## 12-Bit, $3 \mu \mathrm{~s}, 250 \mathrm{kHz}$ Sampling A/D Converter

## DESCRIPTIOn

The LTC1272 is a $3 \mu \mathrm{~s}, 12$-bit, successive approximation sampling A/D converter. It has the same pinout as the industry standard AD7572 and offers faster conversion time, on-chip sample-and-hold, and single supply operation. It uses LTBiCMOS ${ }^{\text {TM }}$ switched-capacitor technology to combine a high speed 12-bit ADC with a fast, accurate sample-and-hold and a precision reference.
The LTC1272 operates with a single 5V supply but can also accept the 5V/-15V supplies required by the AD7572 (Pin 23 , the negative supply pin of the AD7572, is not connected on the LTC1272). The LTC1272 has the same 0 V to 5 V input range as the AD7572 but, to achieve single supply operation, it provides a 2.42 V reference output instead of the -5.25 V of the AD7572. It plugs in for the AD7572 if the reference capacitor polarity is reversed and a $1 \mu \mathrm{~s}$ sample-and-hold acquisition time is allowed between conversions.
The output data can be read as a 12-bit word or as two 8-bit bytes. This allows easy interface to both 8-bit and higher processors. The LTC1272 can be used with a crystal or an external clock and comes in speed grades of 3 ms and 8 ms .

## TYPICAL APPLICATION

1024 Point FFT, $\mathrm{f}_{\mathrm{S}}=250 \mathrm{kHz}, \mathrm{f}_{\mathrm{IN}}=10 \mathrm{kHz}$

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: All voltage values are with respect to ground with DGND and AGND wired together, unless otherwise noted.
Note 3: When the analog input voltage is taken below ground it will be clamped by an internal diode. This product can handle, with no external diode, input currents of greater than 60 mA below ground without latch-up.
Note 4: $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}$, $\mathrm{f}_{\mathrm{CLK}}=4 \mathrm{MHz}$ for LTC1272-3, and 1.6 MHz for LTC1272-8, $\mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=5$ ns unless otherwise specified. For best analog performance, the LTC1272 clock should be synchronized to the RD and $\overline{\mathrm{CS}}$ control inputs with at least 40ns separating convert start from the nearest clock edge.

Note 5: Linearity error is specified between the actual end points of the A/D transfer curve.
Note 6: The LTC1272 has the same OV to 5V input range as the AD7572 but, to achieve single supply operation, it provides a 2.42 V reference output instead of the -5.25 V of the $\mathrm{AD7572}$. This requires that the polarity of the reference bypass capacitor be reversed when plugging an LTC1272 into an AD7572 socket.
Note 7: Guaranteed by design, not subject to test.
Note 8: $V_{D D}=5 \mathrm{~V}$. Timing specifications are sample tested at $25^{\circ} \mathrm{C}$ to ensure compliance. All input control signals are specified with $\mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=5 \mathrm{~ns}$ ( $10 \%$ to $90 \%$ of 5 V ) and timed from a voltage level of 1.6 V . See Figures 13 through 17.

## PIn functions

$A_{\text {IN }}$ (Pin 1): Analog Input, OV to 5 V Unipolar Input.
$V_{\text {REF }}$ (Pin 2): 2.42 V Reference Output. When plugging into an AD7572 socket, reverse the reference bypass capacitor polarity and short the $10 \Omega$ series resistor.
AGND (Pin 3): Analog Ground.
D11 to D4 (Pins 4-11): Three-State Data Outputs.
DGND (Pin 12): Digital Ground.
D3/11 to D0/8 (Pins 13-16): Three-State Data Outputs.
CLK IN (Pin 17): Clock Input. An external TTL/CMOS compatible clock may be applied to this pin or a crystal can be connected between CLK IN and CLK OUT.

CLK OUT (Pin 18): Clock Output. An inverted CLK IN signal appears at this pin.

