## feATURES

- 250ksps Throughput Rate
- $\pm 2$ LSB INL (Max)
- Guaranteed 16-Bit No Missing Codes
- Low Power: 3.25 mW at $250 \mathrm{ksps}, 13 \mu \mathrm{~W}$ at 1 ksps
- 92dB SNR (typ) at $f_{\mathrm{IN}}=20 \mathrm{kHz}$
- Extended Acquisition Time of $3.25 \mu$ s Allows Use of Lower Power Drivers
- Guaranteed Operation to $125^{\circ} \mathrm{C}$
- 2.5V Supply
- Fully Differential Input Range $\pm 2.5 \mathrm{~V}$
- External 2.5V Reference Input
- No Pipeline Delay, No Cycle Latency
- 1.8 V to 5 V I/O Voltages
- SPI-Compatible Serial I/O with Daisy-Chain Mode
- Internal Conversion Clock
- 16-pin MSOP and $4 \mathrm{~mm} \times 3 \mathrm{~mm}$ DFN Packages

## APPLICATIONS

- Medical Imaging
- High Speed Data Acquisition
- Portable or Compact Instrumentation
- Industrial Process Control
- Low Power Battery-Operated Instrumentation
- ATE

## DESCRIPTIOn

The LTC ${ }^{\circledR 2} 2381-16$ is a low noise, low power, high speed 16-bit successive approximation register (SAR) ADC. Operating from a 2.5 V supply, the LTC2381-16 has a $\pm 2.5 \mathrm{~V}$ fully differential input range. The LTC2381-16 consumes only 3.25 mW and achieves $\pm 2 \mathrm{LSB}$ INL max, no missing codes at 16-bits and 92dB SNR.

The LTC2381-16 has a high speed SPI-compatible serial interface that supports $1.8 \mathrm{~V}, 2.5 \mathrm{~V}, 3.3 \mathrm{~V}$ and 5 V logic while also featuring a daisychain mode. The fast 250 ksps throughput with no cycle latency makes the LTC2381-16 ideally suited for a wide variety of high speed applications. An internal oscillator sets the conversion time, easing external timing considerations. The LTC2381-16 automatically powers down between conversions, leading to reduced power dissipation that scales with the sampling rate.

The LTC2381-16 features a proprietary sampling architecture that enables the ADC to begin acquiring the next sample during the current conversion. The resulting extended acquisition time of $3.25 \mu \mathrm{~s}$ allows the use of extremely low power ADC drivers.

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: All voltage values are with respect to ground.
Note 3: When these pin voltages are taken below ground or above REF or $O V_{D D}$, they will be clamped by internal diodes. This product can handle input currents up to 100 mA below ground or above REF or $\mathrm{OV}_{\mathrm{DD}}$ without latch-up.
Note 4: $\mathrm{V}_{\mathrm{DD}}=2.5 \mathrm{~V}, \mathrm{OV}_{\mathrm{DD}}=2.5 \mathrm{~V}, \mathrm{REF}=2.5 \mathrm{~V}, \mathrm{f}_{\mathrm{SMPL}}=250 \mathrm{kHz}$.
Note 5: Recommended operating conditions.
Note 6: Integral nonlinearity is defined as the deviation of a code from a straight line passing through the actual endpoints of the transfer curve. The deviation is measured from the center of the quantization band.

Note 7: Bipolar zero-scale error is the offset voltage measured from -0.5 LSB when the output code flickers between 0000000000000000 and 1111111111111111 . Full-scale bipolar error is the worst-case of - FS or + FS untrimmed deviation from ideal first and last code transitions and includes the effect of offset error.
Note 8: All specifications in dB are referred to a full-scale $\pm 2.5 \mathrm{~V}$ input with a 2.5 V reference voltage.
Note 9: $f_{\text {SMPL }}=250 \mathrm{kHz}, I_{\text {REF }}$ varies proportionately with sample rate.
Note 10: Guaranteed by design, not subject to test.
Note 11: Parameter tested and guaranteed at $\mathrm{OV}_{\mathrm{DD}}=1.71 \mathrm{~V}, \mathrm{OV}_{\mathrm{DD}}=2.5 \mathrm{~V}$ and $\mathrm{OV}_{\mathrm{DD}}=5.25 \mathrm{~V}$.
Note 12: tsck of 10ns maximum allows a shift clock frequency up to 100 MHz for rising capture.

