Erasure must be executed when the specified block is programmed without a reset start after programming is executed in boot mode. When programming can be executed by only one operation, all blocks are erased before entering the state of waiting for programming/erasing command or another command. Thus, in this case, the erasing operation is not required. The commands other than the programming/erasing command perform sum check, blank check (erasure check), and memory read of the user MAT/user boot MAT and acquisition of current status information.

Memory read of the user MAT/user boot MAT can only read the data programmed after all user MAT/user boot MAT has automatically been erased. No other data can be read.

## 17.8.2 User Program Mode

Programming/erasing of the user MAT is executed by downloading an on-chip program. The user boot MAT cannot be programmed/erased in user program mode. The programming/erasing flow is shown in figure 17.9.

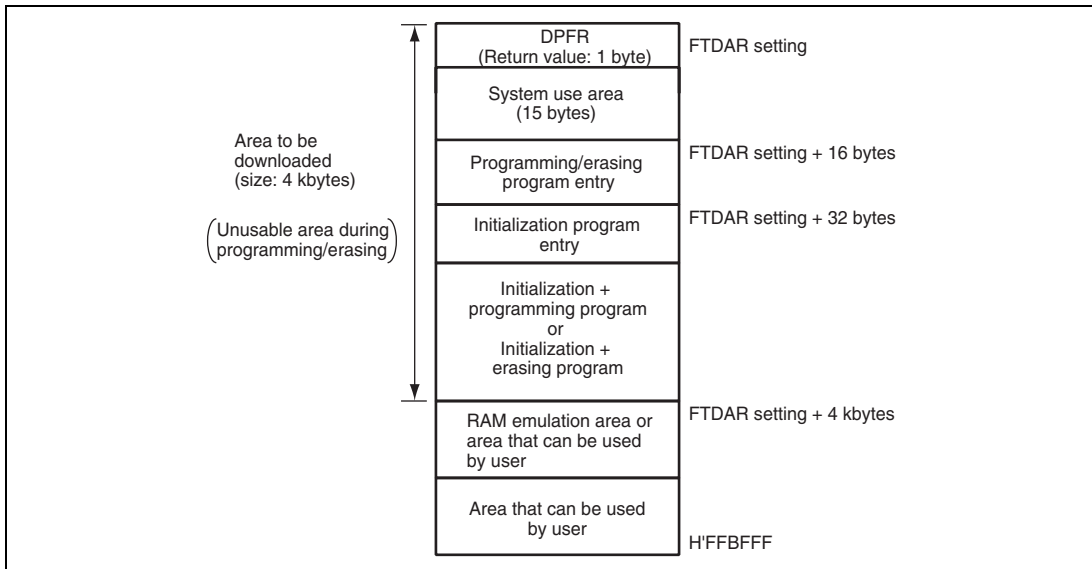

Since high voltage is applied to the internal flash memory during programming/erasing, a transition to the reset state or hardware standby mode must not be made during programming/erasing. A transition to the reset state or hardware standby mode during programming/erasing may damage the flash memory. If a reset is input, the reset must be released after the reset input period (period of  $\overline{\text{RES}} = 0$ ) of at least 100  $\mu\text{s}$ .

**Figure 17.9 Programming/Erasing Flow**

### (1) On-Chip RAM Address Map when Programming/Erasing is Executed

Parts of the procedure program that is made by the user, like download request, programming/erasing procedure, and decision of the result, must be executed in the on-chip RAM. Since the on-chip program to be downloaded is embedded in the on-chip RAM, make sure the on-chip program and procedure program do not overlap. Figure 17.10 shows the area of the on-chip program to be downloaded.

**Figure 17.10 RAM Map when Programming/Erasing is Executed**

## (2) Programming Procedure in User Program Mode

The procedures for download of the on-chip program, initialization, and programming are shown in figure 17.11.

**Figure 17.11 Programming Procedure in User Program Mode**

The procedure program must be executed in an area other than the flash memory to be programmed. Setting the SCO bit in FCCS to 1 to request download must be executed in the on-chip RAM. The area that can be executed in the steps of the procedure program (on-chip RAM and user MAT) is shown in section 17.8.4, On-Chip Program and Storable Area for Program Data. The following description assumes that the area to be programmed on the user MAT is erased and that program data is prepared in the consecutive area.

The program data for one programming operation is always 128 bytes. When the program data exceeds 128 bytes, the start address of the programming destination and program data parameters are updated in 128-byte units and programming is repeated. When the program data is less than 128 bytes, invalid data is filled to prepare 128-byte program data. If the invalid data to be added is H'FF, the program processing time can be shortened.

1. Select the on-chip program to be downloaded and the download destination. When the PPVS bit in FPCS is set to 1, the programming program is selected. Several programming/erasing programs cannot be selected at one time. If several programs are selected, a download error is returned to the SS bit in the DPF<sub>R</sub> parameter. The on-chip RAM start address of the download destination is specified by FTDAR.
2. Write H'A5 in FKEY. If H'A5 is not written to FKEY, the SCO bit in FCCS cannot be set to 1 to request download of the on-chip program.
3. After initializing VBR to H'00000000, set the SCO bit to 1 to execute download. To set the SCO bit to 1, all of the following conditions must be satisfied.
  - RAM emulation mode has been canceled.
  - H'A5 is written to FKEY.
  - Setting the SCO bit is executed in the on-chip RAM.

When the SCO bit is set to 1, download is started automatically. Since the SCO bit is cleared to 0 when the procedure program is resumed, the SCO bit cannot be confirmed to be 1 in the procedure program. The download result can be confirmed by the return value of the DPF<sub>R</sub> parameter. To prevent incorrect decision, before setting the SCO bit to 1, set one byte of the on-chip RAM start address specified by FTDAR, which becomes the DPF<sub>R</sub> parameter, to a value other than the return value (e.g. H'FF). Since particular processing that is accompanied by bank switching as described below is performed when download is executed, initialize the VBR contents to H'00000000. Dummy read of FCCS must be performed twice immediately after the SCO bit is set to 1.

- The user-MAT space is switched to the on-chip program storage area.
- After the program to be downloaded and the on-chip RAM start address specified by FTDAR are checked, they are transferred to the on-chip RAM.
- FPCS, FECS, and the SCO bit in FCCS are cleared to 0.
- The return value is set in the DPF<sub>R</sub> parameter.
- After the on-chip program storage area is returned to the user-MAT space, the procedure program is resumed. After that, VBR can be set again.
- The values of general registers of the CPU are held.
- During download, no interrupts can be accepted. However, since the interrupt requests are held, when the procedure program is resumed, the interrupts are requested.

- To hold a level-detection interrupt request, the interrupt must continue to be input until the download is completed.
  - Allocate a stack area of 128 bytes at the maximum in the on-chip RAM before setting the SCO bit to 1.
  - If access to the flash memory is requested by the DMAC during download, the operation cannot be guaranteed. Make sure that an access request by the DMAC is not generated.
4. FKEY is cleared to H'00 for protection.
  5. The download result must be confirmed by the value of the DPFR parameter. Check the value of the DPFR parameter (one byte of start address of the download destination specified by FTDAR). If the value of the DPFR parameter is H'00, download has been performed normally. If the value is not H'00, the source that caused download to fail can be investigated by the description below.
    - If the value of the DPFR parameter is the same as that before downloading, the setting of the start address of the download destination in FTDAR may be abnormal. In this case, confirm the setting of the TDER bit in FTDAR.
    - If the value of the DPFR parameter is different from that before downloading, check the SS bit or FK bit in the DPFR parameter to confirm the download program selection and FKEY setting, respectively.
  6. The operating frequency and the user branch destination are set to the FPEFEQ and FUBRA parameters, respectively, for initialization.
    - The operating frequency of the CPU is set to the FPEFEQ parameter. The operating frequency settable to the FPEFEQ parameter ranges from 8 to 48 MHz. When a value out of this frequency range is set, an error is returned to the FPFR parameter of the initialization program and initialization is not performed. For details on the frequency setting, see the description in (3) Flash Program/Erase Frequency Parameter (FPEFEQ) of 17.7.2 Programming/Erasing Interface Parameters.
    - The start address in the user branch destination is set to the FUBRA parameter. When the user branch processing is not required, H'00000000 must be set to FUBRA. When the user branch is executed, the branch destination is executed in flash memory other than the one that is to be programmed. The area of the on-chip program that is downloaded cannot be set. The program processing must be returned from the user branch processing by the RTS instruction. See the description in (7) Flash User Branch Address Set Parameter (FUBRA) of 17.7.2 Programming/Erasing Interface Parameters.

7. Initialization is executed. The initialization program is downloaded together with the programming program to the on-chip RAM. The entry point of the initialization program is at the address which is 32 bytes after #DLTOP (when the start address of the download destination specified by FTDAR is #DLTOP). Call the subroutine to execute initialization by using the following steps.

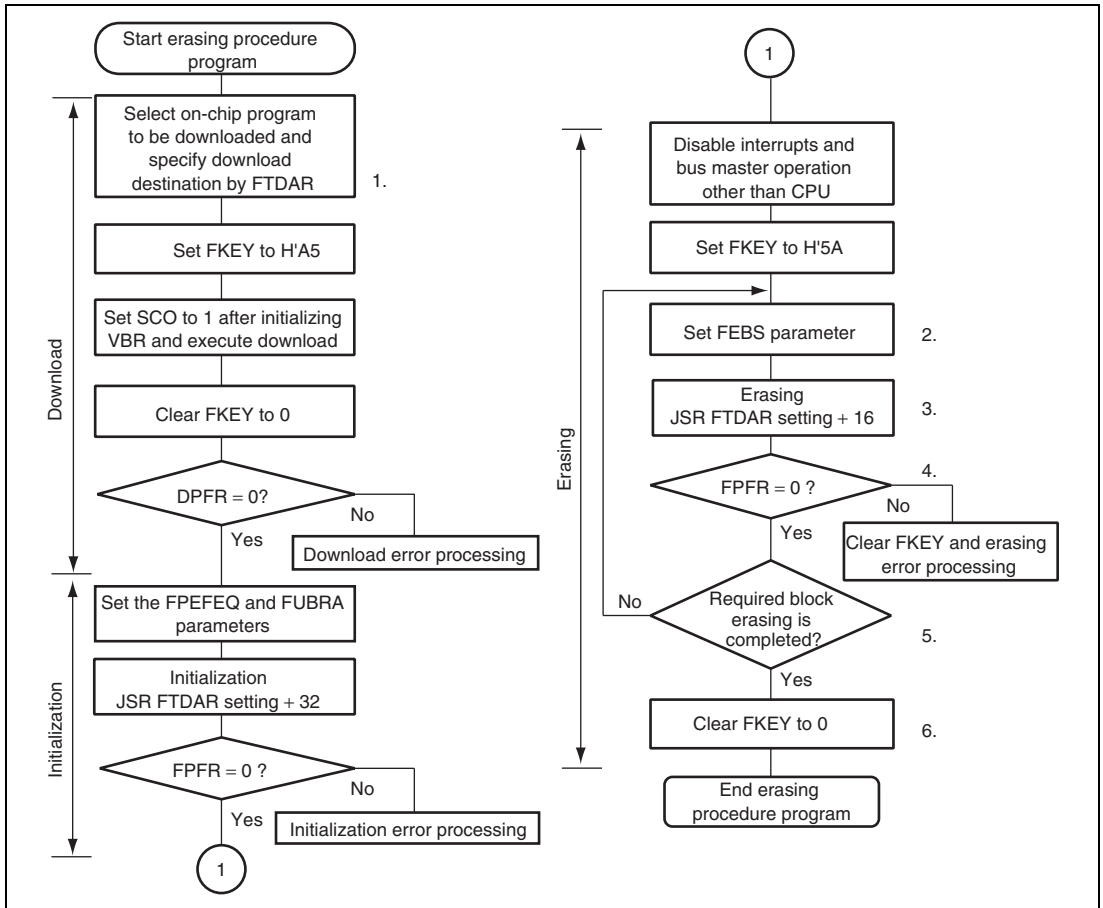

```
MOV.L #DLTOP+32,ER2    ; Set entry address to ER2
JSR   @ER2             ; Call initialization routine
NOP
```

- The general registers other than ER0 and ER1 are held in the initialization program.
  - R0L is a return value of the FPFRR parameter.
  - Since the stack area is used in the initialization program, a stack area of 128 bytes at the maximum must be allocated in RAM.
  - Interrupts can be accepted during execution of the initialization program. Make sure the program storage area and stack area in the on-chip RAM and register values are not overwritten.
8. The return value in the initialization program, the FPFRR parameter is determined.
9. All interrupts and the use of a bus master other than the CPU are disabled during programming/erasing. The specified voltage is applied for the specified time when programming or erasing. If interrupts occur or the bus mastership is moved to other than the CPU during programming/erasing, causing a voltage exceeding the specifications to be applied, the flash memory may be damaged. Therefore, interrupts are disabled by setting bit 7 (I bit) in the condition code register (CCR) to B'1 in interrupt control mode 0 and by setting bits 2 to 0 (I2 to I0 bits) in the extend register (EXR) to B'111 in interrupt control mode 2. Accordingly, interrupts other than NMI are held and not executed. Configure the user system so that NMI interrupts do not occur. The interrupts that are held must be executed after all programming completes. When the bus mastership is moved to other than the CPU, such as to the DMAC, the error protection state is entered. Therefore, make sure the DMAC does not acquire the bus.
10. FKEY must be set to H'5A and the user MAT must be prepared for programming.

11. The parameters required for programming are set. The start address of the programming destination on the user MAT (FMPAR parameter) is set in general register ER1. The start address of the program data storage area (FMPDR parameter) is set in general register ER0.
- Example of FMPAR parameter setting: When an address other than one in the user MAT area is specified for the start address of the programming destination, even if the programming program is executed, programming is not executed and an error is returned to the FPFR parameter. Since the program data for one programming operation is 128 bytes, the lower eight bits of the address must be H'00 or H'80 to be aligned with the 128-byte boundary.
  - Example of FMPDR parameter setting: When the storage destination for the program data is flash memory, even if the programming routine is executed, programming is not executed and an error is returned to the FPFR parameter. In this case, the program data must be transferred to the on-chip RAM and then programming must be executed.
12. Programming is executed. The entry point of the programming program is at the address which is 16 bytes after #DLTOP (when start address of the download destination specified by FTDAR is #DLTOP). Call the subroutine to execute programming by using the following steps.
- |       |               |                            |
|-------|---------------|----------------------------|
| MOV.L | #DLTOP+16,ER2 | ; Set entry address to ER2 |
| JSR   | @ER2          | ; Call programming routine |
| NOP   |               |                            |
- The general registers other than ER0 and ER1 are held in the programming program.
  - R0L is a return value of the FPFR parameter.
  - Since the stack area is used in the programming program, a stack area of 128 bytes at the maximum must be allocated in RAM.
13. The return value in the programming program, the FPFR parameter is determined.
14. Determine whether programming of the necessary data has finished. If more than 128 bytes of data are to be programmed, update the FMPAR and FMPDR parameters in 128-byte units, and repeat steps 11 to 14. Increment the programming destination address by 128 bytes and update the programming data pointer correctly. If an address which has already been programmed is written to again, not only will a programming error occur, but also flash memory will be damaged.
15. After programming finishes, clear FKEY and specify software protection. If this LSI is restarted by a reset immediately after programming has finished, secure the reset input period (period of RES = 0) of at least 100  $\mu$ s.

### (3) Erasing Procedure in User Program Mode

The procedures for download of the on-chip program, initialization, and erasing are shown in figure 17.12.

**Figure 17.12 Erasing Procedure in User Program Mode**

The procedure program must be executed in an area other than the user MAT to be erased. Setting the SCO bit in FCCS to 1 to request download must be executed in the on-chip RAM. The area that can be executed in the steps of the procedure program (on-chip RAM and user MAT) is shown in section 17.8.4, On-Chip Program and Storable Area for Program Data. For the downloaded on-chip program area, see figure 17.10.

One erasure processing erases one block. For details on block divisions, refer to figure 17.4. To erase two or more blocks, update the erase block number and repeat the erasing processing for each block.

1. Select the on-chip program to be downloaded and the download destination. When the PPVS bit in FPCS is set to 1, the programming program is selected. Several programming/erasing programs cannot be selected at one time. If several programs are selected, a download error is returned to the SS bit in the DPF<sub>R</sub> parameter. The on-chip RAM start address of the download destination is specified by FTDAR.

For the procedures to be carried out after setting FKEY, see section 17.8.2 (2), Programming Procedure in User Program Mode.

2. Set the FEBS parameter necessary for erasure. Set the erase block number (FEBS parameter) of the user MAT in general register ER0. If a value other than an erase block number of the user MAT is set, no block is erased even though the erasing program is executed, and an error is returned to the FPF<sub>R</sub> parameter.
3. Erasure is executed. Similar to as in programming, the entry point of the erasing program is at the address which is 16 bytes after #DLTOP (when the start address of the download destination specified by FTDAR is #DLTOP). Call the subroutine to execute erasure by using the following steps.

```
MOV.L #DLTOP+16, ER2      ; Set entry address to ER2
JSR  @ER2                 ; Call erasing routine
NOP
```

- The general registers other than ER0 and ER1 are held in the erasing program.
  - R0L is a return value of the FPF<sub>R</sub> parameter.
  - Since the stack area is used in the erasing program, a stack area of 128 bytes at the maximum must be allocated in RAM.
4. The return value in the erasing program, the FPF<sub>R</sub> parameter is determined.
  5. Determine whether erasure of the necessary blocks has finished. If more than one block is to be erased, update the FEBS parameter and repeat steps 2 to 5.
  6. After erasure completes, clear FKEY and specify software protection. If this LSI is restarted by a power-on reset immediately after erasure has finished, secure the reset input period (period of  $\overline{\text{RES}} = 0$ ) of at least 100  $\mu$ s.

#### (4) Procedure of Erasing, Programming, and RAM Emulation in User Program Mode

By changing the on-chip RAM start address of the download destination in FTDAR, the erasing program and programming program can be downloaded to separate on-chip RAM areas.

Figure 17.13 shows a repeating procedure of erasing, programming, and RAM emulation.

**Figure 17.13 Repeating Procedure of Erasing, Programming, and RAM Emulation in User Program Mode**

In figure 17.13, since RAM emulation is performed, the erasing/programming program is downloaded to avoid the 4-kbyte on-chip RAM area (H'FFFA000 to H'FFFAFFF). Download and initialization are performed only once at the beginning. Note the following when executing the procedure program.

- Be careful not to overwrite data in the on-chip RAM with overlay settings. In addition to the programming program area, erasing program area, and RAM emulation area, areas for the procedure programs, work area, and stack area are reserved in the on-chip RAM. Do not make settings that will overwrite data in these areas.
- Be sure to initialize both the programming program and erasing program. When the FPEFEQ and FUBRA parameters are initialized, also initialize both the erasing program and programming program. Initialization must be executed for both entry addresses: 32 bytes after #DLTOP (when the start address of download destination for erasing program is #DLTOP), and 32 bytes after #DLTOP (when the start address of download destination for programming program is #DLTOP).

### 17.8.3 User Boot Mode

Branching to a programming/erasing program prepared by the user enables user boot mode which is a user-arbitrary boot mode to be used.

Only the user MAT can be programmed/erased in user boot mode. Programming/erasing of the user boot MAT is only enabled in boot mode or programmer mode.