HBEN (Pin 19): High Byte Enable Input. This pin is used to multiplex the internal 12-bit conversion result into the lower bit outputs (D7 to D0/8). See table below. HBEN also disables conversion starts when HIGH.
$\overline{\mathrm{RD}}$ (Pin 20): Read Input. This active low signal starts a conversion when $\overline{\mathrm{CS}}$ and HBEN are low. $\overline{\mathrm{RD}}$ also enables the output drivers when $\overline{\mathrm{CS}}$ is low.

CS (Pin 21): The Chip Select Input must be low for the ADC to recognize $\overline{\mathrm{RD}}$ and HBEN inputs.
$\overline{\text { BUSY }}$ (Pin 22): The BUSY Output is low when a conversion is in progress.

NC (Pin 23): Not Connected Internally. The LTC1272 does not require negative supply. This pin can accommodate the -15 V required by the AD7572 without problems.
$V_{D D}$ (Pin 24): Positive Supply, 5V.

## APPLICATIONS INFORMATION

## Conversion Details

Conversion start is controlled by the $\overline{\mathrm{CS}}, \overline{\mathrm{RD}}$ and HBEN inputs. At the start of conversion the successive approximation register (SAR) is reset and the three-state data outputs are enabled. Once a conversion cycle has begun it cannot be restarted.

During conversion, the internal 12-bit capacitive DAC output is sequenced by the SAR from the most significant bit (MSB) to the least significant bit (LSB). Referring to Figure 1, the $\mathrm{A}_{\text {IN }}$ input connects to the sample-and-hold capacitor through a $300 \Omega / 2.7 \mathrm{k} \Omega$ divider. The voltage divider allows the LTC1272 to convert 0 V to 5 V input signals while operating from a 4.5 V supply. The conversion has two phases: the sample phase and the convert phase. During the sample phase, the comparator offset is nulled by the feedback switch and the analog input is stored as a charge on the sample-and-hold capacitor, CsAmpLe. This phase lasts from the end of the previous conversion until the next conversion is started. A minimum delay between conversions ( $\mathrm{t}_{10}$ ) of $1 \mu \mathrm{~s}$ allows enough time for the analog input to be acquired. During the convert phase, the comparator feedback switch opens, putting the comparator into the compare mode. The sample-and-hold capacitor is switched to ground injecting the analog input charge onto the comparator summing junction. This input charge is successively compared to binary weighted charges supplied by the capacitive DAC. Bit decisions are made by the comparator (zero crossing detector) which checks the addition of each successive weighted bit from the DAC output. The MSB decision is made 50ns (typically) after the second falling edge of CLK IN following a conversion start. Similarly, the succeeding bit decisions are made approximately $50 n s$ after a CLK IN edge until the conversion is finished. At the end of a conversion, the DAC output balances the $A_{\text {IN }}$ output charge. The SAR contents (12-bit data word) which represent the $A_{\text {IN }}$ input signal are loaded into a 12-bit latch.

## Sample-and-Hold and Dynamic Performance

Traditionally A/D converters have been characterized by such specs as offset and full-scale errors, integral

Figure 1. $A_{I N}$ Input
nonlinearity and differential nonlinearity. These specs are useful for characterizing an ADC's DC or low frequency signal performance.

These specs alone are not adequate to fully specify the LTC1272 because of its high speed sampling ability. FFT (Fast Fourrier Transform) test techniques are used to characterize the LTC1272's frequency response, distortion and noise at the rated throughput.

By applying a low distortion sine wave and analyzing the digital output using a FFT algorithm, the LTC1272's spectral content can be examined for frequencies outside the fundamental. Figure 2 shows a typical LTC1272 FFT plot.

Figure 2. LTC1272 Non-Averaged, 1024 Point FFT Plot. $\mathrm{f}_{\mathrm{S}}=250 \mathrm{kHz}, \mathrm{f}_{\mathrm{IN}}=10 \mathrm{kHz}$

## APPLICATIONS INFORMATION

Signal-to-Noise Ratio

The Signal-to-Noise Ratio (SNR) is the ratio between the RMS amplitude of the fundamental input frequency to the RMS amplitude of all other frequency components at the A/D output. This includes distortion as well as noise products and for this reason it is sometimes referred to as Signal-to-Noise + Distortion [S/(N + D)]. The output is band limited to frequencies from DC to one half the sampling frequency. Figure 2 shows spectral content from DC to 125 kHz which is $1 / 2$ the 250 kHz sampling rate.