## PIn fUnCTIOnS

CHAIN (Pin 1): Chain Mode Selector Pin. When low, the LTC2381-16 operates in Normal Mode and the RDL/SDI input pin functions to enable or disable SDO. When high, the LTC2381-16 operates in Chain Mode and the RDL/SDI pin functions as SDI, the daisychain serial data input.
$V_{D D}$ (Pin 2): 2.5V Digital Power Supply. The range of $V_{D D}$ is 2.375 V to 2.625 V . Bypass $\mathrm{V}_{\mathrm{DD}}$ to GND with a $10 \mu \mathrm{~F}$ ceramic capacitor.
GND (Pins 3, 6, 10 and 16): Ground.
$\mathbf{I N}^{+}$, $\mathbf{I N}^{-}$(Pins 4, 5): Positive and Negative Differential Analog Inputs.
REF (Pins 7, 8): Reference Input. The range of REF is 2.4 V to 2.6 V . This pin is referred to the GND pin and should be decoupled closely to the pin with a $47 \mu \mathrm{~F}$ ceramic capacitor (X5R, 0805 size).
CNV (Pin 9): Convert Input. A rising edge on this input initiates a new conversion. When the conversion is done, the part powers down as long as CNV is held high. When CNV is returned low, the part powers up in preparation for the next conversion.

BUSY (Pin 11): BUSY indicator. Goes high at the start of a new conversion and returns low when the conversion has finished.

RDL/SDI (Pin 12): When CHAIN is low, the part is in Normal Mode and the pin is treated as a bus enabling input. When CHAIN is high, the part is in chain mode and the pin is treated as a serial data input pin where data from another ADC in the daisychain is input.
SCK (Pin 13): Serial DataClock Input. When SDO is enabled, the conversion result or daisychain data from another ADC is shifted out on the rising edges of this clock MSB first.

SDO (Pin 14): Serial Data Output. The conversion result or daisychain data is output on this pin on each rising edge of SCK MSB first. The output data is in 2's complement format.

OV ${ }_{\text {DD }}$ (Pin 15): I/O Interface Digital Power. The range of $O V_{D D}$ is 1.71 V to 5.25 V . This supply is nominally set to the same supply as the host interface $(1.8 \mathrm{~V}, 2.5 \mathrm{~V}, 3.3 \mathrm{~V}$, or 5 V ). Bypass $\mathrm{OV}_{\mathrm{DD}}$ to GND with a $0.1 \mu \mathrm{~F}$ capacitor.
GND (Exposed Pad Pin 17 - DFN Package Only): Ground. Exposed pad must be soldered directly to the ground plane.

## Conversion Timing Using the Serial Interface

## APPLICATIONS INFORMATION

## OVERVIEW

The LTC2381-16 is alow noise, low power, high speed 16-bit successive approximation register (SAR) ADC. Operating from a single 2.5 V supply, the LTC2381-16 supports a large $\pm 2.5 \mathrm{~V}$ fully differential input range, making it ideal for high performance applications which require a wide dynamic range. The LTC2381-16 achieves $\pm 2$ LSB INL max, no missing codes at 16-bits and 92dB SNR.
Fast 250ksps throughput with no cycle latency makes the LTC2381-16 ideally suited for a wide variety of high speed applications. An internal oscillator sets the conversion time, easing external timing considerations. The LTC2381-16 dissipates only 3.25 mW at 250 ksps , while an auto power-down feature is provided to further reduce power dissipation during inactive periods.
The LTC2381-16 features a proprietary sampling architecture that enables the ADC to begin acquiring the next sample during the current conversion. The resulting extended acquisition time of $3.25 \mu \mathrm{~s}$ allows the use of extremely low power ADC drivers.

## CONVERTER OPERATION

A rising edge on the CNV pin initiates a conversion. During the conversion phase, the 16-bit CDAC is sequenced through a successive approximation algorithm, effectively comparing the sampled input with binary-weighted fractions of the reference voltage (e.g. $\mathrm{V}_{\text {REF }} / 2, \mathrm{~V}_{\text {REF }} / 4 \ldots$ $V_{\text {REF }} / 65536$ ) using the differential comparator. At the end of conversion, the CDAC output approximates the sampled analog input. The ADC control logic then prepares the 16-bit digital output code for serial transfer.