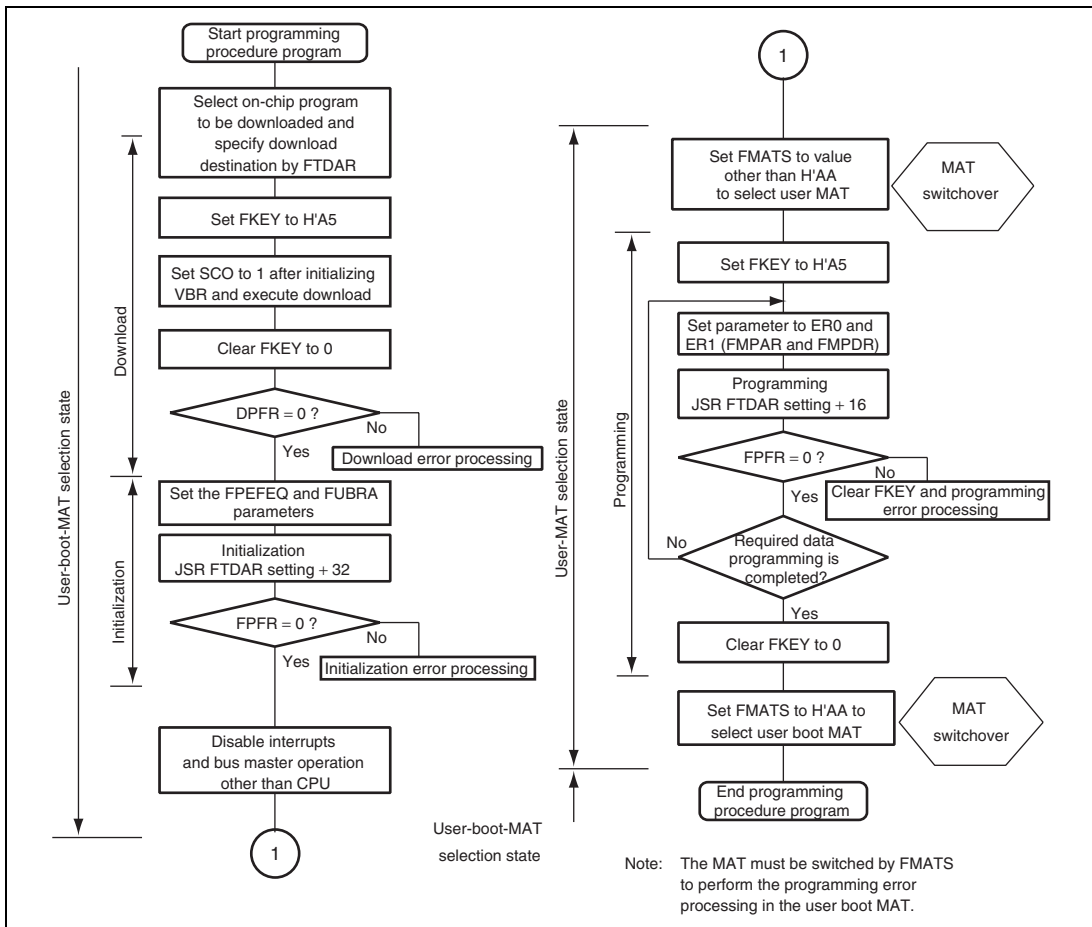

#### (1) Initiation in User Boot Mode

When the reset start is executed with the mode pins set to user boot mode, the built-in check routine runs and checks the user MAT and user boot MAT states. While the check routine is running, NMI and all other interrupts cannot be accepted. Next, processing starts from the execution start address of the reset vector in the user boot MAT. At this point, the user boot MAT is selected (FMATS = H'AA) as the execution memory MAT.

## (2) User MAT Programming in User Boot Mode

Figure 17.14 shows the procedure for programming the user MAT in user boot mode.

The difference between the programming procedures in user program mode and user boot mode is the memory MAT switching as shown in figure 17.14. For programming the user MAT in user boot mode, additional processing made by setting FMATS is required: switching from the user boot MAT to the user MAT, and switching back to the user boot MAT after programming completes.

**Figure 17.14 Procedure for Programming User MAT in User Boot Mode**

In user boot mode, though the user boot MAT can be seen in the flash memory space, the user MAT is hidden in the background. Therefore, the user MAT and user boot MAT are switched while the user MAT is being programmed. Because the user boot MAT is hidden while the user MAT is being programmed, the procedure program must be executed in an area other than flash memory. After programming completes, switch the memory MATs again to return to the first state.

Memory MAT switching is enabled by setting FMATS. However note that access to a memory MAT is not allowed until memory MAT switching is completed. During memory MAT switching, the LSI is in an unstable state, e.g. if an interrupt occurs, from which memory MAT the interrupt vector is read is undetermined. Perform memory MAT switching in accordance with the description in section 17.11, Switching between User MAT and User Boot MAT.

Except for memory MAT switching, the programming procedure is the same as that in user program mode.

The area that can be executed in the steps of the procedure program (on-chip RAM, user MAT, and external space) is shown in section 17.8.4, On-Chip Program and Storable Area for Program Data.

### **(3) User MAT Erasing in User Boot Mode**

Figure 17.15 shows the procedure for erasing the user MAT in user boot mode.

The difference between the erasing procedures in user program mode and user boot mode is the memory MAT switching as shown in figure 17.15. For erasing the user MAT in user boot mode, additional processing made by setting FMATS is required: switching from the user boot MAT to the user MAT, and switching back to the user boot MAT after erasing completes.

**Figure 17.15 Procedure for Erasing User MAT in User Boot Mode**

Memory MAT switching is enabled by setting FMATS. However note that access to a memory MAT is not allowed until memory MAT switching is completed. During memory MAT switching, the LSI is in an unstable state, e.g. if an interrupt occurs, from which memory MAT the interrupt vector is read is undetermined. Perform memory MAT switching in accordance with the description in section 17.11, Switching between User MAT and User Boot MAT.

Except for memory MAT switching, the erasing procedure is the same as that in user program mode.

The area that can be executed in the steps of the procedure program (on-chip RAM, user MAT, and external space) is shown in section 17.8.4, On-Chip Program and Storable Area for Program Data.

### 17.8.4 On-Chip Program and Storable Area for Program Data

In the descriptions in this manual, the on-chip programs and program data storage areas are assumed to be in the on-chip RAM. However, they can be executed from part of the flash memory which is not to be programmed or erased as long as the following conditions are satisfied.

- The on-chip program is downloaded to and executed in the on-chip RAM specified by FTDAR. Therefore, this on-chip RAM area is not available for use.
- Since the on-chip program uses a stack area, allocate 128 bytes at the maximum as a stack area.
- Download requested by setting the SCO bit in FCCS to 1 should be executed from the on-chip RAM because it will require switching of the memory MATs.
- In an operating mode in which the external address space is not accessible, such as single-chip mode, the required procedure programs, NMI handling vector table, and NMI handling routine should be transferred to the on-chip RAM before programming/erasing starts (download result is determined).
- The flash memory is not accessible during programming/erasing. Programming/erasing is executed by the program downloaded to the on-chip RAM. Therefore, the procedure program that initiates operation, the user program at the user branch destination for programming/erasing, the NMI handling vector table, and the NMI handling routine should be stored in the on-chip RAM other than the flash memory.
- After programming/erasing starts, access to the flash memory should be inhibited until FKEY is cleared. The reset input state (period of  $\overline{\text{RES}} = 0$ ) must be set to at least 100  $\mu$ s when the operating mode is changed and the reset start executed on completion of programming/erasing. Transitions to the reset state are inhibited during programming/erasing. When the reset signal is input, a reset input state (period of  $\overline{\text{RES}} = 0$ ) of at least 100  $\mu$ s is needed before the reset signal is released.
- Switching of the memory MATs by FMATS should be needed when programming/erasing of the user MAT is operated in user boot mode. The program which switches the memory MATs should be executed from the on-chip RAM. For details, see section 17.11, Switching between User MAT and User Boot MAT. Make sure you know which memory MAT is currently selected when switching them.
- When the program data storage area is within the flash memory area, an error will occur even when the data stored is normal program data. Therefore, the data should be transferred to the on-chip RAM to place the address that the FMPDR parameter indicates in an area other than the flash memory.

In consideration of these conditions, the areas in which the program data can be stored and executed are determined by the combination of the processing contents, operating mode, and bank structure of the memory MATs, as shown in tables 17.7 to 17.11.

**Table 17.7 Executable Memory MAT**

<b>Processing Contents</b>	<b>Operating Mode</b>	
	<b>User Program Mode</b>	<b>User Boot Mode*</b>
Programming	See table 17.8	See table 17.10
Erasing	See table 17.9	See table 17.11

Note: \* Programming/Erasing is possible to the user MAT.

**Table 17.8 Usable Area for Programming in User Program Mode**

Item	Storable/Executable Area		Selected MAT

Switching memory MATs by FMATS	O	×	O		

Note: Switching memory MATs by FMATS by a program in the on-chip RAM enables this area to be used.

## 17.9 Protection

There are three types of protection against the flash memory programming/erasing: hardware protection, software protection, and error protection.

### 17.9.1 Hardware Protection

Programming and erasure of the flash memory is forcibly disabled or suspended by hardware protection. In this state, download of an on-chip program and initialization are possible. However, programming or erasure of the user MAT cannot be performed even if the programming/erasing program is initiated, and the error in programming/erasing is indicated by the FPFR parameter.

**Table 17.12 Hardware Protection**

Item	Description	Function to be Protected	
		Download	Programming/ Erasing
Reset protection	<ul style="list-style-type: none"> <li>The programming/erasing interface registers are initialized in the reset state (including a reset by the WDT) and the programming/erasing protection state is entered.</li> <li>The reset state will not be entered by a reset using the <math>\overline{\text{RES}}</math> pin unless the <math>\overline{\text{RES}}</math> pin is held low until oscillation has settled after a power is initially supplied. In the case of a reset during operation, hold the <math>\overline{\text{RES}}</math> pin low for the <math>\overline{\text{RES}}</math> pulse width given in the AC characteristics. If a reset is input during programming or erasure, data in the flash memory is not guaranteed. In this case, execute erasure and then execute programming again.</li> </ul>	O	O

## 17.9.2 Software Protection

The software protection protects the flash memory against programming/erasing by disabling download of the programming/erasing program, using the key code, and by the RAMER setting.

**Table 17.13 Software Protection**

Item	Description	Function to be Protected	
		Download	Programming/ Erasing
Protection by SCO bit	<ul style="list-style-type: none"> <li>The programming/erasing protection state is entered when the SCO bit in FCCS is cleared to 0 to disable download of the programming/erasing programs.</li> </ul>	○	○
Protection by FKEY	<ul style="list-style-type: none"> <li>The programming/erasing protection state is entered because download and programming/erasing are disabled unless the required key code is written in FKEY.</li> </ul>	○	○
Emulation protection	<ul style="list-style-type: none"> <li>The programming/erasing protection state is entered when the RAMS bit in the RAM emulation register (RAMER) is set to 1.</li> </ul>	○	○

## 17.9.3 Error Protection

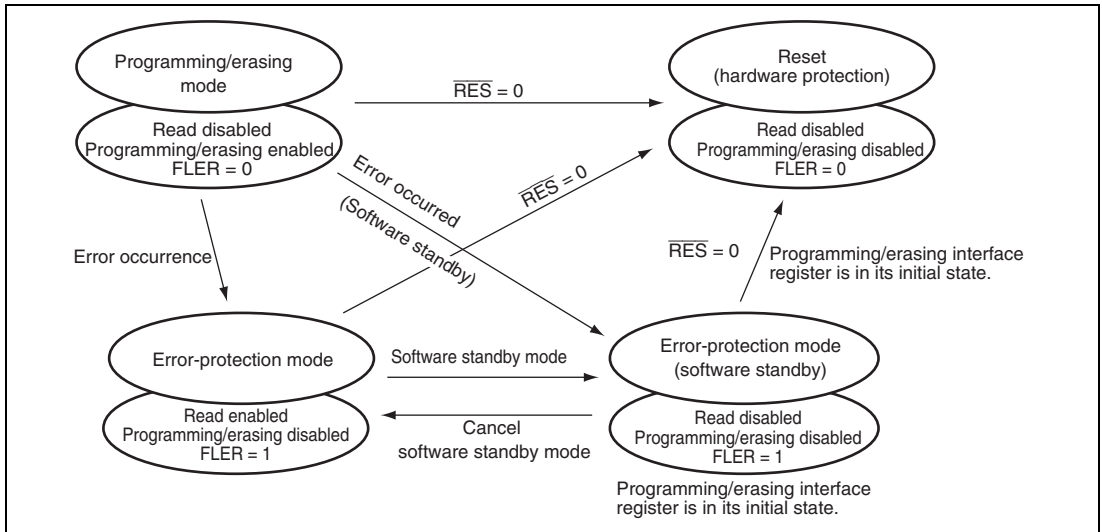

Error protection is a mechanism for aborting programming or erasure when a CPU runaway occurs or operations not according to the programming/erasing procedures are detected during programming/erasing of the flash memory. Aborting programming or erasure in such cases prevents damage to the flash memory due to excessive programming or erasing.

If an error occurs during programming/erasing of the flash memory, the FLER bit in FCCS is set to 1 and the error protection state is entered.

- When an interrupt request, such as NMI, occurs during programming/erasing.
- When the flash memory is read from during programming/erasing (including a vector read or an instruction fetch).
- When a SLEEP instruction is executed (including software-standby mode) during programming/erasing.
- When a bus master other than the CPU, such as the DMAC, obtains bus mastership during programming/erasing.

Error protection is canceled by a reset. Note that the reset should be released after the reset input period of at least 100  $\mu\text{s}$  has passed. Since high voltages are applied during programming/erasing of the flash memory, some voltage may remain after the error protection state has been entered. For this reason, it is necessary to reduce the risk of damaging the flash memory by extending the reset input period so that the charge is released.

The state-transition diagram in figure 17.16 shows transitions to and from the error protection state.

**Figure 17.16 Transitions to Error Protection State**

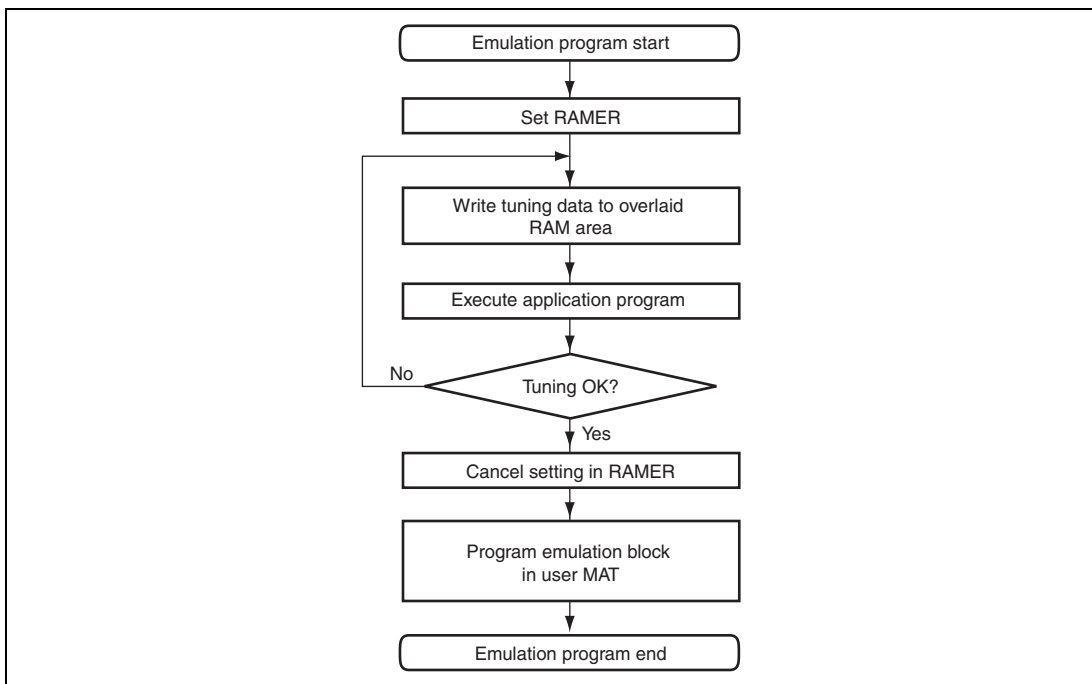

## 17.10 Flash Memory Emulation Using RAM

For realtime emulation of the data written to the flash memory using the on-chip RAM, the on-chip RAM area can be overlaid with several flash memory blocks (user MAT) using the RAM emulation register (RAMER).

The overlaid area can be accessed from both the user MAT area specified by RAMER and the overlaid RAM area. The emulation can be performed in user mode and user program mode.

Figure 17.17 shows an example of emulating realtime programming of the user MAT.

Note: When performing the flash memory emulation using the RAM, set the RAME bit in the system control register (SYSCR).

**Figure 17.17 RAM Emulation Flow**

Figure 17.19 shows an example of the procedure to program the tuned data in block EB0 of the user MAT.

**Figure 17.19 Programming Tuned Data**

1. After tuning program data is completed, clear the RAMS bit in RAMER to 0 to cancel the overlaid RAM.
2. Transfer the user-created procedure program to the on-chip RAM.
3. Start the procedure program and download the on-chip program to the on-chip RAM. The start address of the download destination should be specified by FTDAR so that the tuned data area does not overlay the download area.
4. When block EB0 of the user MAT has not been erased, the programming program must be downloaded after block EB0 is erased. Specify the tuned data saved in the FMPAR and FMPDR parameters and then execute programming.

Note: Setting the RAMS bit to 1 makes all the blocks of the user MAT enter the programming/erasing protection state (emulation protection state) regardless of the setting of the RAM2 to RAM0 bits. Under this condition, the on-chip program cannot be downloaded. When data is to be actually programmed and erased, clear the RAMS bit to 0.

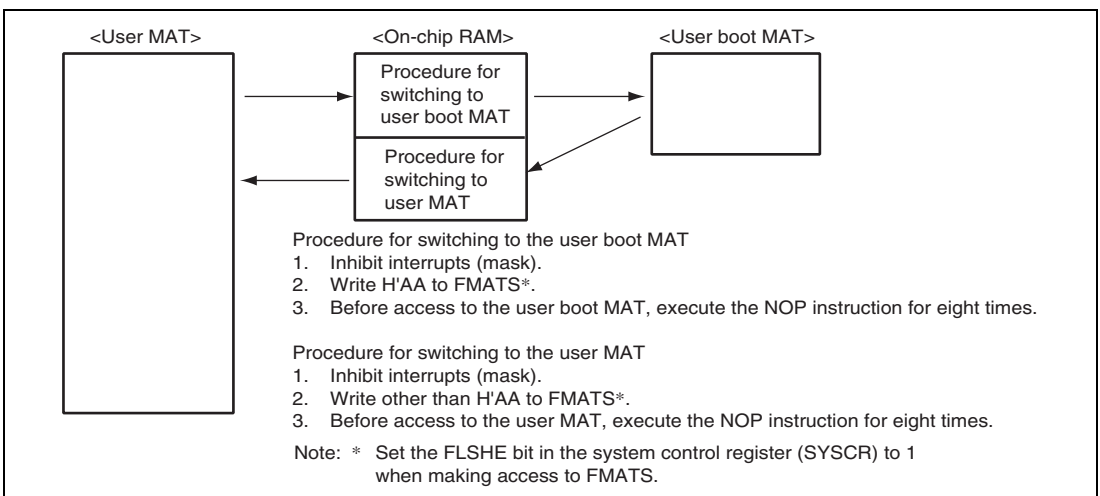

## 17.11 Switching between User MAT and User Boot MAT

It is possible to switch between the user MAT and user boot MAT. However, the following procedure is required because the start addresses of these MATs are allocated to the same address.