## Effective Number of Bits

The effective number of bits (ENOBs) is a measurement of the resolution of an $A / D$ and is directly related to the $S /(N+D)$ by the equation:

$$
N=[S /(N+D)-1.76] / 6.02,
$$

where N is the effective number of bits of resolution and $\mathrm{S} /(\mathrm{N}+\mathrm{D})$ is expressed in dB . At the maximum sampling rate of 250 kHz the LTC1272 maintains 11.5 ENOBs or better to 20 kHz . Above 20kHz the ENOBs gradually decline, as shown in Figure 3, due to increasing second harmonic distortion. The noise floor remains approximately 90 dB . The dynamic differential nonlinearity remains good out to 120 kHz as shown in Figure 4.

Figure 3. LTC1272 Effective Number of Bits (ENOBs) vs Input Frequency. $\mathrm{f}_{\mathrm{S}}=250 \mathrm{kHz}$

Figure 4. LTC1272 Dynamic DNL. fcLK $=4 \mathrm{MHz}$, $\mathrm{f}_{\mathrm{S}}=250 \mathrm{kHz}, \mathrm{f}_{\mathrm{IN}}=122.25342 \mathrm{kHz}, \mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}$

## Total Harmonic Distortion

Total Harmonic Distortion (THD) is the ratio of the RMS sum of all harmonics of the input signal to the fundamental itself. The harmonics are limited to the frequency band between DC and one half the sampling frequency. THD is expressed as: $20 \mathrm{LOG}\left[\sqrt{\left.V_{2}{ }^{2}+V_{3}{ }^{2}+\ldots+V_{N}{ }^{2} / V_{1}\right] \text { where }}\right.$ $\mathrm{V}_{1}$ is the RMS amplitude of the fundamental frequency and $\mathrm{V}_{2}$ through $\mathrm{V}_{\mathrm{N}}$ are the amplitudes of the second through Nth harmonics.

## Clock and Control Synchronization

For best analog performance, the LTC1272 clock should be synchronized to the $\overline{C S}$ and $\overline{\mathrm{RD}}$ control inputs as shown in Figure 5 , with at least 40 ns separating convert start from the nearest CLK IN edge. This ensures that transitions at CLK IN and CLK OUT do not couple to the analog input and get sampled by the sample-and-hold. The magnitude of this feedthrough is only a few millivolts, but if CLK and convert start ( $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ ) are asynchronous, frequency components caused by mixing the clock and convert signals may increase the apparent input noise.
When the clock and convert signals are synchronized, small endpoint errors (offset and full-scale) are the most that can be generated by clock feedthrough. Even these errors (which can be trimmed out) can be eliminated by ensuring that the start of a conversion ( $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ 's falling edge) does not occur within 40ns of a clock edge, as in

## APPLICATIONS INFORMATION

UNCERTAIN CONVERSION TIME FOR $30 \mathrm{~ns}<\mathrm{t}_{14}<180 \mathrm{~ns}$
*THE LTC1272 IS ALSO COMPATIBLE WITH THE AD7572 SYNCHRONIZATION MODES. LTC1272•TA06
Figure 5. $\overline{\mathrm{RD}}$ and CLK IN for Synchronous Operation

Figure 5. Nevertheless, even without observing this guideline, the LTC1272 is still compatible with AD7572 synchronization modes, with no increase in linearity error. This means that either the falling or rising edge of CLK IN may be near $\overline{\mathrm{RD}}$ 's falling edge.