## TRANSFER FUNCTION

The LTC2381-16 digitizes the full-scale voltage of $2 \times$ REF into $2^{16}$ levels, resulting in an LSB size of $76 \mu \mathrm{~V}$ with $R E F=2.5 \mathrm{~V}$. The ideal transfer function is shown in Figure 2. The output data is in 2's complement format.

## ANALOG INPUT

The analog inputs of the LTC2381-16 are fully differential in order to maximize the signal swing that can be digitized. The analog inputs can be modeled by the equivalent

## APPLICATIONS InFORMATION

circuit shown in Figure 3. The diodes at the input provide ESD protection. In the acquisition phase, each input sees approximately $45 \mathrm{pF}\left(\mathrm{C}_{\text {IN }}\right)$ from the sampling CDAC in series with $40 \Omega\left(R_{0 N}\right)$ from the on-resistance of the sampling switch. Any unwanted signal that is commonto both inputs will be reduced by the common mode rejection of the ADC. The inputs draw a current spike while charging the $\mathrm{C}_{\text {IN }}$ capacitors during acquisition. When the LTC2381-16 is not acquiring the input, the analog inputs draw only a small leakage current.

Figure 2. LTC2381-16 Transfer Function

Figure 3. The Equivalent Circuit for the Differential Analog Input of the LTC2381-16

## INPUT DRIVE CIRCUITS

A low impedance source can directly drive the high impedance inputs of the LTC2381-16 without gain error. A high impedance source should be buffered to minimize settling time during acquisition and to optimize the distortion performance of the ADC. Minimizing settling
time is important even for DC inputs, because the ADC inputs draw a current spike when entering acquisition.

For best performance, a buffer amplifier should be used to drive the analog inputs of the LTC2381-16. The amplifier provides low output impedance which produces fast settling of the analog signal during the acquisition phase. It also provides isolation between the signal source and the current spike the ADC inputs draw.

## Input Filtering

The noise and distortion of the buffer amplifier and signal source must be considered since they add to the ADC noise and distortion. Noisy input signals should be filtered prior to the buffer amplifier input with an appropriate filter to minimize noise. The simple 1-pole RC lowpass filter (LPF1) shown in Figure 4 is sufficient for many applications.
Another filter network consisting of LPF2 and the $100 \Omega$ series input resistors should be used between the buffer and ADC inputs to both minimize the noise contribution of the buffer and to help minimize disturbances reflected into the buffer from sampling transients. Long RC time constants at the analog inputs will slow down the settling of the analog inputs. Therefore, LPF2 requires a wider bandwidth than LPF1. A buffer amplifier with a low noise density must be selected to minimize degradation of the SNR. With the 482 kHz lowpass filter shown in Figure 4, the LT6350 provides the full data sheet performance of the LTC2381-16.

High quality capacitors and resistors should be used in the RC filters since these components can add distortion. NPO and silver mica type dielectric capacitors have excellent linearity. Carbon surface mount resistors can generate distortion from self heating and from damage that may occur during soldering. Metalfilm surface mount resistors are much less susceptible to both problems.

Figure 4. Input Signal Chain

## APPLICATIONS INFORMATION

## Single-Ended-to-Differential Conversion

For single-ended inputsignals, a single-ended to differential conversion circuit must be used to produce a differential signal at the inputs of the LTC2381-16. The LT6350 ADC driver is recommended for performing single-ended-todifferential conversions. The LT6350 is flexible and may be configured to convert single-ended signals of various amplitudes to the $\pm 2.5 \mathrm{~V}$ differential input range of the LTC2381-16. The LT6350 is also available in H-grade to complement the extended temperature operation of the LTC2381-16 up to $125^{\circ} \mathrm{C}$.