Switching to the user boot MAT disables programming and erasing. Programming of the user boot MAT should take place in boot mode or programmer mode.

1. Memory MAT switching by FMATS should always be executed from the on-chip RAM.
2. When accessing the memory MAT immediately after switching the memory MATs by FMATS from the on-chip RAM, similarly execute the NOP instruction in the on-chip RAM for eight times (this prevents access to the flash memory during memory MAT switching).
3. If an interrupt request has occurred during memory MAT switching, there is no guarantee of which memory MAT is accessed. Always mask the maskable interrupts before switching memory MATs. In addition, configure the system so that NMI interrupts do not occur during memory MAT switching.
4. After the memory MATs have been switched, take care because the interrupt vector table will also have been switched. If interrupt processing is to be the same before and after memory MAT switching, transfer the interrupt processing routines to the on-chip RAM and specify VBR to place the interrupt vector table in the on-chip RAM.
5. Memory sizes of the user MAT and user boot MAT are different. When accessing the user boot MAT, do not access addresses which exceed the 10-kbyte memory space. If an access is equal to or greater than 10 kbytes, the read values are undefined.

**Figure 17.20 Switching between User MAT and User Boot MAT**

## 17.12 Programmer Mode

Along with its on-board programming mode, this LSI also has a programmer mode as a further mode for the writing and erasing of programs and data. In programmer mode, a general-purpose PROM programmer that supports the device types shown in table 17.14 can be used to write programs to the on-chip ROM without any limitation.

**Table 17.14 Device Types Supported in Programmer Mode**

Target Memory MAT	Size	Device Type
User MAT	256 kbytes	FZTAT256V5A
User boot MAT	10 kbytes	FZTATUSBTV5A

## 17.13 Standard Serial Communication Interface Specifications for Boot Mode

The boot program initiated in boot mode performs serial communication using the host and on-chip SCI\_4. The serial communication interface specifications are shown below.

The boot program has three states.

1. Bit-rate-adjustment state

In this state, the boot program adjusts the bit rate to achieve serial communication with the host. Initiating boot mode enables starting of the boot program and entry to the bit-rate-adjustment state. The program receives the command from the host to adjust the bit rate. After adjusting the bit rate, the program enters the inquiry/selection state.

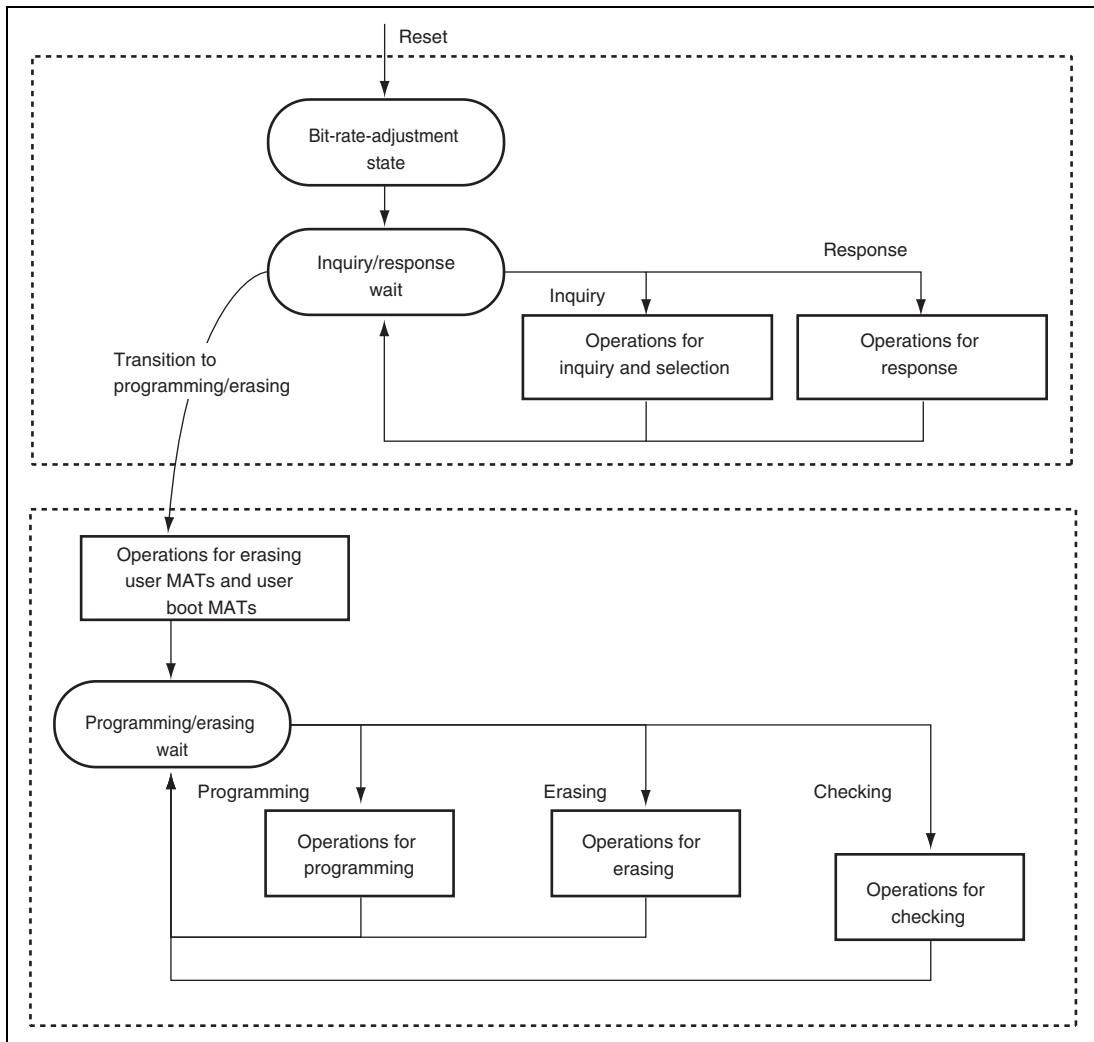

2. Inquiry/selection state

In this state, the boot program responds to inquiry commands from the host. The device name, clock mode, and bit rate are selected. After selection of these settings, the program is made to enter the programming/erasing state by the command for a transition to the programming/erasing state. The program transfers the libraries required for erasure to the on-chip RAM and erases the user MATs and user boot MATs before the transition.

3. Programming/erasing state

Programming and erasure by the boot program take place in this state. The boot program is made to transfer the programming/erasing programs to the on-chip RAM by commands from the host. Sum checks and blank checks are executed by sending these commands from the host.

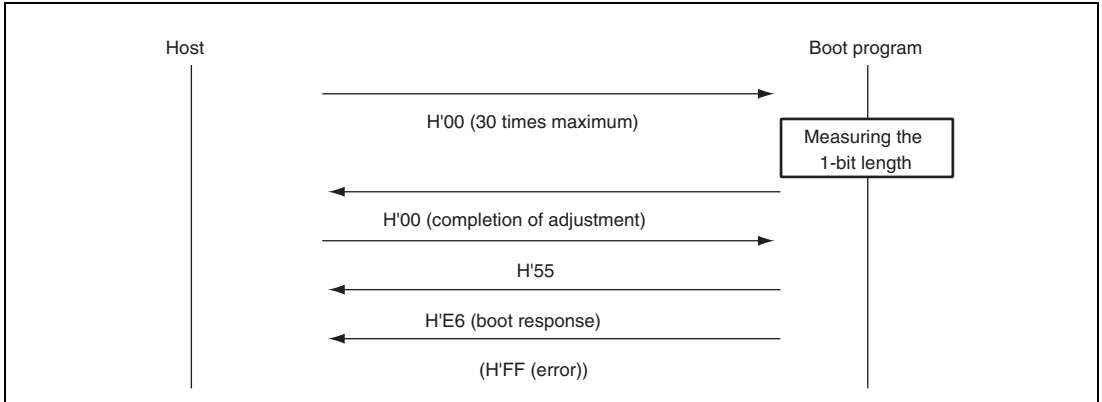

These boot program states are shown in figure 17.21.

**Figure 17.21 Boot Program States**

## (1) Bit-Rate-Adjustment State

The bit rate is calculated by measuring the period of transfer of a low-level byte (H'00) from the host. The bit rate can be changed by the command for a new bit rate selection. After the bit rate has been adjusted, the boot program enters the inquiry and selection state. The bit-rate-adjustment sequence is shown in figure 17.22.

**Figure 17.22 Bit-Rate-Adjustment Sequence**

## (2) Communications Protocol

After adjustment of the bit rate, the protocol for serial communications between the host and the boot program is as shown below.

### 1. One-byte commands and one-byte responses

These one-byte commands and one-byte responses consist of the inquiries and the ACK for successful completion.

### 2. n-byte commands or n-byte responses

These commands and responses are comprised of n bytes of data. These are selections and responses to inquiries.

The program data size is not included under this heading because it is determined in another command.

### 3. Error response

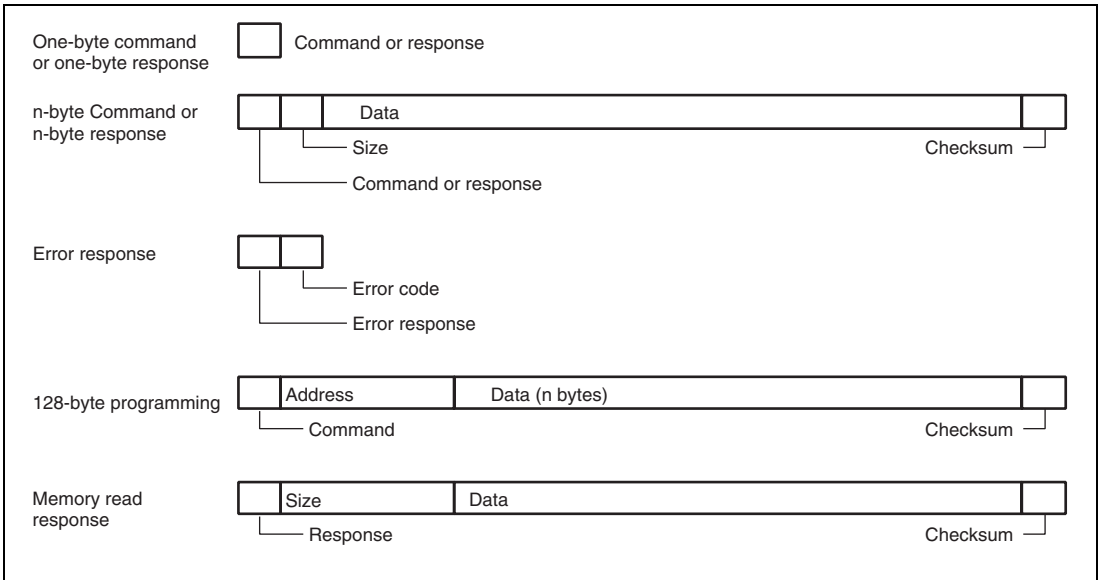

The error response is a response to inquiries. It consists of an error response and an error code and comes two bytes.

### 4. Programming of 128 bytes

The size is not specified in commands. The size of n is indicated in response to the programming unit inquiry.

## 5. Memory read response

This response consists of four bytes of data.

**Figure 17.23 Communication Protocol Format**

- **Command (one byte):** Commands including inquiries, selection, programming, erasing, and checking
- **Response (one byte):** Response to an inquiry
- **Size (one byte):** The amount of data for transmission excluding the command, amount of data, and checksum
- **Checksum (one byte):** The checksum is calculated so that the total of all values from the command byte to the SUM byte becomes H'00.
- **Data (n bytes):** Detailed data of a command or response
- **Error response (one byte):** Error response to a command
- **Error code (one byte):** Type of the error
- **Address (four bytes):** Address for programming
- **Data (n bytes):** Data to be programmed (the size is indicated in the response to the programming unit inquiry.)
- **Size (four bytes):** Four-byte response to a memory read

### (3) Inquiry and Selection States

The boot program returns information from the flash memory in response to the host's inquiry commands and sets the device code, clock mode, and bit rate in response to the host's selection command.

Table 17.15 lists the inquiry and selection commands.

**Table 17.15 Inquiry and Selection Commands**

<b>Command</b>	<b>Command Name</b>	<b>Description</b>
H'20	Supported device inquiry	Inquiry regarding device codes
H'10	Device selection	Selection of device code
H'21	Clock mode inquiry	Inquiry regarding numbers of clock modes and values of each mode
H'11	Clock mode selection	Indication of the selected clock mode
H'22	Multiplication ratio inquiry	Inquiry regarding the number of frequency-multiplied clock types, the number of multiplication ratios, and the values of each multiple
H'23	Operating clock frequency inquiry	Inquiry regarding the maximum and minimum values of the main clock and peripheral clocks
H'24	User boot MAT information inquiry	Inquiry regarding the number of user boot MATs and the start and last addresses of each MAT
H'25	User MAT information inquiry	Inquiry regarding the a number of user MATs and the start and last addresses of each MAT
H'26	Block for erasing information Inquiry	Inquiry regarding the number of blocks and the start and last addresses of each block
H'27	Programming unit inquiry	Inquiry regarding the unit of program data
H'3F	New bit rate selection	Selection of new bit rate
H'40	Transition to programming/erasing state	Erasing of user MAT and user boot MAT, and entry to programming/erasing state
H'4F	Boot program status inquiry	Inquiry into the operated status of the boot program

The selection commands, which are device selection (H'10), clock mode selection (H'11), and new bit rate selection (H'3F), should be sent from the host in that order. When two or more selection commands are sent at once, the last command will be valid.

All of these commands, except for the boot program status inquiry command (H'4F), will be valid until the boot program receives the programming/erasing transition (H'40). The host can choose the needed commands and make inquiries while the above commands are being transmitted. H'4F is valid even after the boot program has received H'40.

### (a) Supported Device Inquiry

The boot program will return the device codes of supported devices and the product code in response to the supported device inquiry.

Command 

H'20
------

- Command, H'20, (one byte): Inquiry regarding supported devices

Response	H'30	Size	Number of devices	
	Number of characters	Device code		Product name
	...			
	SUM			

- Response, H'30, (one byte): Response to the supported device inquiry
- Size (one byte): Number of bytes to be transmitted, excluding the command, size, and checksum, that is, the amount of data contributes by the number of devices, characters, device codes and product names
- Number of devices (one byte): The number of device types supported by the boot program
- Number of characters (one byte): The number of characters in the device codes and boot program's name
- Device code (four bytes): ASCII code of the supporting product
- Product name (n bytes): Type name of the boot program in ASCII-coded characters
- SUM (one byte): Checksum

The checksum is calculated so that the total number of all values from the command byte to the SUM byte becomes H'00.

**(b) Device Selection**

The boot program will set the supported device to the specified device code. The program will return the selected device code in response to the inquiry after this setting has been made.

Command	H'10	Size	Device code	SUM
---------	------	------	-------------	-----

- Command, H'10, (one byte): Device selection
- Size (one byte): Amount of device-code data  
This is fixed at 4.
- Device code (four bytes): Device code (ASCII code) returned in response to the supported device inquiry
- SUM (one byte): Checksum

Response	H'06
----------	------

- Response, H'06, (one byte): Response to the device selection command  
ACK will be returned when the device code matches.

Error response	H'90	ERROR
----------------	------	-------

- Error response, H'90, (one byte): Error response to the device selection command  
ERROR : (one byte): Error code  
H'11: Sum check error  
H'21: Device code error, that is, the device code does not match

**(c) Clock Mode Inquiry**

The boot program will return the supported clock modes in response to the clock mode inquiry.

Command	H'21
---------	------

- Command, H'21, (one byte): Inquiry regarding clock mode

Response	H'31	Size	Number of modes	Mode	...	SUM
----------	------	------	-----------------	------	-----	-----

- Response, H'31, (one byte): Response to the clock-mode inquiry
- Size (one byte): Amount of data that represents the number of modes and modes
- Number of clock modes (one byte): The number of supported clock modes  
H'00 indicates no clock mode or the device allows to read the clock mode.
- Mode (one byte): Values of the supported clock modes (i.e. H'01 means clock mode 1.)
- SUM (one byte): Checksum

**(d) Clock Mode Selection**

The boot program will set the specified clock mode. The program will return the selected clock-mode information after this setting has been made.

The clock-mode selection command should be sent after the device-selection commands.

Command 

H'11	Size	Mode	SUM
------	------	------	-----

- Command, H'11, (one byte): Selection of clock mode
- Size (one byte): Amount of data that represents the modes
- Mode (one byte): A clock mode returned in reply to the supported clock mode inquiry.
- SUM (one byte): Checksum

Response 

H'06
------

- Response, H'06, (one byte): Response to the clock mode selection command  
ACK will be returned when the clock mode matches.

Error Response 

H'91	ERROR
------	-------

- Error response, H'91, (one byte): Error response to the clock mode selection command
- ERROR : (one byte): Error code  
H'11: Checksum error  
H'22: Clock mode error, that is, the clock mode does not match.

Even if the clock mode numbers are H'00 and H'01 by a clock mode inquiry, the clock mode must be selected using these respective values.

**(e) Multiplication Ratio Inquiry**

The boot program will return the supported multiplication and division ratios.

Command 

H'22
------

- Command, H'22, (one byte): Inquiry regarding multiplication ratio

Response	H'32	Size	Number of types					
	Number of multiplication ratios	Multiplication ratio	...					
	...							
	SUM							

- Response, H'32, (one byte): Response to the multiplication ratio inquiry
- Size (one byte): The amount of data that represents the number of clock sources and multiplication ratios and the multiplication ratios
- Number of types (one byte): The number of supported multiplied clock types (e.g. when there are two multiplied clock types, which are the main and peripheral clocks, the number of types will be H'02.)
- Number of multiplication ratios (one byte): The number of multiplication ratios for each type (e.g. the number of multiplication ratios to which the main clock can be set and the peripheral clock can be set.)
- Multiplication ratio (one byte)
- Multiplication ratio: The value of the multiplication ratio (e.g. when the clock-frequency multiplier is four, the value of multiplication ratio will be H'04.)

Division ratio: The inverse of the division ratio, i.e. a negative number (e.g. when the clock is divided by two, the value of division ratio will be H'FE.  $H'FE = D'-2$ )

The number of multiplication ratios returned is the same as the number of multiplication ratios and as many groups of data are returned as there are types.

- SUM (one byte): Checksum

**(f) Operating Clock Frequency Inquiry**

The boot program will return the number of operating clock frequencies, and the maximum and minimum values.