## Driving the Analog Input

The analog input of the LTC1272 is much easier to drive than that of the AD7572. The input current is not modulated by the DAC as in the AD7572. It has only one small current spike from charging the sample-and-hold capacitor at the end of the conversion. During the conversion the analog input draws only DC current. The only requirement is that the amplifier driving the analog input must settle after the small current spike before the next conversion is started. Any op amp that settles in $1 \mu$ s to small current transients will allow maximum speed operation. If slower op amps are used, more settling time can be provided by increasing the time between conversions. Suitable devices capable of driving the LTC1272 A $_{\text {IN }}$ input include the LT1006 and LT1007 op amps.

## Internal Clock Oscillator

Figure 6 shows the LTC1272 internal clock circuit. A crystal or ceramic resonator may be connected between CLK IN (Pin 17) and CLK OUT (Pin 18) to provide a clock oscillator for ADC timing. Alternatively the crystal/resonator may be omitted and an external clock source may be

NOTES:
LTC1272-3 - 4MHz CRYSTAL/CERAMIC RESONATOR
LTC1272-8 - 1.6MHz CRYSTAL/CERAMIC RESONATOR
LTC1272. TA09

Figure 6. LTC1272 Internal Clock Circuit
connected to CLK IN. For an external clock the duty cycle is not critical. An inverted CLK IN signal will appear at the CLK OUT pin as shown in the operating waveforms of Figure 7. Capacitance on the CLK OUT pin should be minimized for best analog performance.

## Internal Reference

The LTC1272 has an on-chip, temperature compensated, curvature corrected, bandgap reference, which is factory trimmed to $2.42 \mathrm{~V} \pm 1 \%$. It is internally connected to the DAC and is also available at pin 2 to provide up to 1 mA current to an external load.

For minimum code transition noise the reference output should be decoupled with a capacitor to filter wideband noise from the reference ( $10 \mu \mathrm{~F}$ tantalum in parallel with a $0.1 \mu \mathrm{~F}$ ceramic). A simplified schematic of the reference with its recommended decoupling is shown in Figure 8.

## APPLICATIONS INFORMATION

Figure 7. Operating Waveforms Using an External Clock Source for CLK IN

Figure 8. LTC1272 Internal 2.42V Reference

## Unipolar Operation

Figure 9 shows the ideal input/output characteristic for the 0 V to 5 V input range of the LTC1272. The code transitions occur midway between successive integer LSB values
 output code is natural binary with $1 \mathrm{LSB}=\mathrm{FS} / 4096=$ $(5 / 4096) \mathrm{V}=1.22 \mathrm{mV}$.

## Unipolar Offset and Full-Scale Error Adjustment

In applications where absolute accuracy is important, then offset and full-scale error can be adjusted to zero. Offset

Figure 9. LTC1272 Ideal Input/Output Transfer Characteristic
error must be adjusted before full-scale error. Figure 10 shows the extra components required for full-scale error adjustment. Zero offset is achieved by adjusting the offset of the op amp driving $A_{I N}$ (i.e., A1 in Figure 10). For zero offset error apply 0.61 mV (i.e., $1 / 2$ LBS) at $\mathrm{V}_{\text {IN }}$ and adjust the op amp offset voltage until the ADC output code flickers between 000000000000 and 000000000001 .

For zero full-scale error apply an analog input of 4.99817 V (i.e., FS - 3/2LSBs or last code transition) at $\mathrm{V}_{\text {IN }}$ and adjust R1 until the ADC output code flickers between 11111111 1110 and 111111111111.

## APPLICATIONS INFORMATION

Figure 10. Unipolar OV to 5V Operation with Gain Error Adjust

## Application Hints

Wire wrap boards are not recommended for high resolution or high speed A/D converters. To obtain the best performance from the LTC1272 a printed circuit board is required. Layout for the printed circuit board should ensure that digital and analog signal lines are separated as much as possible. In particular, care should be taken not to run any digital track alongside an analog signal track or underneath the LTC1272. The analog input should be screened by AGND.

A single point analog ground separate from the logic system ground should be established with an analog ground plane at pin 3 (AGND) or as close as possible to the LTC1272, as shown in Figure 11. Pin 12 (LTC1272 DGND) and all other analog grounds should be connected to this single analog ground point. No other digital grounds should be connected to this analog ground point. Low impedance analog and digital power supply common returns are essential to low noise operation of the ADC and
the foil width for these tracks should be as wide as possible.