Figure 5 shows the LT6350 being used to convert a OV to 2.5 V single-ended input signal. In this case, the first amplifier is configured as a unity gain buffer and the singleended input signal directly drives the high-impedance input of the amplifier. As shown in the FFT of Figure 5a, the LT6350 drives the LTC2381-16 to full datasheet performance without degrading the SNR or THD .
The LT6350 can also be used to buffer and convert single-ended signals larger than the input range of the LTC2381-16 in order to maximize the signal swing that can be digitized. Figure 6 shows the LT6350 converting a $0 \mathrm{~V}-5 \mathrm{~V}$ single-ended input signal to the $\pm 2.5 \mathrm{~V}$ differential input range of the LTC2381-16. In this case, the first amplifier in the LT6350 is configured as an inverting amplifier stage, which acts to attenuate the input signal down to the $0 \mathrm{~V}-2.5 \mathrm{~V}$ input range of the LTC2381-16. In the inverting amplifier configuration, the single-ended input signal source no longer directly drives a high impedance input of the first amplifier. The input impedance is instead set by resistor $R_{\text {IN }}$. $R_{I N}$ must be chosen carefully based on the source impedance of the signal source. Higher values of $R_{\text {IN }}$ tend to degrade both the noise and distortion of the LT6350 and LTC2381-16 as a system. R1, R2 and R3 must be selected in relation to $R_{I N}$ to achieve the desired attenuation and to maintain a balanced input impedance in the first amplifier. Table 1 shows the resulting SNR and THD for several values of $R_{I N}, R 1, R 2$ and R3 in this configuration. Figure 6a shows the resulting FFT when using the LT6350 as shown in Figure 6.

The LT6350 can also be used to buffer and convert large, true bipolar signals which swing below ground to the $\pm 2.5 \mathrm{~V}$ differential input range of the LTC2381-16. Figure 7 shows the LT6350 being used to convert a $\pm 10 \mathrm{~V}$ true bipolar signal for use by the LTC2381-16. The input impedance is again set by resistor $\mathrm{R}_{\mathrm{IN}}$. Table 2 shows the resulting SNR and THD for several values of $R_{\text {IN }}$. Figure 7a shows the resulting FFT when using the LT6350 as shown in Figure 7.

## ADC REFERENCE

The LTC2381-16 requires an external reference to define its input range. A low noise, low temperature drift reference is critical to achieving the full datasheet performance of the ADC. Linear Technology offers a portfolio of high performance references designed to meet the needs of many applications. With its small size, low power and high accuracy, the LTC6652-2.5 is particularly well suited for

use with the LTC2381-16. The LTC6652-2.5 offers 0.05\% (max) initial accuracy and $5 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ (max) temperature coefficient forhigh precision applications. The LTC6652-2.5 is fully specified over the H -grade temperature range and complements the extended temperature operation of the LTC2381-16 up to $125^{\circ} \mathrm{C}$. We recommend bypassing the LTC6652-2.5 with a 47 $\mu$ F ceramic capacitor (X5R, 0805 size) close to the REF pin. All performance curves shown in this datasheet were obtained using the LTC6652-2.5.

## APPLICATIONS InFORMATION

The REF pin of the LTC2381-16 draws charge ( $Q_{\text {CONV }}$ ) from the $47 \mu \mathrm{~F}$ bypass capacitor during each conversion cycle. The reference replenishes this charge with a DC current, $I_{\text {REF }}=Q_{\text {CoNv }} / t_{C Y c}$. The DC current draw of the REF pin, $I_{\text {REF }}$, depends on the sampling rate and output code. If the LTC2381-16 is used to continuously sample a signal at a constant rate, the LTC6652-2.5 will keep the deviation of the reference voltage over the entire code span to less than 0.5LSBs.

When idling, the REF pin on the LTC2381-16 draws only a small leakage current(<1 $\mu \mathrm{A}$ ). In applications where a burst of samples is taken after idling for long periods as shown in Figure $8, \mathrm{I}_{\text {REF }}$ quickly goes from approximately $0 \mu \mathrm{~A}$ to a maximum of $285 \mu \mathrm{~A}$ at 250 ksps . This step in DC current draw triggers a transient response in the reference that must be considered since any deviation in the reference output voltage will affect the accuracy of the output code. In applications where the transient response of the reference is important, the fast settling LTC6655-2.5 reference is recommended. Inserting a $1 \Omega$ resistor between the $47 \mu \mathrm{~F}$ bypass capacitor and reference output as shown in Figure 9 helps to improve the transient settling time and minimize the reference voltage deviation.