Command 

H'23
------

- Command, H'23, (one byte): Inquiry regarding operating clock frequencies

Response	H'33	Size	Number of operating clock frequencies
	Minimum value of operating clock frequency		Maximum value of operating clock frequency
	...		
	SUM		

- Response, H'33, (one byte): Response to operating clock frequency inquiry
- Size (one byte): The number of bytes that represents the minimum values, maximum values, and the number of frequencies.
- Number of operating clock frequencies (one byte): The number of supported operating clock frequency types  
(e.g. when there are two operating clock frequency types, which are the main and peripheral clocks, the number of types will be H'02.)
- Minimum value of operating clock frequency (two bytes): The minimum value of the multiplied or divided clock frequency.

The minimum and maximum values of the operating clock frequency represent the values in MHz, valid to the hundredths place of MHz, and multiplied by 100. (e.g. when the value is 17.00 MHz, it will be 2000, which is H'07D0.)

- Maximum value (two bytes): Maximum value among the multiplied or divided clock frequencies.

There are as many pairs of minimum and maximum values as there are operating clock frequencies.

- SUM (one byte): Checksum

**(g) User Boot MAT Information Inquiry**

The boot program will return the number of user boot MATs and their addresses.

Command 

H'24
------

- Command, H'24, (one byte): Inquiry regarding user boot MAT information

Response	H'34	Size	Number of areas	
	Area-start address			Area-last address
	...			
	SUM			

- Response, H'34, (one byte): Response to user boot MAT information inquiry
- Size (one byte): The number of bytes that represents the number of areas, area-start addresses, and area-last address
- Number of Areas (one byte): The number of consecutive user boot MAT areas  
When user boot MAT areas are consecutive, the number of areas returned is H'01.
- Area-start address (four byte): Start address of the area
- Area-last address (four byte): Last address of the area  
There are as many groups of data representing the start and last addresses as there are areas.
- SUM (one byte): Checksum

**(h) User MAT Information Inquiry**

The boot program will return the number of user MATs and their addresses.

Command 

H'25
------

- Command, H'25, (one byte): Inquiry regarding user MAT information

Response	H'35	Size	Number of areas	
	Start address area			Last address area
	...			
	SUM			

- Response, H'35, (one byte): Response to the user MAT information inquiry
- Size (one byte): The number of bytes that represents the number of areas, area-start address and area-last address
- Number of areas (one byte): The number of consecutive user MAT areas  
When the user MAT areas are consecutive, the number of areas is H'01.
- Area-start address (four bytes): Start address of the area

- Area-last address (four bytes): Last address of the area  
There are as many groups of data representing the start and last addresses as there are areas.
- SUM (one byte): Checksum

### (i) Erased Block Information Inquiry

The boot program will return the number of erased blocks and their addresses.

Command 

H'26
------

- Command, H'26, (two bytes): Inquiry regarding erased block information

Response	H'36	Size	Number of blocks	
	Block start address			Block last address
	...			
	SUM			

- Response, H'36, (one byte): Response to the number of erased blocks and addresses
- Size (three bytes): The number of bytes that represents the number of blocks, block-start addresses, and block-last addresses.
- Number of blocks (one byte): The number of erased blocks
- Block start address (four bytes): Start address of a block
- Block last Address (four bytes): Last address of a block  
There are as many groups of data representing the start and last addresses as there are areas.
- SUM (one byte): Checksum

### (j) Programming Unit Inquiry

The boot program will return the programming unit used to program data.

Command 

H'27
------

- Command, H'27, (one byte): Inquiry regarding programming unit

Response	H'37	Size	Programming unit	SUM
----------	------	------	------------------	-----

- Response, H'37, (one byte): Response to programming unit inquiry
- Size (one byte): The number of bytes that indicate the programming unit, which is fixed to 2
- Programming unit (two bytes): A unit for programming  
This is the unit for reception of programming.
- SUM (one byte): Checksum

**(k) New Bit-Rate Selection**

The boot program will set a new bit rate and return the new bit rate.

This selection should be sent after sending the clock mode selection command.

Command	H'3F	Size	Bit rate	Input frequency
	Number of multiplication ratios	Multiplication ratio 1	Multiplication ratio 2	
	SUM			

- Command, H'3F, (one byte): Selection of new bit rate
- Size (one byte): The number of bytes that represents the bit rate, input frequency, number of multiplication ratios, and multiplication ratio
- Bit rate (two bytes): New bit rate  
One hundredth of the value (e.g. when the value is 19200 bps, it will be 192, which is H'00C0.)
- Input frequency (two bytes): Frequency of the clock input to the boot program  
This is valid to the hundredths place and represents the value in MHz multiplied by 100. (E.g. when the value is 20.00 MHz, it will be 2000, which is H'07D0.)
- Number of multiplication ratios (one byte): The number of multiplication ratios to which the device can be set.
- Multiplication ratio 1 (one byte): The value of multiplication or division ratios for the main operating frequency  
Multiplication ratio (one byte): The value of the multiplication ratio (e.g. when the clock frequency is multiplied by four, the multiplication ratio will be H'04.)  
Division ratio: The inverse of the division ratio, as a negative number (e.g. when the clock frequency is divided by two, the value of division ratio will be H'FE.  $H'FE = D^{-2}$ )
- Multiplication ratio 2 (one byte): The value of multiplication or division ratios for the peripheral frequency  
Multiplication ratio (one byte): The value of the multiplication ratio (e.g. when the clock frequency is multiplied by four, the multiplication ratio will be H'04.)  
(Division ratio: The inverse of the division ratio, as a negative number (E.g. when the clock is divided by two, the value of division ratio will be H'FE.  $H'FE = D^{-2}$ )
- SUM (one byte): Checksum

Response 

H'06
------

- Response, H'06, (one byte): Response to selection of a new bit rate  
When it is possible to set the bit rate, the response will be ACK.

Error Response 

H'BF	ERROR
------	-------

- Error response, H'BF, (one byte): Error response to selection of new bit rate
- ERROR: (one byte): Error code
  - H'11: Sum checking error
  - H'24: Bit-rate selection error  
The rate is not available.
  - H'25: Error in input frequency  
This input frequency is not within the specified range.
  - H'26: Multiplication-ratio error  
The ratio does not match an available ratio.
  - H'27: Operating frequency error  
The frequency is not within the specified range.

#### (4) Receive Data Check

The methods for checking of receive data are listed below.

##### 1. Input frequency

The received value of the input frequency is checked to ensure that it is within the range of minimum to maximum frequencies which matches the clock modes of the specified device. When the value is out of this range, an input-frequency error is generated.

##### 2. Multiplication ratio

The received value of the multiplication ratio or division ratio is checked to ensure that it matches the clock modes of the specified device. When the value is out of this range, an input-frequency error is generated.

##### 3. Operating frequency error

Operating frequency is calculated from the received value of the input frequency and the multiplication or division ratio. The input frequency is input to the LSI and the LSI is operated at the operating frequency. The expression is given below.

Operating frequency = Input frequency  $\times$  Multiplication ratio, or

Operating frequency = Input frequency  $\div$  Division ratio

The calculated operating frequency should be checked to ensure that it is within the range of minimum to maximum frequencies which are available with the clock modes of the specified device. When it is out of this range, an operating frequency error is generated.

#### 4. Bit rate

To facilitate error checking, the value (n) of clock select (CKS) in the serial mode register (SMR), and the value (N) in the bit rate register (BRR), which are found from the peripheral operating clock frequency ( $\phi$ ) and bit rate (B), are used to calculate the error rate to ensure that it is less than 4%. If the error is more than 4%, a bit rate error is generated. The error is calculated using the following expression:

$$\text{Error (\%)} = \left\{ \left[ \frac{\phi \times 10^6}{(N + 1) \times B \times 64 \times 2^{(2 \times n - 1)}} \right] - 1 \right\} \times 100$$

When the new bit rate is selectable, the rate will be set in the register after sending ACK in response. The host will send an ACK with the new bit rate for confirmation and the boot program will respond with that rate.

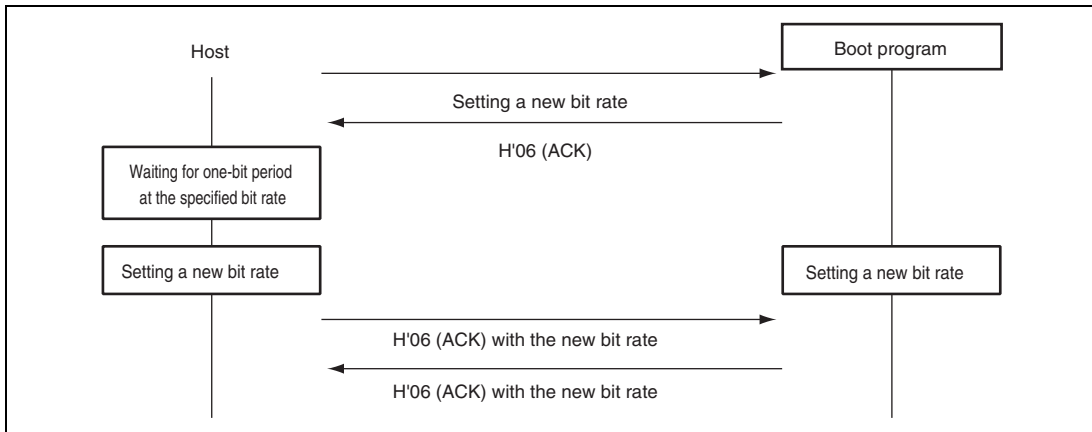

Confirmation H'06

- Confirmation, H'06, (one byte): Confirmation of a new bit rate

Response H'06

- Response, H'06, (one byte): Response to confirmation of a new bit rate

The sequence of new bit-rate selection is shown in figure 17.24.

**Figure 17.24 New Bit-Rate Selection Sequence**

## (5) Transition to Programming/Erasing State

The boot program will transfer the erasing program, and erase the user MATs and user boot MATs in that order. On completion of this erasure, ACK will be returned and will enter the programming/erasing state.

The host should select the device code, clock mode, and new bit rate with device selection, clock-mode selection, and new bit-rate selection commands, and then send the command for the transition to programming/erasing state. These procedures should be carried out before sending of the programming selection command or program data.

Command 

H'40
------

- Command, H'40, (one byte): Transition to programming/erasing state

Response 

H'06
------

- Response, H'06, (one byte): Response to transition to programming/erasing state  
The boot program will send ACK when the user MAT and user boot MAT have been erased by the transferred erasing program.

Error Response 

H'C0	H'51
------	------

- Error response, H'C0, (one byte): Error response for user boot MAT blank check
- Error code, H'51, (one byte): Erasing error  
An error occurred and erasure was not completed.

## (6) Command Error

A command error will occur when a command is undefined, the order of commands is incorrect, or a command is unacceptable. Issuing a clock-mode selection command before a device selection or an inquiry command after the transition to programming/erasing state command, are examples.

Error Response 

H'80	H'xx
------	------

- Error response, H'80, (one byte): Command error
- Command, H'xx, (one byte): Received command

## (7) Command Order

The order for commands in the inquiry selection state is shown below.

1. A supported device inquiry (H'20) should be made to inquire about the supported devices.
2. The device should be selected from among those described by the returned information and set with a device-selection (H'10) command.
3. A clock-mode inquiry (H'21) should be made to inquire about the supported clock modes.
4. The clock mode should be selected from among those described by the returned information and set.
5. After selection of the device and clock mode, inquiries for other required information should be made, such as the multiplication-ratio inquiry (H'22) or operating frequency inquiry (H'23), which are needed for a new bit-rate selection.
6. A new bit rate should be selected with the new bit-rate selection (H'3F) command, according to the returned information on multiplication ratios and operating frequencies.
7. After selection of the device and clock mode, the information of the user boot MAT and user MAT should be made to inquire about the user boot MATs information inquiry (H'24), user MATs information inquiry (H'25), erased block information inquiry (H'26), and programming unit inquiry (H'27).
8. After making inquiries and selecting a new bit rate, issue the transition to programming/erasing state command (H'40). The boot program will then enter the programming/erasing state.

## (8) Programming/Erasing State

A programming selection command makes the boot program select the programming method, a 128-byte programming command makes it program the memory with data, and an erasing selection command and block erasing command make it erase the block. Table 17.16 lists the programming/erasing commands.

**Table 17.16 Programming/Erasing Commands**

<b>Command</b>	<b>Command Name</b>	<b>Description</b>
H'42	User boot MAT programming selection	Transfers the user boot MAT programming program
H'43	User MAT programming selection	Transfers the user MAT programming program
H'50	128-byte programming	Programs 128 bytes of data
H'48	Erasing selection	Transfers the erasing program
H'58	Block erasing	Erases a block of data
H'52	Memory read	Reads the contents of memory
H'4A	User boot MAT sum check	Checks the checksum of the user boot MAT
H'4B	User MAT sum check	Checks the checksum of the user MAT
H'4C	User boot MAT blank check	Checks the blank data of the user boot MAT
H'4D	User MAT blank check	Checks the blank data of the user MAT
H'4F	Boot program status inquiry	Inquires into the boot program's status

- Programming

Programming is executed by the programming selection and 128-byte programming commands.

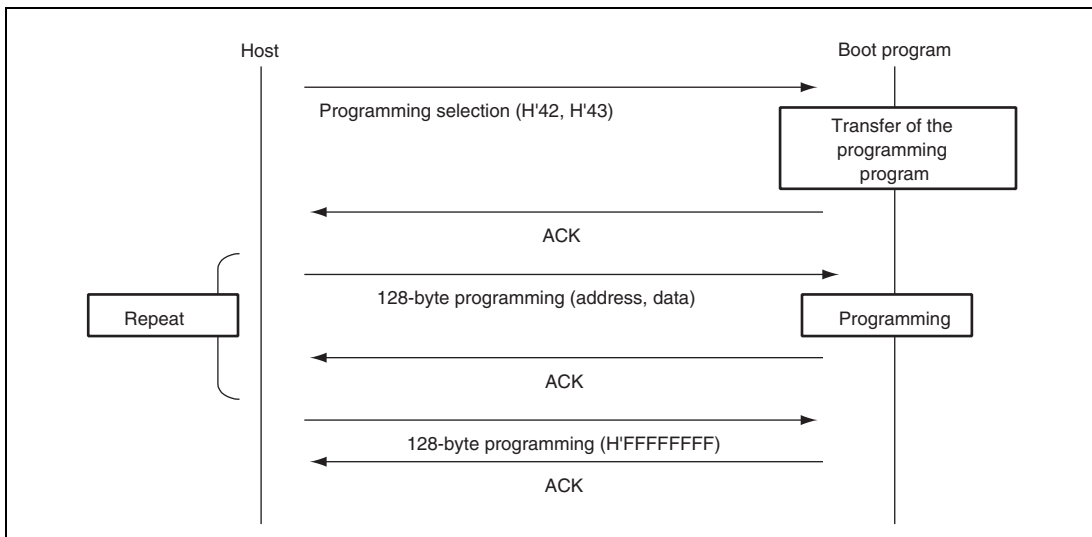

Firstly, the host should send the programming selection command and select the programming method and programming MATs. There are two programming selection commands, and selection is according to the area and method for programming.

1. User boot MAT programming selection
2. User MAT programming selection

After issuing the programming selection command, the host should send the 128-byte programming command. The 128-byte programming command that follows the selection command represents the data programmed according to the method specified by the selection command. When more than 128-byte data is programmed, 128-byte commands should repeatedly be executed. Sending a 128-byte programming command with H'FFFFFFF as the address will stop the programming. On completion of programming, the boot program will wait for selection of programming or erasing.

Where the sequence of programming operations that is executed includes programming with another method or of another MAT, the procedure must be repeated from the programming selection command.

The sequence for the programming selection and 128-byte programming commands is shown in figure 17.25.

**Figure 17.25 Programming Sequence**

- Erasure

Erasure is executed by the erasure selection and block erasure commands.

Firstly, erasure is selected by the erasure selection command and the boot program then erases the specified block. The command should be repeatedly executed if two or more blocks are to be erased. Sending a block erasure command from the host with the block number H'FF will stop the erasure operating. On completion of erasing, the boot program will wait for selection of programming or erasing.

The sequence for the erasure selection and block erasure commands is shown in figure 17.26.

**Figure 17.26 Erasure Sequence**

**(a) User Boot MAT Programming Selection**

The boot program will transfer a programming program. The data is programmed to the user boot MATs by the transferred programming program.

Command 

H'42
------

- Command, H'42, (one byte): User boot-program programming selection

Response 

H'06
------

- Response, H'06, (one byte): Response to user boot-program programming selection  
When the programming program has been transferred, the boot program will return ACK.

Error Response 

H'C2	ERROR
------	-------

- Error response : H'C2 (1 byte): Error response to user boot MAT programming selection
- ERROR : (1 byte): Error code  
H'54: Selection processing error (transfer error occurs and processing is not completed)

**(b) User MAT Programming Selection**

The boot program will transfer a program for user MAT programming selection. The data is programmed to the user MATs by the transferred program for programming.

Command 

H'43
------

- Command, H'43, (one byte): User-program programming selection

Response 

H'06
------

- Response, H'06, (one byte): Response to user-program programming selection  
When the programming program has been transferred, the boot program will return ACK.

Error Response 

H'C3	ERROR
------	-------

- Error response : H'C3 (1 byte): Error response to user boot MAT programming selection
- ERROR : (1 byte): Error code  
H'54: Selection processing error (transfer error occurs and processing is not completed)

**(c) 128-Byte Programming**

The boot program will use the programming program transferred by the programming selection to program the user boot MATs or user MATs in response to 128-byte programming.

Command	H'50	Address							
	Data	...							
	...								
	SUM								

- Command, H'50, (one byte): 128-byte programming
- Programming Address (four bytes): Start address for programming  
Multiple of the size specified in response to the programming unit inquiry (i.e. H'00, H'01, H'00, H'00 : H'00010000)
- Program data (128 bytes): Data to be programmed  
The size is specified in the response to the programming unit inquiry.
- SUM (one byte): Checksum

Response 

H'06
------

- Response, H'06, (one byte): Response to 128-byte programming  
On completion of programming, the boot program will return ACK.

Error Response 

H'D0	ERROR
------	-------

- Error response, H'D0, (one byte): Error response for 128-byte programming
- ERROR: (one byte): Error code
  - H'11: Checksum Error
  - H'2A: Address error  
The address is not in the MAT.
  - H'53: Programming error  
A programming error has occurred and programming cannot be continued.

The specified address should match the unit for programming of data. For example, when the programming is in 128-byte units, the lower eight bits of the address should be H'00 or H'80. When there are less than 128 bytes of data to be programmed, the host should fill the rest with H'FF.

Sending the 128-byte programming command with the address of H'FFFFFFFF will stop the programming operation. The boot program will interpret this as the end of the programming and wait for selection of programming or erasing.

Command 

H'50	Address	SUM
------	---------	-----

- Command, H'50, (one byte): 128-byte programming
- Programming Address (four bytes): End code is H'FF, H'FF, H'FF, H'FF.
- SUM (one byte): Checksum

Response 

H'06
------

- Response, H'06, (one byte): Response to 128-byte programming  
On completion of programming, the boot program will return ACK.

Error Response 

H'D0	ERROR
------	-------

- Error Response, H'D0, (one byte): Error response for 128-byte programming
- ERROR: (one byte): Error code
  - H'11: Checksum error
  - H'53: Programming errorAn error has occurred in programming and programming cannot be continued.

#### (d) Erasure Selection

The boot program will transfer the erasure program. User MAT data is erased by the transferred erasure program.

Command 

H'48
------

- Command, H'48, (one byte): Erasure selection

Response 

H'06
------

- Response, H'06, (one byte): Response for erasure selection  
After the erasure program has been transferred, the boot program will return ACK.