Noise: Input signal leads to $A_{I N}$ and signal return leads from AGND (pin 3) should be kept as short as possible to minimize input noise coupling. In applications where this is not possible, a shielded cable between source and ADC is recommended. Also, since any potential difference in grounds between the signal source and ADC appears as an error voltage in series with the input signal, attention should be paid to reducing the ground circuit impedances as much as possible.

In applications where the LTC1272 data outputs and control signals are connected to a continuously active microprocessor bus, it is possible to get LSB errors in conversion results. These errors are due to feedthrough from the microprocessor to the successive approximation comparator. The problem can be eliminated by forcing the microprocessor into a Wait state during conversion (see Slow Memory Mode interfacing), or by using three-state buffers to isolate the LTC1272 data bus.

## Timing and Control

Conversion start and data read operations are controlled by three LTC1272 digital inputs; HBEN, CS and RD. Figure 12 shows the logic structure associated with these inputs. The three signals are internally gated so that a logic " 0 " is required on all three inputs to initiate a conversion. Once initiated it cannot be restarted until conversion is complete. Converter status is indicated by the BUSY output, and this is low while conversion is in progress.

Figure 11. Power Supply Grounding Practice

## APPLICATIONS INFORMATION

There are two modes of operation as outlined by the timing diagrams of Figures 13 to 17. Slow Memory Mode is designed for microprocessors which can be driven into a Wait state, a Read operation brings $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ low which initiates a conversion and data is read when conversion is complete.

The second is the ROM Mode which does not require microprocessor Wait states. A Read operation brings $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ low which initiates a conversion and reads the previous conversion result.

## Data Format

The output data format can be either a complete parallel load for 16-bit microprocessors or a two byte load for 8-bit microprocessors. Data is always right justified (i.e., LSB is the most right-hand bit in a 16-bit word). For a two byte read, only data outputs D7. . . D0/8 are used. Byte selection is governed by the HBEN input which controls an internal digital multiplexer. This multiplexes the 12 bits of conversion data onto the lower D7. . .D0/8 outputs (4MSBs or 8LSBs) where it can be read in two read cycles. The 4MSBs always appear on D11 . . . D8 whenever the three-state output drives are turned on.

## Slow Memory Mode, Parallel Read (HBEN = Low)

Figure 14 and Table 2 show the timing diagram and data bus status for Slow Memory Mode, Parallel Read. CS and $\overline{\mathrm{RD}}$ going low triggers a conversion and the LTC1272 acknowledges by taking BUSY Iow. Data from the previous conversion appears on the three-state data outputs. BUSY returns high at the end of conversion when the output latches have been updated and the conversion result is placed on data outputs D11 . . . D0/8.

## Slow Memory Mode, Two Byte Read

For a two byte read, only 8 data outputs D7 . . D0/8 are used. Conversion start procedure and data output status for the first read operation is identical to Slow Memory Mode, Parallel Read. See Figure 15 timing diagram and Table 3 data bus status. At the end of conversion the low data byte (DB7 . . . DBO) is read from the ADC. A second Read operation with HBEN high, places the high byte on data outputs $\mathrm{D} 3 / 11 \ldots \mathrm{D} 0 / 8$ and disables conversion start. Note the 4MSBs appear on data outputs D11 . . D8 during the two Read operations above.

## ROM Mode, Parallel Read (HBEN = Low)

The ROM Mode avoids placing a microprocessor into a Wait state. A conversion is started with a Read operation and the 12 bits of data from the previous conversion is available on data outputs D11 . . D0/8 (see Figure 16 and Table 4). This data may be disregarded if not required. A second Read operation reads the new data (DB11 . . DBO) and starts another conversion. A delay at least as long as the LTC1272 conversion time plus the $1 \mu$ s minimum delay between conversions must be allowed between Read operations.