## DYNAMIC PERFORMANCE

Fast Fourier Transform (FFT) techniques are used to test the ADC's frequency response, distortion and noise at the rated throughput. By applying a low distortion sine wave and analyzing the digital output using an FFT algorithm, the ADC's spectral content can be examined for frequencies outside the fundamental. The LTC2381-16 provides guaranteed tested limits for both AC distortion and noise measurements.

Figure 9. LTC6655-2.5 Driving REF of LTC2381-16

238116 F10
Figure 10. 32k Point FFT of the LTC2381-16

## Signal-to-Noise and Distortion Ratio (SINAD)

The signal-to-noise and distortion ratio (SINAD) is the ratio between the RMS amplitude of the fundamental input frequency and the RMS amplitude of all other frequency components at the A/D output. The output is band-limited to frequencies from above DC and below half the sampling frequency. Figure 10 shows that the LTC2381-16 achieves a typical SINAD of 92 dB at a 250 kHz sampling rate with a 20kHz input.

Figure 8. CNV Waveform Showing Burst Sampling

## APPLICATIONS InFORMATION

Signal-to-Noise Ratio (SNR)

The signal-to-noise ratio (SNR) is the ratio between the RMS amplitude of the fundamental input frequency and the RMS amplitude of all other frequency components except the first five harmonics and DC. Figure 10 shows that the LTC2381-16 achieves a typical SNR of 92dB at a 250 kHz sampling rate with a 20 kHz input.

## Total Harmonic Distortion (THD)

Total Harmonic Distortion (THD) is the ratio of the RMS sum of all harmonics of the inputsignal to the fundamental itself. The out-of-band harmonics alias into the frequency band between DC and half the sampling frequency ( $f_{S M P L} / 2$ ). THD is expressed as:

$$
T H D=20 \log \frac{\sqrt{V 2^{2}+V 3^{2}+V 4^{2}+\ldots+V_{N}^{2}}}{V 1}
$$

where V 1 is the RMS amplitude of the fundamental frequency and V 2 through $\mathrm{V}_{\mathrm{N}}$ are the amplitudes of the second through Nth harmonics.

## POWER CONSIDERATIONS

The LTC2381-16 provides two power supply pins: the 2.5V power supply ( $\mathrm{V}_{\mathrm{DD}}$ ), and the digital input/output interface power supply ( $O V_{D D}$ ). The flexible $\mathrm{VV}_{D D}$ supply allows the LTC2381-16 to communicate with any digital logic operating between 1.8 V and 5 V , including 2.5 V and 3.3 V systems.

## Power Supply Sequencing

The LTC2381-16 does not have any specific power supply sequencing requirements. Care should be taken to adhere to the maximum voltage relationships described in the Absolute Maximum Ratings section. The LTC2381-16 has a power-on-reset (POR) circuit that will reset the LTC2381-16 at initial power-up or whenever the power supply voltage drops below 1 V . Once the supply voltage reenters the nominal supply voltage range, the POR will reinitialize the ADC. No conversions should be initiated until $20 \mu \mathrm{~s}$ after a POR event to ensure the reinitialization period has ended. Any conversions initiated before this time will produce invalid results.

## TIMING AND CONTROL

## CNV Timing

The LTC2381-16 conversion is controlled by CNV. A rising edge on CNV will start a conversion. Once a conversion has been initiated, it cannot be restarted until the conversion is complete. For optimum performance, CNV should be driven by a clean low jitter signal. Converter status is indicated by the BUSY output which remains high while the conversion is in progress. To ensure that no errors occur in the digitized results, any additional transitions on CNV should occur within 40 ns from the start of the conversion or after the conversion has been completed.

## ACQUISITION

A proprietary sampling architecture allows the LTC2381-16 to begin acquiring the input signal for the next conversion 750 ns after the start of the current conversion. This extends the acquisitiontime to $3.25 \mu \mathrm{~s}$, easing settling requirements and allowing the use of extremely low power ADC drivers. (Refer to the Timing Diagram.)

Figure 11. Power Supply Current of the LTC2381-16 Versus Sampling Rate

## Internal Conversion Clock

The LTC2381-16 has an internal clock that is trimmed to achieve a maximum conversion time of $2.5 \mu \mathrm{~s}$.