Error Response 

H'C8	ERROR
------	-------

- Error Response, H'C8, (one byte): Error response to erasure selection
- ERROR: (one byte): Error code
  - H'54: Selection processing error (transfer error occurs and processing is not completed)

**(e) Block Erasure**

The boot program will erase the contents of the specified block.

Command	H'58	Size	Block number	SUM
---------	------	------	--------------	-----

- Command, H'58, (one byte): Erasure
- Size (one byte): The number of bytes that represents the erase block number  
This is fixed to 1.
- Block number (one byte): Number of the block to be erased
- SUM (one byte): Checksum

Response	H'06
----------	------

- Response, H'06, (one byte): Response to Erasure  
After erasure has been completed, the boot program will return ACK.

Error Response	H'D8	ERROR
----------------	------	-------

- Error Response, H'D8, (one byte): Response to Erasure
- ERROR (one byte): Error code
  - H'11: Sum check error
  - H'29: Block number error  
Block number is incorrect.
  - H'51: Erasure error  
An error has occurred during erasure.

On receiving block number H'FF, the boot program will stop erasure and wait for a selection command.

Command	H'58	Size	Block number	SUM
---------	------	------	--------------	-----

- Command, H'58, (one byte): Erasure
- Size, (one byte): The number of bytes that represents the block number  
This is fixed to 1.
- Block number (one byte): H'FF  
Stop code for erasure
- SUM (one byte): Checksum

Response	H'06
----------	------

- Response, H'06, (one byte): Response to end of erasure (ACK)  
When erasure is to be performed after the block number H'FF has been sent, the procedure should be executed from the erasure selection command.

**(f) Memory Read**

The boot program will return the data in the specified address.

Command	H'52	Size	Area	Read address		
	Read size			SUM		

- Command: H'52 (1 byte): Memory read
- Size (1 byte): Amount of data that represents the area, read address, and read size (fixed at 9)
- Area (1 byte)

H'00: User boot MAT

H'01: User MAT

An address error occurs when the area setting is incorrect.

- Read address (4 bytes): Start address to be read from
- Read size (4 bytes): Size of data to be read
- SUM (1 byte): Checksum

Response	H'52	Read size							
	Data	...							
	SUM								

- Response: H'52 (1 byte): Response to memory read
- Read size (4 bytes): Size of data to be read
- Data (n bytes): Data for the read size from the read address
- SUM (1 byte): Checksum

Error Response	H'D2	ERROR
----------------	------	-------

- Error response: H'D2 (1 byte): Error response to memory read
- ERROR: (1 byte): Error code

H'11: Sum check error

H'2A: Address error

The read address is not in the MAT.

H'2B: Size error

The read size exceeds the MAT.

**(g) User-Boot Program Sum Check**

The boot program will return the byte-by-byte total of the contents of the bytes of the user-boot program, as a four-byte value.

Command 

H'4A
------

- Command, H'4A, (one byte): Sum check for user-boot program

Response 

H'5A	Size	Checksum of user boot program	SUM
------	------	-------------------------------	-----

- Response, H'5A, (one byte): Response to the sum check of user-boot program
- Size (one byte): The number of bytes that represents the checksum  
This is fixed to 4.
- Checksum of user boot program (four bytes): Checksum of user boot MATs  
The total of the data is obtained in byte units.
- SUM (one byte): Sum check for data being transmitted

**(h) User-Program Sum Check**

The boot program will return the byte-by-byte total of the contents of the bytes of the user program.

Command 

H'4B
------

- Command, H'4B, (one byte): Sum check for user program

Response 

H'5B	Size	Checksum of user program	SUM
------	------	--------------------------	-----

- Response, H'5B, (one byte): Response to the sum check of the user program
- Size (one byte): The number of bytes that represents the checksum  
This is fixed to 4.
- Checksum of user boot program (four bytes): Checksum of user MATs  
The total of the data is obtained in byte units.
- SUM (one byte): Sum check for data being transmitted

**(i) User Boot MAT Blank Check**

The boot program will check whether or not all user boot MATs are blank and return the result.

Command 

H'4C
------

- Command, H'4C, (one byte): Blank check for user boot MAT

Response 

H'06
------

- Response, H'06, (one byte): Response to the blank check of user boot MAT  
If all user MATs are blank (H'FF), the boot program will return ACK.

Error Response 

H'CC	H'52
------	------

- Error Response, H'CC, (one byte): Response to blank check for user boot MAT
- Error Code, H'52, (one byte): Erasure has not been completed.

### (j) User MAT Blank Check

The boot program will check whether or not all user MATs are blank and return the result.

Command 

H'4D
------

- Command, H'4D, (one byte): Blank check for user MATs

Response 

H'06
------

- Response, H'06, (one byte): Response to the blank check for user MATs  
If the contents of all user MATs are blank (H'FF), the boot program will return ACK.

Error Response 

H'CD	H'52
------	------

- Error Response, H'CD, (one byte): Error response to the blank check of user MATs.
- Error code, H'52, (one byte): Erasure has not been completed.

### (k) Boot Program State Inquiry

The boot program will return indications of its present state and error condition. This inquiry can be made in the inquiry/selection state or the programming/erasing state.

Command 

H'4F
------

- Command, H'4F, (one byte): Inquiry regarding boot program's state

Response 

H'5F	Size	Status	ERROR	SUM
------	------	--------	-------	-----

- Response, H'5F, (one byte): Response to boot program state inquiry
- Size (one byte): The number of bytes. This is fixed to 2.
- Status (one byte): State of the boot program
- ERROR (one byte): Error status  
ERROR = 0 indicates normal operation.  
ERROR = 1 indicates error has occurred.

- SUM (one byte): Sum check

**Table 17.17 Status Code**

<b>Code</b>	<b>Description</b>
H'11	Device selection wait
H'12	Clock mode selection wait
H'13	Bit rate selection wait
H'1F	Programming/erasing state transition wait (bit rate selection is completed)
H'31	Programming state for erasure
H'3F	Programming/erasing selection wait (erasure is completed)
H'4F	Program data receive wait
H'5F	Erase block specification wait (erasure is completed)

**Table 17.18 Error Code**

<b>Code</b>	<b>Description</b>
H'00	No error
H'11	Sum check error
H'12	Program size error
H'21	Device code mismatch error
H'22	Clock mode mismatch error
H'24	Bit rate selection error
H'25	Input frequency error
H'26	Multiplication ratio error
H'27	Operating frequency error
H'29	Block number error
H'2A	Address error
H'2B	Data length error
H'51	Erase error
H'52	Erase incomplete error
H'53	Programming error
H'54	Selection processing error
H'80	Command error
H'FF	Bit-rate-adjustment confirmation error

## 17.14 Usage Notes

1. The initial state of the product at its shipment is in the erased state. For the product whose revision of erasing is undefined, we recommend to execute automatic erasure for checking the initial state (erased state) and compensating.
2. For the PROM programmer suitable for programmer mode in this LSI and its program version, refer to the instruction manual of the socket adapter.
3. If the socket, socket adapter, or product index does not match the specifications, too much current flows and the product may be damaged.
4. Use a PROM programmer that supports the device with 256-kbyte on-chip flash memory and 5.0-V programming voltage. Do not select HN28F101 and 3.3-V programming voltage with the programmer parameters. Use only the specified socket adapter.
5. Do not remove the chip from the PROM programmer nor input a reset signal during programming/erasing in which a high voltage is applied to the flash memory. Doing so may damage the flash memory permanently. If a reset is input accidentally, the reset must be released after the reset input period of at least 100  $\mu$ s.
6. The flash memory is not accessible until FKEY is cleared after programming/erasing starts. If the operating mode is changed and this LSI is restarted by a reset immediately after programming/erasing has finished, secure the reset input period (period of  $\overline{\text{RES}} = 0$ ) of at least 100  $\mu$ s. Transition to the reset state during programming/erasing is inhibited. If a reset is input accidentally, the reset must be released after the reset input period of at least 100  $\mu$ s.
7. At powering on or off the Vcc power supply, fix the  $\overline{\text{RES}}$  pin to low and set the flash memory to hardware protection state. This power on/off timing must also be satisfied at a power-off and power-on caused by a power failure and other factors.
8. In on-board programming mode or programmer mode, programming of the 128-byte programming-unit block must be performed only once. Perform programming in the state where the programming-unit block is fully erased.
9. When the chip is to be reprogrammed with the programmer after execution of programming or erasure in on-board programming mode, it is recommended that automatic programming is performed after execution of automatic erasure.
10. To program the flash memory, the program data and program must be placed at higher addresses than those of the external interrupt vector table, and H'FF must be written to all the system reserved areas in the exception handling vector table.

11. The programming program that includes the initialization routine and the erasing program that includes the initialization routine are each 4 kbytes or less. Accordingly, when the CPU clock frequency is 48 MHz, the download for each program takes approximately 35  $\mu$ s at the maximum.
12. A programming/erasing program for the flash memory used in a conventional F-ZTAT H8, H8S microcomputer which does not support download of the on-chip program by setting the SCO bit in FCCS to 1 cannot run in this LSI. Be sure to download the on-chip program to execute programming/erasing of the flash memory in this F-ZTAT H8SX microcomputer.
- 13 Unlike a conventional F-ZTAT H8 or H8S microcomputers, measures against a program crash are not taken by WDT during programming/erasing. When needed, measures should be taken by user. A periodic interrupt generated by the WDT can be used as the measures, as an example. The interrupt generation cycle should take into consideration time to download a programming/erasing program and time to program/erase the flash memory.
- 14 When downloading the programming/erasing program, do not clear the SCO bit in FCCS to 0 after immediately setting it to 1. Otherwise, download cannot be performed normally. Immediately after executing the instruction to set the SCO bit to 1, dummy read of the FCCS must be executed twice.
15. The contents of some general registers are not saved in a programming/erasing program. When needed, save general registers in the procedure program.
16. The intervals for executing the user branch processing differ in programming and erasing. The processing phase also differs. Table 17.19 lists the maximum and minimum intervals for initiating the user branch processing when the CPU clock frequency is 40/48 MHz.

**Table 17.19 Initiation Intervals of User Branch Processing**

<b>Processing Name</b>	<b>Maximum Interval</b>	<b>Minimum Interval</b>
Programming	Approximately 1 ms	Approximately 19 $\mu$ s
Erasing	Approximately 5 ms	Approximately 19 $\mu$ s

17. While an instruction in on-chip RAM is being executed, the DMAC can write to the SCO bit in FCCS that is used for a download request or FMATS that is used for MAT switching. Make sure that these registers are not accidentally written to, otherwise an on-chip program may be downloaded and damage RAM or a MAT switchover may occur and the CPU get out of control.

## 18. States in which NMI Interrupt is Ignored

In the following modes or period, the NMI interrupt requests are ignored; they are not executed and the interrupt sources are not retained.

- Boot mode
- Programmer mode
- Checking the flash memory-related registers immediately after user boot mode is initiated (Approximately a period of A (s) if operation is done at an input clock frequency of B (Hz) after the reset signal is released)

$$A = \frac{1}{B \times 2} \times 1200$$

The following is an example when an input clock frequency is 5 MHz.

$$\frac{1}{5 \times 10^6 \times 2} \times 1200 = 120 \times 10^{-6} = 120 \mu\text{s}$$

## 19. Notes on NMI Interrupt During Programming/Erasing

Do not execute interrupt processing during programming/erasing. Doing so causes the error protection state to be entered, aborts programming/erasing, and prevents flash memory from being successfully programmed/erased.

When executing an NMI interrupt during programming/erasing for error processing, the following should be noted.

- The NMI interrupt is an only interrupt that can be used during programming/erasing.
- When flash memory is being programmed or erased, both the user MAT and user boot MAT cannot be accessed. Prepare the interrupt vector table and interrupt processing routine in on-chip RAM by setting VBR. Make sure the flash memory being programmed or erased is not accessed by the interrupt processing routine. If flash memory is read, the read values are not guaranteed.
- Since generation of NMI requests (or other interrupt requests) during programming/erasing causes the error protection state to be entered, programming or erasing is aborted. For details on the error protection, see section 17.9.3, Error Protection.

## 20. Notes on Returning From the Error Protection State

Allow a reset period of 100  $\mu$ s or longer before releasing the reset signal to return from the error protection state. A transition to the error protection state aborts programming or erasing, and programming or erasing is not performed properly. Note the following when returning from the error protection state to each mode.

### — Boot mode

The boot program programmed in the LSI is initiated when the reset signal is released. All of the user MAT and user boot MAT are automatically erased before programming.

### — User boot mode

The embedded check routine that is programmed in the LSI runs when the reset signal is released. Then, processing starts from the execution start address of the reset vector in the user boot MAT. First, erase all of the user MAT. Since data in the flash memory may be damaged, do not start with partial erasure or programming.

### — User program mode

The program programmed in the user MAT is initiated when the reset signal is released. However, the program may not be initiated properly from the user MAT after releasing the reset signal. Erase all of the user MAT in boot mode etc. before programming. Then, set to user program mode before releasing the reset signal again.

## Section 18 Clock Pulse Generator

This LSI has an on-chip clock pulse generator (CPG) that generates the system clock ( $I\phi$ ), peripheral module clock ( $P\phi$ ), and external clock ( $B\phi$ ).

The clock pulse generator consists of an oscillator, PLL (Phase Locked Loop) circuit, and divider. Figure 18.1 shows a block diagram of the clock pulse generator.

Clock frequencies can be changed by the PLL circuit and divider in the CPG. Changing the system clock control register (SCKCR) setting by software can change the clock frequencies.

This LSI supports three types of clocks: a system clock provided to the CPU and bus masters, a peripheral module clock provided to the peripheral modules, and an external clock provided to the external bus. These clocks can be specified independently. Note, however, that the frequencies of the peripheral clock and external clock are lower than that of the system clock.

**Figure 18.1** Block Diagram of Clock Pulse Generator

## 18.1 Register Description

The clock pulse generator has the following register.

- System clock control register (SCKCR)

### 18.1.1 System Clock Control Register (SCKCR)

SCKCR controls B $\phi$  clock output and frequencies of the system, peripheral module, and external clocks, and selects the B $\phi$  clock to be output.

Bit	15	14	13	12	11	10	9	8
Bit Name	PSTOP1	—	POSEL1	—	—	ICK2	ICK1	ICK0
Initial Value	0	0	0	0	0	0	1	0

0	BCK0	0	R/W		

## [Legend]

X: Don't care

## 18.2 Oscillator

Clock pulses can be supplied by connecting a crystal resonator, or by input of an external clock.

### 18.2.1 Connecting Crystal Resonator

A crystal resonator can be connected as shown in the example in figure 18.2. Select the damping resistance  $R_d$  according to table 18.1. An AT-cut parallel-resonance type should be used.

When the clock is provided by connecting a crystal resonator, a crystal resonator having a frequency of 4 to 9 MHz should be connected.

**Figure 18.2 Connection of Crystal Resonator (Example)**

**Table 18.1 Damping Resistance Value**

Frequency (MHz)	4	6	8	9
$R_d$ ( $\Omega$ )	500	300	200	100

Figure 18.3 shows an equivalent circuit of the crystal resonator. Use a crystal resonator that has the characteristics shown in table 18.2.

**Figure 18.3 Crystal Resonator Equivalent Circuit**

**Table 18.2 Crystal Resonator Characteristics**

Frequency (MHz)	4	6	8	9
$R_s$ Max. ( $\Omega$ )	120	100	80	80
$C_0$ Max. (pF)	7	7	7	7

### 18.2.2 External Clock Input

An external clock signal can be input as shown in the examples in figure 18.4. If the XTAL pin is left open, make sure that parasitic capacitance is no more than 10 pF. When the counter clock is input to the XTAL pin, make sure that the external clock is held high in standby mode.

**Figure 18.4 External Clock Input (Examples)**

For the input conditions of the external clock, refer to table 21.4, Clock Timing, in section 21.3.1, Clock Timing. The input external clock should be from 4 to 9 MHz.

## 18.3 PLL Circuit

The PLL circuit has the function of multiplying the frequency of the clock from the oscillator by a factor of 8. The frequency multiplication factor is fixed.

## 18.4 Frequency Divider

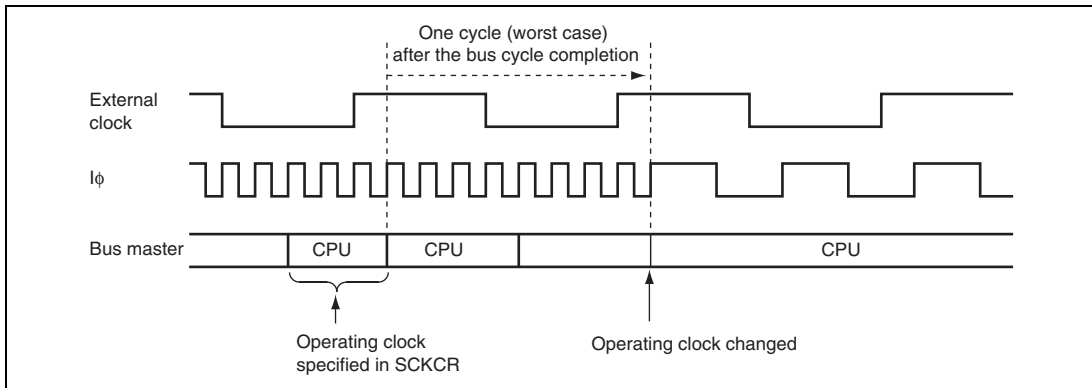

The frequency divider divides the PLL clock to generate a 1/2, 1/4, or 1/8 clock. After bits ICK2 to ICK0 and PCK 2 to PCK0 are modified, this LSI operates at the modified frequency.

## 18.5 Usage Notes

### 18.5.1 Notes on Clock Pulse Generator

1. The following points should be noted since the frequency of  $\phi$  ( $I\phi$ : system clock and  $P\phi$ : peripheral module clock) supplied to each module changes according to the setting of SCKCR. Select a clock division ratio that is within the operation guaranteed range of clock cycle time  $t_{\text{cyc}}$  shown in the AC timing of electrical characteristics as follows.
  - When the SSU is in use  
Ensure the following settings:  
 $I\phi$  (min.) = 8 MHz,  $P\phi$  (min.) = 8 MHz,  $I\phi$  (max.) = 48 MHz, and  $P\phi$  (max.) = 24 MHz.  
The following settings are not permitted:  
 $I\phi < 8$  MHz,  $I\phi > 48$  MHz,  $P\phi < 8$  MHz, and  $P\phi > 24$  MHz.
  - When the SSU is not in use  
Ensure the following settings:  
 $I\phi$  (min.) = 8 MHz,  $P\phi$  (min.) = 8 MHz,  $I\phi$  (max.) = 48 MHz, and  $P\phi$  (max.) = 35 MHz.  
The following settings are not permitted:  
 $I\phi < 8$  MHz,  $I\phi > 48$  MHz,  $P\phi < 8$  MHz, and  $P\phi > 35$  MHz.
2. All the on-chip peripheral modules (except for the DMAC) operate on the  $P\phi$ . Therefore, note that the time processing of modules such as a timer and SCI differs before and after changing the clock division ratio.  
  