## ROM Mode, Two Byte READ

As previously mentioned for a two byte read, only data outputs D7 . . . D0/8 are used. Conversion is started in the normal way with a Read operation and the data output status is the same as the ROM Mode, Parallel Read. See Figure 17 timing diagram and Table 5 data bus status. Two more Read operations are required to access the new conversion result. A delay equal to the LTC1272 conversion time must be allowed between conversion start and the second data Read operation. The second Read operation, with HBEN high, disables conversion start and places the high byte (4 MSBs) on data outputs D3/11 . . D018. A third read operation accesses the low data byte (DB7 . . . DBO) and starts another conversion. The 4 MSB's appear on data outputs D11 . . . D8 during all three read operations above.

## Microprocessor Interfacing

The LTC1272 is designed to interface with microprocessors as a memory mapped device. The $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ control inputs are common to all peripheral memory interfacing. The HBEN input serves as a data byte select for 8-bit processors and is normally connected to the microprocessor address bus.

## MC68000 Microprocessor

Figure 18 shows a typical interface for the MC68000. The LTC1272 is operating in the Slow Memory Mode. Assuming the LTC1272 is located at address C000, then the following single 16-bit Move instruction both starts a conversion and reads the conversion result:

Move.W \$COOO,DO

## APPLICATIONS INFORMATION

Figure 18. LTC1272 MC68000 Interface
At the beginning of the instruction cycle when the ADC address is selected, $\overline{\text { BUSY }}$ and $\overline{\mathrm{CS}}$ assert $\overline{\text { DTACK, }}$, so that the MC68000 is forced into a Wait state. At the end of conversion $\overline{\mathrm{BUSY}}$ returns high and the conversion result is placed in the DO register of the microprocessor.

## 8085A, Z80 Microprocessor

Figure 19 shows a LTC1272 interface for the Z80 and 8085A. The LTC1272 is operating in the Slow Memory Mode and a two byte read is required. Not shown in the figure is the 8-bit latch required to demultiplex the 8085A common address/data bus. AO is used to assert HBEN, so that an even address (HBEN = LOW) to the LTC1272 will start a conversion and read the low data byte. An odd address (HBEN $=$ HIGH) will read the high data byte. This

Figure 19. LTC1272 8085A/Z80 Interface

is accomplished with the single 16-bit Load instruction below.

$$
\begin{array}{ll}
\text { For the 8085A } & \text { LHLD (B000) } \\
\text { For the Z80 } & \text { LDHL, (B000) }
\end{array}
$$

This is a two byte read instruction which loads the ADC data (address BOOO) into the HL register pair. During the first read operation, $\bar{B} U S Y$ forces the microprocessor to Wait for the LTC1272 conversion. No Wait states are inserted during the second read operation when the microprocessor is reading the high data byte.

## TMS32010 Microcomputer

Figure 20 shows an LTC1272 TMS32010 interface. The LTC1272 is operating in the ROM Mode. The interface is designed for a maximum TMS32010 clock frequency of 18MHz but will typically work over the full TMS32010 clock frequency range.

The LTC1272 is mapped at a port address. The following I/O instruction starts a conversion and reads the previous conversion result into data memory.

IN A,PA
(PA = PORT ADDRESS)
When conversion is complete, a second I/O instruction reads the up-to-date data into memory and starts another conversion. A delay at least as long as the ADC conversion time must be allowed between I/O instructions.

Figure 20. LTC1272 TMS32010 Interface

## APPLICATIONS INFORMATION

## Compatibility with the AD7572

Figure 21 shows the simple, single 5 V configuration recommended for new designs with the LTC1272. If an AD7572 replacement or upgrade is desired, the LTC1272 can be plugged into an AD7572 socket with minor modifications. It can be used as a replacement or to upgrade with sample-and-hold, single supply operation and reduced power consumption.