## APPLICATIONS INFORMATION

Auto Power-Down

The LTC2381-16 automatically powers down after a conversion has been completed as long as CNV remains high. During power-down, the data from the last conversion can be clocked out. To minimize power dissipation during power-down, disable SDO and turn off SCK. To power up the part, bring CNV Iow at least 200ns (tconvL) before the initiation of the next conversion. The auto power-down feature will reduce the power dissipation of the LTC238116 as the sampling frequency is reduced. Since the time required to power up the part does not change at lower sample rates, the LTC2381-16 can remain powered-down for a larger fraction of the conversion cycle ( $\mathrm{t}_{\mathrm{cyc}}$ ), thereby reducing the average power dissipation which scales linearly with sampling rate as shown in Figure 11.

## DIGITAL INTERFACE

The LTC2381-16 has a serial digital interface. The flexible OV ${ }_{\text {DD }}$ supply allows the LTC2381-16 to communicate with any digital logic operating between 1.8 V and 5 V , including 2.5 V and 3.3 V systems.

The serial output data is clocked out on the SDO pin when an external clock is applied to the SCK pin if SDO is enabled. Clocking out the data after the conversion will yield the best performance. With a shift clock frequency of at least 15 MHz , a 250 ksps throughput is still achieved. The serial output data changes state on the rising edge of SCK and can be captured on the falling edge or next rising edge of SCK. D15 remains valid till the first rising edge of SCK.
The serial interface on the LTC2381-16 is simple and straightforward to use. The following sections describe the operation of the LTC2381-16. Several modes are provided depending on whether a single or multiple ADCs share the SPI bus or are daisy-chained.

15

## LTC2381-16

## TIMING DIAGRAM

Normal Mode, Single Device
When CHAIN $=0$, the LTC2381-16 operates in Normal mode. In Normal mode, RDL/SDI enables or disables the serial data output pin SDO. If RDL/SDI is high, SDO is in high-impedance. If RDL/SDI is low, SDO is driven.

Figure 12 shows a single LTC2381-16 operated in Normal Mode with CHAIN and RDL/SDI tied to ground. With RDL/ SDI grounded, SDO is enabled and the $\operatorname{MSB}(D 15)$ of the new conversion data is available at the falling edge of BUSY. This is the simplest way to operate the LTC2381-16.

Figure 12. Using a Single LTC2381-16 in Normal Mode

## TImInG DIAGRAM

Normal Mode, Multiple Devices
Figure 13 shows multiple LTC2381-16 devices operating in Normal Mode(CHAIN = 0) sharing CNV, SCK and SDO. By sharing CNV, SCK and SDO, the number of required signals to operate multiple ADCs in parallel is reduced. Since SDO is shared, the RDL/SDI input of each ADC must be used to allow only one LTC2381-16 to drive SDO at a
time in order to avoid bus conflicts. As shown in Figure 13, the RDL/SDI inputs idle high and are individually brought low to read data out of each device between conversions. When RDL/SDI is brought low, the MSB of the selected device is output onto SDO. To ensure the MSB is properly output and captured, SCK must be held low at least 1ns before and 16 ns after bringing RDL/SDI low.

Figure 13. Normal Mode with Multiple Devices Sharing CNV, SCK and SDO

## LTC2381-16

## timing dingram

When CHAIN $=0 V_{D D}$, the LTC2381-16 operates in Chain Mode. InChain Mode, SDO is always enabled and RDL/SDI serves as the serial data input pin (SDI) where daisychain data output from another ADC can be input.

This is useful for applications where hardware constraints may limit the number of lines needed to interface to a large number of converters. Figure 14 shows an example with two daisy chained devices. The MSB of converter A will appear at SDO of converter B after 16 SCK cycles. The MSB of converter $A$ is clocked in at the SDI/RDL pin of converter B on the rising edge of the first SCK.

## BOARD LAYOUT

To obtain the best performance from the LTC2381-16 a printed circuit board is recommended. Layout for the printed circuit board (PCB) should ensure the digital and analog signal lines are separated as much as possible. In particular, care should be taken not to run any digital clocks or signals alongside analog signals or underneath the ADC.

Recommended Layout
The following is an example of a recommended PCB layout. A single solid ground plane is used. Bypass capacitors to the supplies are placed as close as possible to the supply pins. Low impedance common returns for these bypass capacitors are essential to the low noise operation of the ADC. The analog input traces are screened by ground. For more details and information refer to DC1571A, the evaluation kit for the LTC2381-16.