In addition, wait time for clearing software standby mode differs by changing the clock division ratio. For details, see section 19.7.3, Setting Oscillation Settling Time after Clearing Software Standby Mode.
3. The relationship between the system clock and peripheral module clock is  $I\phi \geq P\phi$ . In addition, the system clock setting has priority. Accordingly,  $P\phi$  may have the frequency set by bits ICK2 to ICK0 regardless of the settings of bits PCK2 to PCK0.
4. Figure 18.5 shows the clock modification timing. After a value is written to SCKCR, this LSI waits for the current bus cycle to complete. After the current bus cycle completes, each clock frequency will be modified within one cycle (worst case) of the external clock.

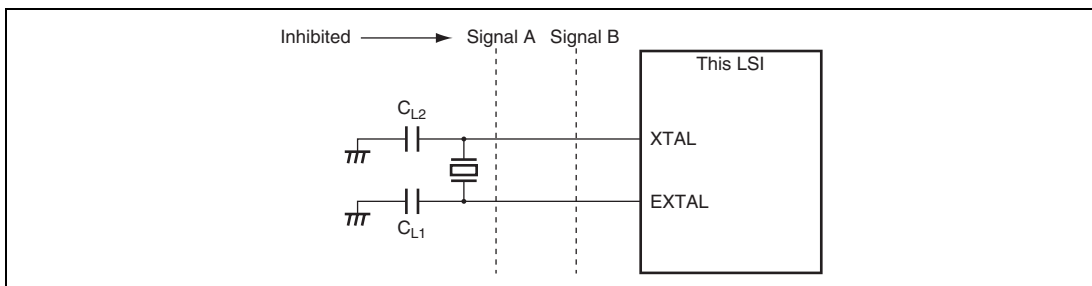

**Figure 18.5 Clock Modification Timing**

### 18.5.2 Notes on Resonator

Since various characteristics related to the resonator are closely linked to the user's board design, thorough evaluation is necessary on the user's part, using the resonator connection examples shown in this section as a reference. As the parameters for the resonator will depend on the floating capacitance of the resonator and the mounting circuit, the parameters should be determined in consultation with the resonator manufacturer. The design must ensure that a voltage exceeding the maximum rating is not applied to the resonator pin.

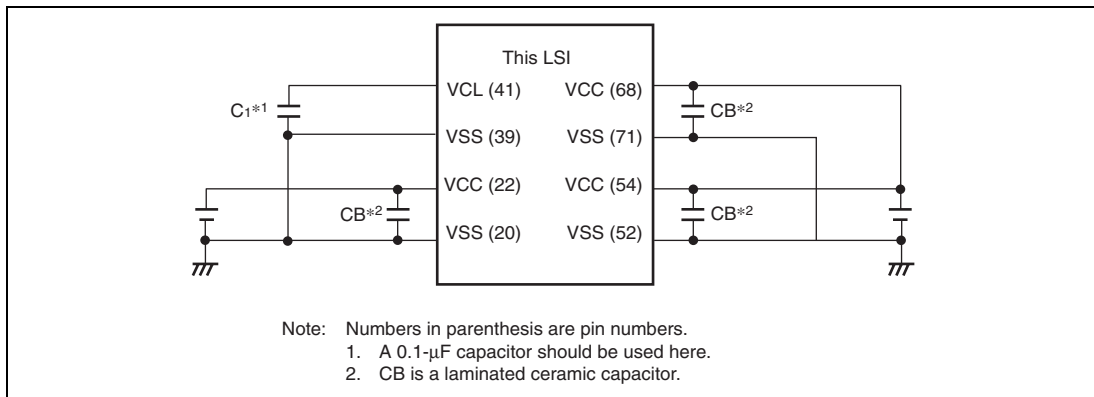

### 18.5.3 Notes on Board Design

When using the crystal resonator, place the crystal resonator and its load capacitors as close as possible to the XTAL and EXTAL pins. Other signal lines should be routed away from the oscillation circuit as shown in figure 18.6 to prevent induction from interfering with correct oscillation.

**Figure 18.6 Note on Board Design for Oscillation Circuit**

Figure 18.7 shows a connection example of bypass capacitor. Please be sure to insert bypass capacitor (CB) close to the Vcc and Vss pins and its capacitance meets the characteristics of the user system board.

**Figure 18.7 Connection Example of Bypass Capacitor**

#### 18.5.4 Notes on Input Clock Frequency

The frequency of the input clock is multiplied in the PLL circuit by a factor of 8. To reduce noises, a lower frequency ranging of 4 to 9 MHz is recommended.

## Section 19 Power-Down Modes

This LSI has power consumption reduction functions, such as multi-clock function, module stop function, and transition function to power-down mode.

### 19.1 Features

- Multi-clock function  
The frequency division ratio is settable independently for the system clock, peripheral module clock, and external bus clock.
- Module stop function  
The functions for each peripheral modules can be stopped to make a transition to a power-down mode.
- Transition function to power-down mode  
Transition to a power-down mode is possible to stop the CPU, all the on-chip peripheral modules, and oscillator.
- Three power-down modes  
Sleep mode  
All-module-clock-stop mode  
Software standby mode

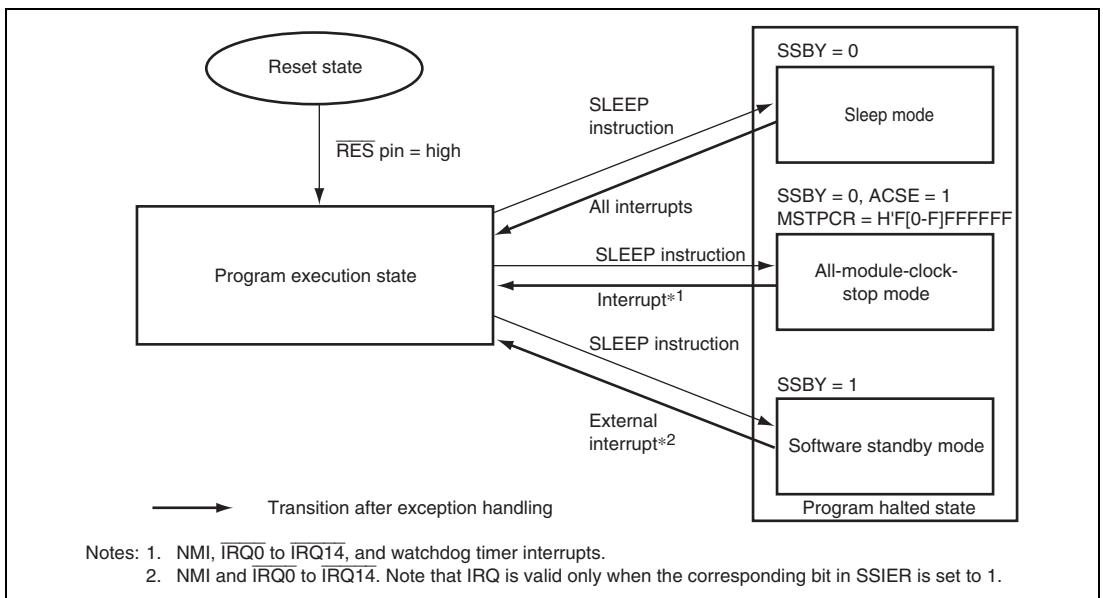

Table 19.1 shows conditions for making a transition to a power-down mode, states of the CPU and peripheral modules, and clearing method for each mode. After the reset state, since this LSI operates in normal program execution state, the modules, other than the DMAC are stopped.

**Table 19.1 Operating States**

Operating State	Sleep Mode	All-Module-Clock-Stop Mode	Software Standby Mode
Transition condition	Control register + instruction	Control register + instruction	Control register + instruction
Cancellation method	Interrupt	Interrupt* <sup>2</sup>	External interrupt
Oscillator	Functions	Functions	Halted
CPU	Halted (retained)	Halted (retained)	Halted (retained)
Watchdog timer	Functions	Functions	Halted (retained)
Other peripheral modules	Functions	Halted* <sup>3</sup>	Halted* <sup>1</sup>
I/O port	Functions	Retained	Retained

Notes: "Halted (retained)" in the table means that the internal register values are retained and internal operations are suspended.

1. SCI, RCAN-ET, and SSU enter the reset state, and other peripheral modules retain their states.
2. External interrupt and some internal interrupts (watchdog timer)
3. RCAN-ET and SSU enter the reset state, and other peripheral modules retain their states.

**Figure 19.1 Mode Transitions**

## 19.2 Register Descriptions

The registers related to the power-down modes are shown below. For details on the system clock control register (SCKCR), refer to section 18.1.1, System Clock Control Register (SCKCR).

- Standby control register (SBYCR)
- Module stop control register A (MSTPCRA)
- Module stop control register B (MSTPCRB)
- Module stop control register C (MSTPCRC)

### 19.2.1 Standby Control Register (SBYCR)

SBYCR controls software standby mode.

Bit	15	14	13	12	11	10	9	8
Bit Name	SSBY	—	—	STS4	STS3	STS2	STS1	STS0
Initial Value	0	1	0	0	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	7	6	5	4	3	2	1	0
Bit Name	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	SSBY	0	R/W	<p>Software Standby</p> <p>Specifies the transition mode after executing the SLEEP instruction</p> <p>0: Shifts to sleep mode after the SLEEP instruction is executed</p> <p>1: Shifts to software standby mode after the SLEEP instruction is executed</p> <p>This bit does not change when clearing the software standby mode by using external interrupts and shifting to normal operation. For clearing, write 0 to this bit. When the WDT is used as the watchdog timer, the setting of this bit is disabled. In this case, a transition is always made to sleep mode or all-module-clock-stop mode after the SLEEP instruction is executed.</p>

Bit	Bit Name	Initial Value	R/W	Description
14	—	1	R/W	Reserved This bit is always read as 1. The write value should always be 1.
13	—	0	R/W	Reserved This bit is always read as 0. The write value should always be 0.
12	STS4	0	R/W	Standby Timer Select 4 to 0
11	STS3	1	R/W	These bits select the time the MCU waits for the clock to settle when software standby mode is cleared by an external interrupt. With a crystal resonator, refer to table 19.2 and make a selection according to the operating frequency so that the standby time is at least equal to the oscillation settling time. With an external clock, a PLL circuit settling time is necessary. Refer to table 19.2 to set the standby time. While oscillation is being settled, the timer is counted on the P $\phi$ clock frequency. Careful consideration is required in multi-clock mode. 00000: Reserved 00001: Reserved 00010: Reserved 00011: Reserved 00100: Reserved 00101: Standby time = 64 states 00110: Standby time = 512 states 00111: Standby time = 1024 states 01000: Standby time = 2048 states 01001: Standby time = 4096 states 01010: Standby time = 16384 states 01011: Standby time = 32768 states 01100: Standby time = 65536 states 01101: Standby time = 131072 states 01110: Standby time = 262144 states 01111: Standby time = 524288 states 10000: Reserved 10001: Reserved 1001X: Reserved 101XX: Reserved 11XXX: Reserved
10	STS2	1	R/W	
9	STS1	1	R/W	
8	STS0	1	R/W	

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.

Note: The flash memory settling time must be reserved.

### 19.2.2 Module Stop Control Registers A and B (MSTPCRA and MSTPCRB)

MSTPCRA and MSTPCRB control module stop mode. Setting a bit to 1 makes the corresponding module enter module stop mode, while clearing the bit to 0 clears module stop mode.

#### • MSTPCRA

Bit	15	14	13	12	11	10	9	8
Bit Name	ACSE	MSTPA14	MSTPA13	MSTPA12	MSTPA11	MSTPA10	MSTPA9	MSTPA8
Initial Value	0	0	0	0	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	7	6	5	4	3	2	1	0
Bit Name	MSTPA7	MSTPA6	MSTPA5	MSTPA4	MSTPA3	MSTPA2	MSTPA1	MSTPA0
Initial Value	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

#### • MSTPCRB

Bit	15	14	13	12	11	10	9	8
Bit Name	MSTPB15	MSTPB14	MSTPB13	MSTPB12	MSTPB11	MSTPB10	MSTPB9	MSTPB8
Initial Value	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

3	MSTPA3	1	R/W	A/D converter (unit 0)
2	MSTPA2	1	R/W	Reserved These bits are always read as 1. The write value should always be 1.
1	MSTPA1	1	R/W	16-bit timer pulse unit (TPU channels 11 to 6)
0	MSTPA0	1	R/W	16-bit timer pulse unit (TPU channels 5 to 0)*

Note: \* Supported only by the H8SX/1527R.

- MSTPCRB

Bit	Bit Name	Initial Value	R/W	Module
15	MSTPB15	1	R/W	Programmable pulse generator (PPG)*
14	MSTPB14	1	R/W	Reserved
13	MSTPB13	1	R/W	These bits are always read as 1. The write value should always be 1.
12	MSTPB12	1	R/W	Serial communication interface_4 (SCI_4)
11	MSTPB11	1	R/W	Serial communication interface_3 (SCI_3)
10	MSTPB10	1	R/W	Reserved
9	MSTPB9	1	R/W	These bits are always read as 1. The write value should always be 1.
8	MSTPB	1	R/W	
7	MSTPB7	1	R/W	
6	MSTPB6	1	R/W	
5	MSTPB5	1	R/W	
4	MSTPB4	1	R/W	
3	MSTPB3	1	R/W	
2	MSTPB2	1	R/W	
1	MSTPB1	1	R/W	
0	MSTPB0	1	R/W	

Note: \* Supported only by the H8SX/1527R.

### 19.2.3 Module Stop Control Register C (MSTPCRC)

When bits MSTPC1 and MSTPC0 are set to 1, the corresponding on-chip RAM stops. Do not set the corresponding MSTPC1 and MSTPC0 bits to 1 while accessing the on-chip RAM.

Bit	15	14	13	12	11	10	9	8
Bit Name	MSTPC15	MSTPC14	MSTPC13	MSTPC12	MSTPC11	MSTPC10	MSTPC9	MSTPC8
Initial Value	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	7	6	5	4	3	2	1	0
Bit Name	MSTPC7	MSTPC6	MSTPC5	MSTPC4	MSTPC3	MSTPC2	MSTPC1	MSTPC0
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Module
15	MSTPC15	1	R/W	Reserved
14	MSTPC14	1	R/W	These bits are always read as 1. The write value should always be 1.
13	MSTPC13	1	R/W	
12	MSTPC12	1	R/W	
11	MSTPC11	1	R/W	Controller area network (RCAN-ET)
10	MSTPC10	1	R/W	Synchronous serial communication unit 2 (SSU_2)
9	MSTPC9	1	R/W	Synchronous serial communication unit 1 (SSU_1)
8	MSTPC8	1	R/W	Synchronous serial communication unit 0 (SSU_0)
7	MSTPC7	0	R/W	Reserved
6	MSTPC6	0	R/W	These bits are always read as 0. The write value should always be 0.
5	MSTPC5	0	R/W	
4	MSTPC4	0	R/W	
3	MSTPC3	0	R/W	
2	MSTPC2	0	R/W	
1	MSTPC1	0	R/W	On-chip RAM (H'FFF9000 to H'FFFBFFF)
0	MSTPC0	0	R/W	The write value to MSTPC1 and MSTPC0 should always be the same.

## 19.3 Multi-Clock Function

When bits ICK2 to ICK0, PCK2 to PCK0, and BCK2 to BCK0 in SCKCR are set, a transition is made to multi-clock mode at the end of the bus cycle. In multi-clock mode, the CPU and bus masters operate on the operating clock specified by bits ICK2 to ICK0. The peripheral modules operate on the operating clock specified by bits PCK2 to PCK0. The external bus operates on the operating clock specified by bits BCK2 to BCK0.

Even if the frequencies specified by bits PCK2 to PCK0 and BCK2 to BCK0 are higher than the frequency specified by bits ICK2 to ICK0, the specified values are not reflected in the peripheral module and external bus clocks. The peripheral module and external bus clocks are restricted to the operating clock specified by bits ICK2 to ICK0.

Multi-clock mode is cleared by clearing all of bits ICK2 to ICK0, PCK2 to PCK0, and BCK2 to BCK0 to 0. A transition is made to normal mode at the end of the bus cycle, and multi-clock mode is cleared.

If a SLEEP instruction is executed while the SSBY bit in SBYCR is cleared to 0, this LSI enters sleep mode. When sleep mode is cleared by an interrupt, multi-clock mode is restored.

If a SLEEP instruction is executed while the SSBY bit in SBYCR is set to 1, this LSI enters software standby mode. When software standby mode is cleared by an external interrupt, multi-clock mode is restored.

When the  $\overline{\text{RES}}$  pin is driven low, the reset state is entered and multi-clock mode is cleared. The same applies to a reset caused by watchdog timer overflow.

## 19.4 Module Stop Mode

Module stop mode can be set for individual on-chip peripheral modules.

When the corresponding MSTP bit in MSTPCRA, MSTPCRB, or MSTPCRC is set to 1, module operation stops at the end of the bus cycle and a transition is made to module stop mode. The CPU continues operating independently.

When the corresponding MSTP bit is cleared to 0, module stop mode is cleared and the module starts operating at the end of the bus cycle. In module stop mode, the internal states of modules other than the SCI, RCAN-ET and SSU are retained.

After the reset state is cleared, all modules other than the DMAC and on-chip RAM are in module stop mode.

The registers of the module for which module stop mode is selected cannot be read from or written to.

## 19.5 Sleep Mode

### 19.5.1 Transition to Sleep Mode

When the SLEEP instruction is executed when the SSBY bit in SBYCR is 0, the CPU enters sleep mode. In sleep mode, CPU operation stops but the contents of the CPU's internal registers are retained. Other peripheral functions do not stop.

### 19.5.2 Clearing Sleep Mode

Sleep mode is exited by any interrupt, signals on the  $\overline{\text{RES}}$  pin, and a reset caused by a watchdog timer overflow.

1. Clearing by interrupt

When an interrupt occurs, sleep mode is exited and interrupt exception processing starts. Sleep mode is not exited if the interrupt is disabled, or interrupts other than NMI are masked by the CPU.

2. Clearing by  $\overline{\text{RES}}$  pin

Setting the  $\overline{\text{RES}}$  pin level low selects the reset state. After the stipulated reset input duration, driving the  $\overline{\text{RES}}$  pin high makes the CPU start the reset exception processing.

3. Clearing by reset caused by watchdog timer overflow

Sleep mode is exited by an internal reset caused by a watchdog timer overflow.

## 19.6 All-Module-Clock-Stop Mode

When the ACSE bit in MSTPCRA is set to 1 and all modules controlled by MSTPCR are stopped (MSTPCRA, MSTPCRB = H'FFFFFFF, MSTPCRC = H'FF00), executing a SLEEP instruction with the SSBY bit in SBYCR cleared to 0 will cause all modules (except for the watchdog timer), the bus controller, and the I/O ports to stop operating, and to make a transition to all-module-clock-stop mode at the end of the bus cycle.

All-module-clock-stop mode is cleared by an external interrupt (NMI or  $\overline{\text{IRQ0}}$  to  $\overline{\text{IRQ14}}$  pins),  $\overline{\text{RES}}$  pin input, or an internal interrupt (watchdog timer), and the CPU returns to the normal program execution state via the exception handling state. All-module-clock-stop mode is not cleared if interrupts are disabled or interrupts other than NMI are masked on the CPU side.