The LTC1272, while consuming less power overall than the AD7572, draws more current from the 5V supply (it draws no power from the -15 V supply). Also, a $1 \mu \mathrm{~s}$
minimum time between conversions must be provided to allow the sample-and-hold to reacquire the analog input. Figure 22 shows that if the clock is synchronous with $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$, it is only necessary to short out the $10 \Omega$ series resistor and reverse the polarity of the $10 \mu \mathrm{~F}$ bypass capacitor on the $\mathrm{V}_{\text {REF }}$ pin. The -15 V supply is not required and can be removed, or, because there is no internal connection to pin 23, it can remain unmodified. The clock can be considered synchronous with $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ in cases where the LTC1272 CLK IN signal is derived from the same clock as the microprocessor reading the LTC1272.

Figure 21. Single 5V Supply, 3us, 12-Bit Sampling ADC

## APPLICATIONS INFORMATION

Figure 22. Plugging the LTC1272 into an AD7572 Socket Case 1: Clock Synchronous with CS and $\overline{\mathrm{RD}}$

If the clock signal for the AD7572 is derived from a separate crystal or other signal which is not synchronous with the microprocessor clock, then the signals need to be synchronized for the LTC1272 to achieve best analog performance (see Clock and Control Synchronization). The best way to synchronize these signals is to drive the CLK IN pin of the LTC1272 with a derivative of the processor clock, as mentioned above and shown in Figure 22. Another way, shown in Figure 23, is to use a flip-flop to synchronize the $\overline{R D}$ to the LTC1272 with the CLK IN signal. This method will work but has two disavantages
over the first: because the $\overline{\mathrm{RD}}$ is delayed by the flip-flop, the actual conversion start and the enabling of the LTC1272's $\overline{B U S Y}$ and data outputs can take up to one CLK IN cycle to respond to a $\overline{\mathrm{RD}} \downarrow$ convert command from the processor. The sampling of the analog input no longer occurs at the processor's falling $\overline{\mathrm{RD}}$ edge but may be delayed as much as one CLK IN cycle. Although the LTC1272 will still exhibit excellent DC performance, the flip-flop will introduce jitter into the sampling which may reduce the usefulness of this method for AC systems.

## APPLICATIONS INFORMATION

* THE LTC1272 HAS THE SAME OV TO 5V INPUT RANGE BUT PROVIDES A 2.42V REFERENCE OUTPUT AS OPPOSED TO THE -5.25V OF THE AD7572. FOR PROPER OPERATION, REVERSE THE REFERENCE CAPACITOR POLARITY AND SHORT OUT THE $10 \Omega$ RESISTOR.
** THE D FLIP-FLOP SYNCHRONIZES THE CONVERSION START SIGNAL ( $\overline{\mathrm{RD}} \downarrow$ ) TO THE ADC CLKOUT SIGNAL TO PREVENT OUTPUT CODE NOISE WHICH OCCURS WITH AN ASYNCHRONOUS CLOCK.
$\dagger$ THE LTC1272 CAN ACCOMMODATE THE -15V SUPPLY OF THE AD7572 BUT DOES NOT REQUIRE IT. PIN 23 OF THE LTC1272 IS NOT INTERNALLY CONNECTED.

Figure 23. Plugging the LTC1272 into an AD7572 Socket Case 2: Clock Not Synchronous with CS and RD

## PACKAGE DESCRIPTION

N Package
24-Lead PDIP (Narrow . 300 Inch)
(Reference LTC DWG \# 05-08-1510)

SW Package
24-Lead Plastic Small Outline (Wide . 300 Inch)
(Reference LTC DWG \# 05-08-1620)

recommended solder pad layout

Note:
DIMENSIONS IN INCHES
2. DRAWING NOT TO SCALE
3. PIN 1 IDENT, NOTCH ON TOP AND CAVITIES ON THE BOTTOM OF PACKAGES ARE THE MANUFACTURING OPTIONS

THE PART MAY BE SUPPLIED WITH OR WITHOUT ANY OF THE OPTIONS
4. THESE DIMENSIONS DO NOT INCLUDE MOLD FLASH OR PROTRUSIONS

MOLD FLASH OR PROTRUSIONS SHALL NOT EXCEED .006" $(0.15 \mathrm{~mm})$

S24 (WIDE) 0502