## 19.7 Software Standby Mode

### 19.7.1 Transition to Software Standby Mode

If a SLEEP instruction is executed when the SSBY bit in SBYCR is set to 1, software standby mode is entered. In this mode, the CPU, on-chip peripheral functions, and oscillator all stop. However, the contents of the CPU's internal registers, on-chip RAM data, and the states of on-chip peripheral functions other than the SCI, RCAN-ET, and SSU, and the states of the I/O ports, are retained. In this mode the oscillator stops, allowing power consumption to be significantly reduced.

If the WDT is used as a watchdog timer, it is impossible to make a transition to software standby mode. The WDT should be stopped before the SLEEP instruction execution.

### 19.7.2 Clearing Software Standby Mode

Software standby mode is cleared by an external interrupt (NMI pin, or pins  $\overline{\text{IRQ0}}$  to  $\overline{\text{IRQ14}}$ \*), or by means of the  $\overline{\text{RES}}$  pin.

#### 1. Clearing by interrupt

When an NMI or IRQ0 to IRQ14\* interrupt request signal is input, clock oscillation starts, and after the elapse of the time set in bits STS4 to STS0 in SBYCR, stable clocks are supplied to the entire LSI, software standby mode is cleared, and interrupt exception handling is started.

When clearing software standby mode with an  $\overline{\text{IRQ0}}$  to  $\overline{\text{IRQ14}}$ \* interrupt, set the corresponding enable bit to 1 and ensure that no interrupt with a higher priority than interrupts  $\overline{\text{IRQ0}}$  to  $\overline{\text{IRQ11}}$ \* is generated. Software standby mode cannot be cleared if the interrupt has been masked on the CPU side or has been designated as a DMAC activation source.

Note: \* By setting the SSIn bit in SSIER to 1,  $\overline{\text{IRQ0}}$  to  $\overline{\text{IRQ14}}$  can be used as a software standby mode clearing source.

#### 2. Clearing by $\overline{\text{RES}}$ pin

When the  $\overline{\text{RES}}$  pin is driven low, clock oscillation is started. At the same time as clock oscillation starts, clocks are supplied to the entire LSI. Note that the  $\overline{\text{RES}}$  pin must be held low until clock oscillation settles. When the  $\overline{\text{RES}}$  pin goes high, the CPU begins reset exception handling.

### 19.7.3 Setting Oscillation Settling Time after Clearing Software Standby Mode

Bits STS4 to STS0 in SBYCR should be set as described below.

1. Using a crystal resonator

Set bits STS4 to STS0 so that the standby time is at least equal to the oscillation settling time.

Table 19.2 shows the standby times for operating frequencies and settings of bits STS4 to STS0.

2. Using an external clock

A PLL circuit settling time is necessary. Refer to table 19.2 to set the standby time.

**Table 19.2 Oscillation Settling Time Settings**

STS4	STS3	STS2	STS1	STS0	Standby Time	P $\phi$ * [MHz]			Unit							
						35	25	20								
0	0	0	0	0	Reserved	—	—	—	$\mu$ s

 : Recommended time setting when using a crystal resonator.

 : Recommended time setting when using an external clock.

Note: \*  $\phi$  is the output from the peripheral module frequency divider.

### 19.7.4 Software Standby Mode Application Example

Figure 19.2 shows an example in which a transition is made to software standby mode at the falling edge on the NMI pin, and software standby mode is cleared at the rising edge on the NMI pin.

In this example, an NMI interrupt is accepted with the NMIEG bit in INTCR cleared to 0 (falling edge specification), then the NMIEG bit is set to 1 (rising edge specification), the SSBY bit is set to 1, and a SLEEP instruction is executed, causing a transition to software standby mode.

Software standby mode is then cleared at the rising edge on the NMI pin.

**Figure 19.2 Software Standby Mode Application Example**

## 19.8 B $\phi$ Clock Output Control

Output of the B $\phi$  clock can be controlled by bits PSTOP1 and POSEL1 in SCKCR, and DDR for the corresponding PA7 pin.

Clearing both bits PSTOP1 and POSEL1 to 0 enables the B $\phi$  clock output on the PA7 pin. When bit PSTOP1 is set to 1, the B $\phi$  clock output stops at the end of the bus cycle, and the B $\phi$  clock output goes high. When DDR for the PA7 pin is cleared to 0, the B $\phi$  clock output is disabled and the pin becomes an input port.

Disabling B $\phi$  output can reduce electromagnetic interference (EMI). Take it into consideration for design of the user system board.

Tables 19.3 shows the states of the B $\phi$  pin in each processing state.

**Table 19.3 B $\phi$  Pin (PA7) State in Each Processing State**

Register Setting Value			Normal Operating State	Sleep Mode	All-Module- Clock-Stop Mode	Software Standby Mode	
DDR	PSTOP1	POSEL1				OPE = 0	OPE = 1
0	X	X	Hi-Z	Hi-Z	Hi-Z	Hi-Z	Hi-Z
1	0	0	B $\phi$ output	B $\phi$ output	B $\phi$ output	High	High
1	0	1	Setting prohibited	Setting prohibited	Setting prohibited	Setting prohibited	Setting prohibited
1	1	X	High	High	High	High	High

## **19.9 Usage Notes**

### **19.9.1 I/O Port Status**

In software standby mode, the I/O port states are retained. Therefore, there is no reduction in current consumption for the output current when a high-level signal is output.

### **19.9.2 Current Consumption during Oscillation Settling Standby Period**

Current consumption increases during the oscillation settling standby period.

### **19.9.3 DMAC Module Stop**

Depending on the operating state of the DMAC, bit MSTPA13 may not be set to 1. Setting of the DMAC module stop mode should be carried out only when the DMAC is not activated.

For details, refer to section 7, DMA Controller (DMAC).

### **19.9.4 On-Chip Peripheral Module Interrupts**

Relevant interrupt operations cannot be performed in module stop mode. Consequently, if module stop mode is entered when an interrupt has been requested, it will not be possible to clear the CPU interrupt source or the DMAC activation source. Interrupts should therefore be disabled before entering module stop mode.

### **19.9.5 Writing to MSTPCRA, MSTPCRB, and MSTPCRC**

MSTPCRA, MSTPCRB, and MSTPCRC should only be written to by the CPU.

## Section 20 List of Registers

The register list gives information on the on-chip I/O register addresses, how the register bits are configured, and the register states in each operating mode. The information is given as shown below.

1. Register addresses (address order)
  - Registers are listed from the lower allocation addresses.
  - Registers are classified according to functional modules.
  - Undefined and reserved addresses cannot be accessed. Do not access these addresses; otherwise, the operation when accessing these bits and subsequent operations cannot be guaranteed.
2. Register bits
  - Bit configurations of the registers are listed in the same order as the register addresses.
  - Reserved bits are indicated by — in the bit name column.
  - Space in the bit name field indicates that the entire register is allocated to either the counter or data.
  - For the registers of 16 or 32 bits, the MSB is listed first.  
Byte configuration description order is subject to big endian.
3. Register states in each operating mode
  - Register states are listed in the same order as the register addresses.
  - For the initialized state of each bit, refer to the register description in the corresponding section.
  - The register states shown here are for the basic operating modes. If there is a specific reset for an on-chip peripheral module, refer to the section on that on-chip peripheral module.

## 20.1 Register Addresses (Address Order)

Register Name	Abbreviation	Number of Bits	Address	Module	Data Width	Access Cycles
Master control register	MCR	16	H'FEA00	RCAN-ET	16	4P $\phi$ /4P $\phi$
General status register	GSR	16	H'FEA02	RCAN-ET	16	4P $\phi$ /4P $\phi$
Bit configuration register 1	BCR1	16	H'FEA04	RCAN-ET	16	4P $\phi$ /4P $\phi$
Bit configuration register 0	BCR0	16	H'FEA06	RCAN-ET	16	4P $\phi$ /4P $\phi$
Interrupt request register	IRR	16	H'FEA08	RCAN-ET	16	4P $\phi$ /4P $\phi$

- Notes: 1. The lower 20 bits are indicated.  
 2. Supported only by the H8SX/1527R.

## 20.2 Register Bits

Register addresses and bit names of the on-chip peripheral modules are described below.

Each line covers eight bits, and 16-bit and 32-bit registers are shown as 2 or 4 lines, respectively.

Register Abbreviation	Bit 31/23/15/7	Bit 30/22/14/6	Bit 29/21/13/5	Bit 28/20/12/4	Bit 27/19/11/3	Bit 26/18/10/2	Bit 25/17/9/1	Bit 24/16/8/0	Module

## Section 21 Electrical Characteristics

### 21.1 Absolute Maximum Ratings

**Table 21.1 Absolute Maximum Ratings**

Item	Symbol	Value	Unit
Power supply voltage	$V_{CC}$	-0.3 to +7.0	V
Input voltage (except ports 4 and 5)	$V_{in}$	-0.3 to $V_{CC} + 0.3$	V
Input voltage (port 4)	$V_{in}$	-0.3 to $AV_{CC1} + 0.3$	V
Input voltage (port 5)	$V_{in}$	-0.3 to $AV_{CC0} + 0.3$	V
Analog power supply voltage	$AV_{CC0}$	-0.3 to +7.0	V
	$AV_{CC1}$	-0.3 to +7.0	V
Analog input voltage (port 4)	$V_{AN}$	-0.3 to $AV_{CC1} + 0.3$	V
Analog input voltage (port 5)	$V_{AN}$	-0.3 to $AV_{CC0} + 0.3$	V
Operating temperature	$T_{opr}$	Wide-range specifications: -40 to +85*	°C
Storage temperature	$T_{stg}$	-55 to +125	°C

Caution: Permanent damage to the LSI may result if absolute maximum ratings are exceeded.

Note: \* The operating temperature when programming/erasing the flash memory ranges from 0°C to +85°C for wide-range specification products.

## 21.2 DC Characteristics

**Table 21.2 DC Characteristics (1)**

Conditions:  $V_{CC} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC0} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC1} = 4.5\text{ V to }5.5\text{ V}$ ,  
 $V_{SS} = AV_{SS} = 0\text{ V}^{*1}$ ,  $T_a = -40^\circ\text{C to }+85^\circ\text{C}$  (wide-range specifications)

	Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Schmitt trigger input voltage	$\overline{\text{IRQ}}$ input pin, TPU input pin, ports 2, 3, J, K	$VT^-$	$V_{CC} \times 0.2$	—	—	V	
		$VT^+$	—	—	$V_{CC} \times 0.7$		
		$VT^+ - VT^-$	$V_{CC} \times 0.05$	—	—		
Input high voltage (except Schmitt trigger input pin)	MD, $\overline{\text{RES}}$ , NMI	$V_{IH}$	$V_{CC} - 0.7$	—	$V_{CC} + 0.3$	V	
	EXTAL		$V_{CC} \times 0.7$	—	$V_{CC} + 0.3$		
	Other input pins		$V_{CC} \times 0.7$	—	$V_{CC} + 0.3$		
	Port 4		$AV_{CC1} \times 0.7$	—	$AV_{CC1} + 0.3$		
	Port 5		$AV_{CC0} \times 0.7$	—	$AV_{CC0} + 0.3$		
Input low voltage (except Schmitt trigger input pin)	$\overline{\text{RES}}$ , MD, NMI	$V_{IL}$	-0.3	—	$V_{CC} \times 0.1$	V	
	EXTAL		-0.3	—	$V_{CC} \times 0.2$		
	Other pins		-0.3	—	$V_{CC} \times 0.2$		
	Port 4		-0.3	—	$AV_{CC1} \times 0.2$		
	Port 5		-0.3	—	$AV_{CC0} \times 0.2$		
Output high voltage	All output pins	$V_{OH}$	$V_{CC} - 0.5$	—	—	V	$I_{OH} = -200\ \mu\text{A}$
			$V_{CC} - 1.0$	—	—		$I_{OH} = -1\ \text{mA}$
Output low voltage	All output pins	$V_{OL}$	—	—	0.4	V	$I_{OL} = 1.6\ \text{mA}$
Input leakage current	$\overline{\text{RES}}$ , NMI, MD	$ I_{in} $	—	—	1.0	$\mu\text{A}$	$V_{in} = 0.5\text{ to }V_{CC} - 0.5\text{ V}$
	Port 4		—	—	1.0		$V_{in} = 0.5\text{ to }AV_{CC1} - 0.5\text{ V}$
	Port 5		—	—	1.0		$V_{in} = 0.5\text{ to }AV_{CC0} - 0.5\text{ V}$

**Table 21.2 DC Characteristics (2)**

Conditions:  $V_{CC} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC0} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC1} = 4.5\text{ V to }5.5\text{ V}$ ,  
 $V_{SS} = AV_{SS} = 0\text{ V}^{*1}$ ,  $T_a = -40^\circ\text{C to }+85^\circ\text{C}$  (wide-range specifications)

	Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Tri-state leakage current (off state)	Ports 1 to 3, 6, A, D, H, J, K	$ I_{TSI} $	—	—	1.0	$\mu\text{A}$	$V_{in} = 0.5\text{ to }V_{CC} - 0.5\text{ V}$
Input pull-up MOS current	Ports D, H, J, K	$-I_p$	50	—	300	$\mu\text{A}$	$V_{in} = 0\text{ V}$
Input capacitance	All input pins	$C_{in}$	—	—	15	pF	$V_{in} = 0\text{ V}$ $f = 1\text{ MHz}$ $T_a = 25^\circ\text{C}$
Current consumption* <sup>2</sup>	Normal operation	$I_{CC}^{*4}$	—	75	87	mA	$f = 48\text{ MHz}$
	Sleep mode		—	58	68		
	Standby mode* <sup>3</sup>		—	50	300		$T_a \leq 50^\circ\text{C}$
				—	—	1	$50^\circ\text{C} < T_a$
	All-module-clock-stop mode* <sup>5</sup>		—	36	45		
Analog power supply current	During A/D conversion	$AI_{CC0}$	—	3.5	5		$AV_{CC0} = 5.0\text{ V}$
	Standby for A/D conversion		—	10	100	$\mu\text{A}$	
	During A/D conversion	$AI_{CC1}$	—	3.5	5	mA	$AV_{CC1} = 5.0\text{ V}$
	Standby for A/D conversion		—	10	100	$\mu\text{A}$	
RAM standby voltage		$V_{RAM}$	3.0	—	—	V	

- Notes: 1. When the A/D converter is not used, the  $AV_{CC0}$ ,  $AV_{CC1}$ , and  $AV_{SS}$  pins should not be open. Connect the  $AV_{CC0}$  and  $AV_{CC1}$  pins to  $V_{CC}$ , and the  $AV_{SS}$  pin to  $V_{SS}$ .
2. Current consumption values are for  $V_{IH} = AV_{CC0}$  (port 5),  $AV_{CC1}$  (port 4),  $V_{CC}$  (others) and  $V_{IL} = 0\text{ V}$  with all output pins unloaded and all input pull-up MOSs in the off state.
3. The values are for  $V_{RAM} \leq V_{CC} < 4.5\text{ V}$ ,  $V_{IH\text{min.}} = V_{CC} - 0.1\text{ V}$ , and  $V_{IL\text{max.}} = 0.1\text{ V}$ .
4.  $I_{CC}$  depends on  $V_{CC}$  and  $f$  as follows:  
 $I_{CC\text{max}} = 12\text{ (mA)} + 0.28\text{ (mA/(MHz} \times \text{V))} \times V_{CC} \times f$  (normal operation)  
 $I_{CC\text{max}} = 12\text{ (mA)} + 0.21\text{ (mA/(MHz} \times \text{V))} \times V_{CC} \times f$  (sleep mode)
5. The values are for reference.

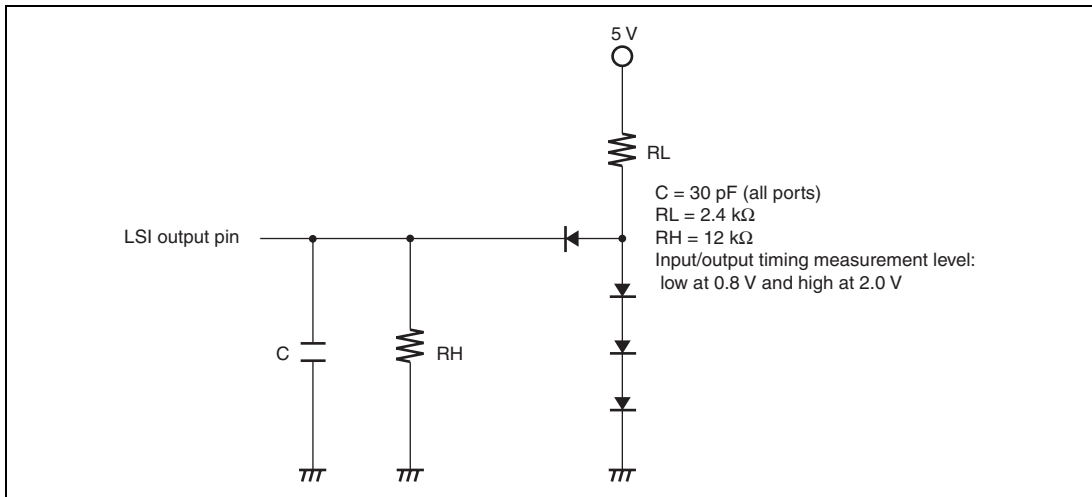

**Table 21.3 Permissible Output Currents**

Conditions:  $V_{CC} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC0} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC1} = 4.5\text{ V to }5.5\text{ V}$ ,  
 $V_{SS} = AV_{SS} = 0\text{ V}^*$ ,  $T_a = -40^\circ\text{C to }+85^\circ\text{C}$  (wide-range specifications)

Item	Symbol	Min.	Typ.	Max.	Unit
Permissible output low current (per pin)	$I_{OL}$	—	—	10	mA
Permissible output low current (total)	$\Sigma I_{OL}$	—	—	100	mA
Permissible output high current (per pin)	$-I_{OH}$	—	—	2.0	mA
Permissible output high current (total)	$\Sigma -I_{OH}$	—	—	30	mA

Caution: To protect the LSI's reliability, do not exceed the output current values in table 21.11.

Note: \* When the A/D converter is not used, the  $AV_{CC0}$ ,  $AV_{CC1}$ , and  $AV_{SS}$  pins should not be open. Connect the  $AV_{CC0}$  and  $AV_{CC1}$  pins to  $V_{CC}$ , and the  $AV_{SS}$  pin to  $V_{SS}$ .

### 21.3.1 Clock Timing

**Table 21.4 Clock Timing**

Conditions:  $V_{CC} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC0} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC1} = 4.5\text{ V to }5.5\text{ V}$ ,  
 $V_{SS} = AV_{SS} = 0\text{ V}$ ,  $I\phi = 8\text{ to }48\text{ MHz}$ ,  $P\phi = 8\text{ to }35\text{ MHz}$ ,  
 $T_a = -40^\circ\text{C to }+85^\circ\text{C}$  (wide-range specifications)

Item	Symbol	Min.	Max.	Unit.	Test Conditions
Clock cycle time	$t_{cyc}$	20.8	125	ns	Figure 21.2
Clock high pulse width	$t_{CH}$	3	—	ns	
Clock low pulse width	$t_{CL}$	3	—	ns	
Clock rising time	$t_{Cr}$	—	5	ns	
Clock falling time	$t_{Cf}$	—	5	ns	
Oscillation settling time after reset (crystal)	$t_{OSC1}$	20	—	ms	Figure 21.4
Oscillation settling time after leaving software standby mode (crystal)	$t_{OSC2}$	10	—	ms	Figure 21.3
External clock output delay settling time	$t_{DEXT}$	2	—	ms	Figure 21.4
External clock input low pulse width	$T_{EXL}$	45	—	ns	Figure 21.5
External clock input high pulse width	$T_{EXH}$	45	—	ns	External clock input frequency = 4 to 9 MHz
External clock rising time	$T_{EXr}$	—	5	ns	
External clock falling time	$T_{EXf}$	—	5	ns	

**Figure 21.2 System Bus Clock Timing**

**Figure 21.3 Oscillation Settling Timing after Software Standby Mode**

**Figure 21.4 Oscillation Settling Timing**

**Figure 21.5 External Input Clock Timing**

### 21.3.2 Control Signal Timing

**Table 21.5 Control Signal Timing**

Conditions:  $V_{CC} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC0} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC1} = 4.5\text{ V to }5.5\text{ V}$ ,  
 $V_{SS} = AV_{SS} = 0\text{ V}$ ,  $I\phi = 8\text{ to }48\text{ MHz}$ ,  
 $T_a = -40^\circ\text{C to }+85^\circ\text{C}$  (wide-range specifications)

Item	Symbol	Min.	Max.	Unit	Test Conditions
$\overline{\text{RES}}$ setup time	$t_{\text{RESS}}$	1000	—	ns	Figure 21.6
$\overline{\text{RES}}$ pulse width	$t_{\text{RESW}}$	50	—	$t_{\text{cyc}}$	
NMI setup time	$t_{\text{NMIS}}$	150	—	ns	Figure 21.7
NMI hold time	$t_{\text{NMIH}}$	10	—	ns	
NMI pulse width (after leaving software standby mode)	$t_{\text{NMIW}}$	200	—	ns	
$\overline{\text{IRQ}}$ setup time	$t_{\text{IRQS}}$	150	—	ns	
$\overline{\text{IRQ}}$ hold time	$t_{\text{IRQH}}$	10	—	ns	
$\overline{\text{IRQ}}$ pulse width (after leaving software standby mode)	$t_{\text{IRQW}}$	200	—	ns

### 21.3.3 Timing of On-Chip Peripheral Modules

**Table 21.6 Timing of On-Chip Peripheral Modules (1)**

Conditions:  $V_{CC} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC0} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC1} = 4.5\text{ V to }5.5\text{ V}$ ,  
 $V_{SS} = AV_{SS} = 0\text{ V}$ ,  $P\phi = 8\text{ to }35\text{ MHz}$ ,  
 $T_a = -40^\circ\text{C to }+85^\circ\text{C}$  (wide-range specifications)

	Item	Symbol	Min.	Max.	Unit	Test Conditions	
I/O ports	Output data delay time	$t_{PWD}$	—	40	ns	Figure 21.8	
	Input data setup time	$t_{PRS}$	25	—	ns		
	Input data hold time	$t_{PRH}$	25	—	ns		
	Realtime input port data hold time	$t_{RTIPH}$	4	—	$t_{cyc}$	Figure 21.9	
TPU	Timer output delay time	$t_{TOCD}$	—	40	ns	Figure 21.10	
	Timer input setup time	$t_{TICS}$	25	—	ns		
	Timer clock input setup time	$t_{TCKS}$	25	—	ns	Figure 21.11	
	Timer clock pulse width	Single-edge setting	$t_{TCKWH}$	1.5	—	$t_{cyc}$	
		Both-edge setting	$t_{TCKWL}$	2.5	—	$t_{cyc}$	

	Item	Symbol	Min.	Max.	Unit	Test Conditions	
PPG	Pulse output delay time	$t_{POD}$	—	40	ns	Figure 21.12	
SCI	Input clock cycle	Asynchronous	$t_{Seyc}$	4	—	$t_{cyc}$	Figure 21.13
		Clocked synchronous		6	—		
	Input clock pulse width	$t_{SCKW}$	0.4	0.6	$t_{Seyc}$		
	Input clock rise time	$t_{SCKr}$	—	20	ns	Figure 21.13	
	Input clock fall time	$t_{SCKf}$	—	20	ns	Measurement voltages: $V_{CC} \times 0.3$ V to $V_{CC} \times 0.7$ V	
	Output clock cycle	Asynchronous	$t_{Seyc}$	30	—		$t_{cyc}$
		Clocked synchronous		4	—		
	Output clock pulse width	$t_{SCKW}$	0.4	0.6	$t_{Seyc}$		
	Output clock rise time	$t_{SCKr}$	—	20	ns	Figure 21.13	
	Output clock fall time	$t_{SCKf}$	—	20	ns	Measurement voltages: $V_{CC} \times 0.3$ V to $V_{CC} \times 0.7$ V	
	Transmit data delay time	$t_{TXD}$	—	40	ns		Figure 21.14
	Receive data setup time (clocked synchronous)	$t_{RXS}$	40	—	ns		
	Receive data hold time (clocked synchronous)	$t_{RXH}$	40	—	ns		
A/D converter	Trigger input setup time	$t_{TRGS}$	30	—	ns	Figure 21.15	

**Table 21.6 Timing of On-Chip Peripheral Modules (2)**

Conditions:  $V_{CC} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC0} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC1} = 4.5\text{ V to }5.5\text{ V}$ ,  
 $V_{SS} = AV_{SS} = 0\text{ V}$ ,  $P\phi = 8\text{ to }24\text{ MHz}$ ,  
 $T_a = -40^\circ\text{C to }+85^\circ\text{C}$  (wide-range specifications)

	Item	Symbol	Min.	Max.	Unit	Test Conditions	
RCAN-ET*	Transmit data delay time	$t_{CTXD}$	—	100	ns	Figure 21.16	
	Receive data setup time	$t_{CRXS}$	100	—	ns		
	Receive data hold time	$t_{CRXH}$	100	—	ns		
SSU	Clock cycle time	Master	$t_{SUcyc}$	4	256	$t_{cyc}$	Figure 21.17
		Slave		4	256		Figure 21.18
	Clock high pulse width	Master	$t_{HI}$	80	—	ns	Figure 21.19
		Slave		80	—		Figure 21.20
	Clock low pulse width	Master	$t_{LO}$	80	—	ns	
		Slave		80	—		
	Clock rising time		$t_{RISE}$	—	20	ns

	$\overline{SCS}$ hold time	Master	$t_{LAG}$	2.5	—	$t_{cyc}$	
		Slave		2.5	—		
	Data output delay time	Master	$t_{OD}$	—	40	ns	
		Slave		—	40		
	Data output hold time	Master	$t_{OH}$	30	—	ns	
		Slave		30	—		
Consecutive transmit delay time	Master	$t_{TD}$	2.5	—	$t_{cyc}$		
	Slave		2.5	—			

Item		Symbol	Min.	Max.	Unit	Test Conditions
SSU	Slave access time	$t_{SA}$	—	1	$t_{cyc}$	Figure 21.19
	Slave out release time	$t_{REL}$	—	1	$t_{cyc}$	Figure 21.20

Note: \* Although the RCAN-ET input signals are asynchronous signals, they are received as the signals in synchronization with every other rising edge of the  $P\phi$  clock (see Figure 21.16). The RCAN-ET output signals are also asynchronous signals, however, change their levels based on every other rising edge of the  $P\phi$  clock.

## 21.4 A/D Conversion Characteristics

**Table 21.7 A/D Conversion Characteristics**

Conditions:  $V_{CC} = 4.5 \text{ V to } 5.5 \text{ V}$ ,  $AV_{CC0} = 4.5 \text{ V to } 5.5 \text{ V}$ ,  $AV_{CC1} = 4.5 \text{ V to } 5.5 \text{ V}$ ,  
 $V_{SS} = AV_{SS} = 0 \text{ V}$ ,  $P\phi = 8 \text{ to } 35 \text{ MHz}$ ,  
 $T_a = -40^\circ\text{C to } +85^\circ\text{C}$  (wide-range specifications)

Item	Min.	Typ.	Max.	Unit
Resolution	10	10	10	Bit
Conversion time	7.4	—	200	$\mu\text{s}$
Analog input capacitance	—	—	20	pF
Permissible signal source impedance	—	—	5	$\text{k}\Omega$
Nonlinearity error	—	—	$\pm 3.5$	LSB
Offset error	—	—	$\pm 3.5$	LSB
Full-scale error	—	—	$\pm 3.5$	LSB
Quantization error	—	$\pm 0.5$	—	LSB
Absolute accuracy	—	—	$\pm 4.0$	LSB

## 21.5 Flash Memory Characteristics

**Table 21.8 Flash Memory Characteristics**

Conditions:  $V_{CC} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC0} = 4.5\text{ V to }5.5\text{ V}$ ,  $AV_{CC1} = 4.5\text{ V to }5.5\text{ V}$ ,  
 $V_{SS} = AV_{SS} = 0\text{ V}$ ,  $I\phi = 8\text{ to }48\text{ MHz}$ ,  $P\phi = 8\text{ to }35\text{ MHz}$ ,  
 $T_a = 0^\circ\text{C to }+85^\circ\text{C}$  (wide-range specifications)

Item	Symbol	Min.	Typ.	Max.	Unit	Test Condition
Programming time* <sup>1</sup> * <sup>2</sup> * <sup>4</sup>	$t_p$	—	3	30	ms/128 bytes	
Erase time* <sup>1</sup> * <sup>2</sup> * <sup>4</sup>	$t_E$	—	80	800	ms/4-kbyte block	
			500	5000	ms/32-kbyte block	
			1000	10000	ms/64-kbyte block	
Programming time (total) * <sup>1</sup> * <sup>2</sup> * <sup>4</sup>	$\Sigma t_p$	—	5	15	s/256 kbytes	$T_a = 25^\circ\text{C}$ , memory filled with 0.
Erase time (total) * <sup>1</sup> * <sup>2</sup> * <sup>4</sup>	$\Sigma t_E$	—	5	15	s/256 kbytes	$T_a = 25^\circ\text{C}$
Programming/erase time (total) * <sup>1</sup> * <sup>2</sup> * <sup>4</sup>	$\Sigma t_{PE}$	—	10	30	s/256 kbytes	$T_a = 25^\circ\text{C}$
Number of programming	$N_{WEC}$	100* <sup>3</sup>	—	—	Times	
Data retention time* <sup>4</sup>	$t_{DRP}$	10	—	—	Year	

- Notes: 1. Programming time and erase time depend on data in the flash memory.  
2. Programming time and erase time do not include time for data transfer.  
3. All the characteristics after programming are guaranteed within this value (guaranteed value is from 1 to Min. value).  
4. Characteristics when programming is performed within the Min. value

# Appendix

## A. Port States in Each Pin State

**Table A.1 Port States in Each Pin State**

<b>Port Name</b>	<b>MCU Operating Mode</b>	<b>Reset</b>	<b>Software Standby Mode</b>
Port 1	All	Hi-Z	Keep
Port 2	All	Hi-Z	Keep
Port 3	All	Hi-Z	Keep
Port 4	All	Hi-Z	Hi-Z
Port 5	All	Hi-Z	Hi-Z
Port 6	All	Hi-Z	Keep
Port A	All	Hi-Z	Keep
Port D	All	Hi-Z	Keep
Port H	All	Hi-Z	Keep
Port J	All	Hi-Z	Keep
Port K	All	Hi-Z	Keep

**B. Product Lineup**

<b>Product Classification</b>	<b>Product Model</b>	<b>Marking</b>	<b>Package</b>	<b>Package Code</b>
H8SX/1527R	R5F61527R	R5F61527R	QFP-100	PRQP0100KB-A
H8SX/1525R	R5F61525R	R5F61525R		(FP-100M)

### C. Package Dimensions

For the package dimensions, data in the Renesas IC Package General Catalog has priority.

Figure C.1 Package Dimensions (FP-100M)

# Index

## Numerics

0-output/1-output .....	302
16-bit timer pulse unit (TPU) .....	251

## A

A/D conversion accuracy .....	573
A/D converter .....	559
Absolute accuracy .....	573
Absolute maximum ratings .....	757
AC characteristics .....	760
Address error .....	77
Address error exception handling .....	78
Address map .....	70
Address modes .....	158
All-module-clock-stop mode .....	688, 696
Asynchronous mode .....	406
AT-cut parallel-resonance type .....	681
Available output signal and settings in each port .....	239

## B

B $\phi$ clock output control .....	701
Bit rate .....	399
Block diagram .....	2
Block structure .....	587
Block transfer mode .....	164
Boot mode .....	584, 613
Burst mode .....	169
Bus access modes .....	168
Bus arbitration .....	131
Bus configuration .....	127
Bus controller (BSC) .....	125
Bus-released state .....	63

## C

CAN interface .....	453
Can sleep mode .....	500
Clock .....	409
Clock pulse generator .....	677
Clock synchronous communication mode .....	550
Clocked synchronous mode .....	423
Communications protocol .....	646
Controller area network (RCAN-ET) .....	449
CPU priority control function over DMAC .....	118
Crystal resonator .....	681
Cycle stealing mode .....	168

## D

Data direction register .....	212
Data register .....	212
DC characteristics .....	758
Direct convention .....	431
DMA controller (DMAC) .....	133
Double-buffered structure .....	406
Download pass/fail result parameter .....	601
Dual address mode .....	158

## E

Electrical characteristics .....	757
Error protection .....	638
Error signal .....	431
Exception handling .....	71
Exception handling by illegal instruction .....	82
Exception handling vector table .....	72
Exception-handling state .....	63
Extended repeat area .....	156

Extended repeat area function .....	170
External bus clock (B $\phi$ ) .....	677
External clock .....	682
External interrupts .....	101
External trigger input .....	572

## F

Flash erase block select parameter .....	610
Flash memory .....	581
Flash multipurpose address area parameter .....	608
Flash multipurpose data destination parameter .....	609
Flash pass and fail parameter .....	602
Flash program/erase frequency parameter .....	607
Free-running count operation .....	300
Frequency divider .....	682
Full-scale error .....	573

## G

General illegal instruction .....	82
General registers .....	29

## H

Halt mode .....	499
Hardware protection .....	637

## I

I/O ports .....	205
ID code .....	417
ID Reorder .....	464
Illegal instruction .....	82
Input buffer control register .....	213
Input capture function .....	303

Internal bus .....	129
Internal interrupts .....	102
Internal peripheral bus .....	127
Internal system bus 1 .....	127
Interrupt .....	79
Interrupt control mode 0 .....	110
Interrupt control mode 2 .....	112
Interrupt controller .....	85
Interrupt exception handling .....	80
Interrupt exception handling sequence ...	114
Interrupt exception handling vector table .....	103
Interrupt response times .....	115
Interrupt sources .....	101
Interrupt sources and vector address offsets .....	103
Interval timer mode .....	373
Inverse convention .....	432
IRQn interrupts .....	101

## L

Local acceptance filter mask (LAFM) ....	461
--	-----

## M

Mailbox .....	452
Mailbox control .....	453
Mailbox structure .....	456
Mark state .....	406, 443
MCU operating modes .....	65
Memory MAT configuration .....	586
Message control field .....	457
Message data fields .....	462
Message receive sequence .....	506
Message transmission sequence .....	504
Micro processor interface (MPI) .....	452
Mode 1 .....	69
Mode 2 .....	69
Mode 3 .....	69

Mode pin.....	65	Port function controller .....	243
Module stop mode .....	695	Port H realtime input data register .....	215
Multi-clock function .....	128, 695	Port register .....	213
Multiprocessor bit.....	417	Port states in each pin state .....	775
Multiprocessor communication function.....	417	Power-down modes.....	687
<b>N</b>		Processing states .....	63
NMI interrupts .....	101	Product lineup .....	776
Nonlinearity error .....	573	Program execution state .....	63
Non-overlapping operation.....	359	Program stop state.....	63
Normal transfer mode .....	162	Programmable pulse generator (PPG).....	345
<b>O</b>		Programmer mode.....	584, 644
Offset addition .....	172	Programming/erasing interface .....	588
Offset error .....	573	Programming/erasing interface parameters .....	599
On-board programming .....	613	Programming/erasing interface register ..	592
On-board programming mode .....	613	Protection .....	637
On-chip baud rate generator .....	409	Pull-up MOS control register .....	214
Open-drain control register.....	215	<b>Q</b>	
Oscillator .....	681	Quantization error .....	573
Output buffer control .....	216	<b>R</b>	
Output trigger .....	358	RAM .....	579
Overflow .....	372	RCAN-ET bit rate calculation.....	474
<b>P</b>		RCAN-ET interrupt sources.....	510
Package.....	1	RCAN-ET memory map .....	454
Package dimensions.....	777	RCAN-ET reset sequence .....	498
Parity bit .....	406	Reconfiguration of Mailbox.....	508
Periodic count operation .....	300	Register addresses.....	704
Peripheral module clock (Pφ) .....	128, 677	Register bits .....	723
Phase counting mode .....	318	Register configuration in each port.....	210
Pin assignments .....	4	Register states in each operating mode .....	743
Pin configuration in each operating mode .....	6	Registers	
Pin functions .....	10	ABACK0 .....	491, 704, 723, 743
PLL circuit.....	682	ADCR .....	567, 720, 740, 754
		ADCSR .....	565, 720, 740, 754
		ADDR .....	564, 720, 740, 753

## RENESAS SALES OFFICES

<http://www.renesas.com>

Refer to "<http://www.renesas.com/en/network>" for the latest and detailed information.

### **Renesas Technology America, Inc.**

450 Holger Way, San Jose, CA 95134-1368, U.S.A  
Tel: <1> (408) 382-7500, Fax: <1> (408) 382-7501

### **Renesas Technology Europe Limited**

Dukes Meadow, Millboard Road, Bourne End, Buckinghamshire, SL8 5FH, U.K.  
Tel: <44> (1628) 585-100, Fax: <44> (1628) 585-900

### **Renesas Technology (Shanghai) Co., Ltd.**

Unit 204, 205, AZIA Center, No.1233 Lujiazui Ring Rd, Pudong District, Shanghai, China 200120  
Tel: <86> (21) 5877-1818, Fax: <86> (21) 6887-7898

### **Renesas Technology Hong Kong Ltd.**

7th Floor, North Tower, World Finance Centre, Harbour City, 1 Canton Road, Tsimshatsui, Kowloon, Hong Kong  
Tel: <852> 2265-6688, Fax: <852> 2730-6071

### **Renesas Technology Taiwan Co., Ltd.**

10th Floor, No.99, Fushing North Road, Taipei, Taiwan  
Tel: <886> (2) 2715-2888, Fax: <886> (2) 2713-2999

### **Renesas Technology Singapore Pte. Ltd.**

1 Harbour Front Avenue, #06-10, Keppel Bay Tower, Singapore 098632  
Tel: <65> 6213-0200, Fax: <65> 6278-8001

### **Renesas Technology Korea Co., Ltd.**

Kukje Center Bldg. 18th Fl., 191, 2-ka, Hangang-ro, Yongsan-ku, Seoul 140-702, Korea  
Tel: <82> (2) 796-3115, Fax: <82> (2) 796-2145

### **Renesas Technology Malaysia Sdn. Bhd**

Unit 906, Block B, Menara Amcorp, Amcorp Trade Centre, No.18, Jalan Persiaran Barat, 46050 Petaling Jaya, Selangor Darul Ehsan, Malaysia  
Tel: <603> 7955-9390, Fax: <603> 7955-9510
