

January 1994

## DESCRIPTION

The SSI 73K222L is a highly integrated single-chip modem IC which provides the functions needed to construct a CCITT V.22, V.21 and Bell 212A compatible modem, capable of 1200 bit/s full-duplex operation over dial-up lines. The SSI 73K222L is an enhancement of the SSI 73K212L single-chip modem which adds V.22 and V.21 modes to the Bell 212A and 103 operation of the SSI 73K212L. In Bell 212A mode, the SSI 73K222L provides the normal Bell 212A and 103 functions and employs a 2225 Hz answer tone. The SSI 73K222L in V.22 mode produces either 550 or 1800 Hz guard tone, recognizes and generates a 2100 Hz answer tone, and allows 600 bit/s V.22 or 0-300 bit/s V.21 operation. The SSI 73K222L integrates analog, digital, and switched-capacitor array functions on a single substrate, offering excellent performance and a high level of functional integration in a single 28- or 22-pin DIP configuration. The SSI 73K222L operates from a single +5V supply.

The SSI 73K222L includes the DPSK and FSK modulator/demodulator functions, call progress and hand-shake tone monitor and a tone generator capable of

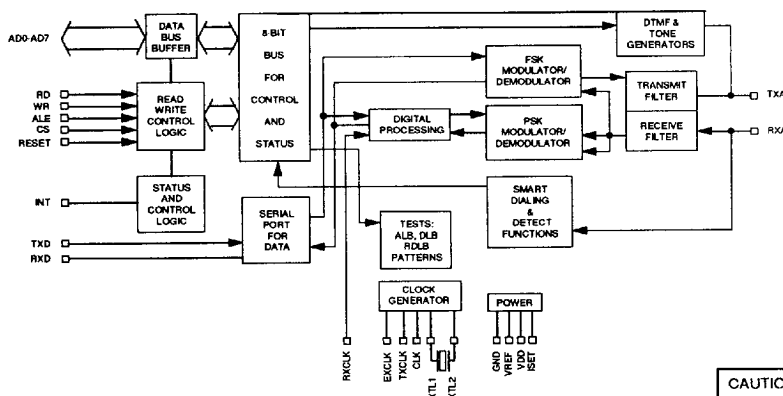

(Continued)

## FEATURES

- One-chip CCITT V.22, V.21, Bell 212A and 103 standard compatible modem data pump
- Full-duplex operation at 0-300 bit/s (FSK) or 600 and 1200 bit/s (DPSK)
- Pin and software compatible with other SSI K-Series 1-chip modems
- Interfaces directly with standard microprocessors (8048, 80C51 typical)
- Serial or parallel microprocessor bus for control
- Serial port for data transfer
- Both synchronous and asynchronous modes of operation including V.22 extended overspeed
- Call progress, carrier, precise answer tone (2100 or 2225 Hz), and long loop detectors
- DTMF, and 550 or 1800 Hz guard tone generators
- Test modes available: ALB, DL, RDL, Mark, Space, Alternating bit patterns
- Precise automatic gain control allows 45 dB dynamic range
- CMOS technology for low power consumption using 30 mW @ 5V
- Single +5 volt supply

## V.22, V.21, Bell 212A

### Single-Chip Modem

#### DESCRIPTION (Continued)

tone required for European applications. This device supports V.22 (except mode v) and V. 21 modes of operation, allowing both synchronous and asynchronous communications. Test features such as analog loop, digital loop, and remote digital loopback are supported. Internal pattern generators are also included for self-testing. The SSI 73K222L is designed to appear to the systems designer as a microprocessor peripheral, and will easily interface with popular one-chip microprocessors (80C51 typical) for control of modem functions through its 8-bit multiplexed address/data bus or serial control bus. An ALE control line simplifies address demultiplexing. Data communications occurs through a separate serial port only.

The SSI 73K222L is ideal for use in either free standing or integral system modem products where full-duplex 1200 bit/s data communications over the 2-wire switched telephone network is desired. Its high functionality, low power consumption and efficient packaging simplify design requirements and increase system reliability. A complete modem requires only the addition of the phone line interface, a control microprocessor, and RS-232 level converter for a typical system. The SSI 73K222L is part of Silicon Systems' K-Series family of pin and function compatible single-chip modem products. These devices allow systems to be configured for higher speeds and Bell or CCITT operation with only a single component change.

#### OPERATION

##### ASYNCHRONOUS MODE

Data transmission for the DPSK mode requires that data ultimately be transmitted in a synchronous fashion. The SSI 73K222L includes ASYNC/SYNC and SYNC/ASYNC converters which delete or insert stop bits in order to transmit data within a  $\pm 0.01\%$  rate. In asynchronous mode the serial data comes from the TXD pin into the ASYNC/SYNC converter. The ASYNC/SYNC converter accepts the data provided on the TXD pin which normally must be 1200 or 600 bit/s  $\pm 1.0\%$ ,  $\pm 2.5\%$ . The converter will then insert or delete stop bits in order to output a signal which is 1200 or 600 bit/s  $\pm 0.01\%$  ( $\pm 0.01\%$  is required synchronous data rate accuracy).

The serial data stream from the ASYNC/SYNC converter is passed through the data scrambler and onto the analog modulator. The data scrambler can be bypassed under processor control when unscrambled data must be transmitted. The ASYNC/SYNC converter and the data scrambler are bypassed in all FSK modes. If serial input data contains a break signal through one character (including start and stop bits) the break will be extended to at least  $2 \cdot N + 3$  bits long (where N is the number of transmitted bits/character).

Serial data from the demodulator is passed first through the data descrambler and then through the SYNC/ASYNC converter. The SYNC/ASYNC converter will reinsert any deleted stop bits and transmit output data at an intra-character rate (bit-to-bit timing) of no greater than 1219 bit/s. An incoming break signal (low through two characters) will be passed through without incorrectly inserting a stop bit.

The SYNC/ASYNC converter also has an extended overspeed mode which allows selection of an overspeed range of either  $+1\%$  or  $+2.3\%$ . In the extended overspeed mode, stop bits are output at 7/8 the normal width.

##### SYNCHRONOUS MODE

The CCITT V.22 standard defines synchronous operation at 600 and 1200 bit/s. The Bell 212A standard defines synchronous operation only at 1200 bit/s. Operation is similar to that of the asynchronous mode except that data must be synchronized to a provided clock and no variation in data transfer rate is allowable. Serial input data appearing at TXD must be valid on the rising edge of TXCLK.

TXCLK is an internally derived signal in internal mode and is connected internally to the RXCLK pin in slave mode. Receive data at the RXD pin is clocked out on the falling edge of RXCLK. The ASYNCH/SYNCH converter is bypassed when synchronous mode is selected and data is transmitted out at the same rate as it is input.

##### DPSK MODULATOR/DEMODULATOR

The SSI 73K222L modulates a serial bit stream into di-bit pairs that are represented by four possible phase shifts as prescribed by the Bell 212A or V.22 standards. The baseband signal is then filtered to reduce intersymbol interference on the bandlimited 2-wire

# SSI 73K222L

## V.22, V.21, Bell 212A

### Single-Chip Modem

telephone line. Transmission occurs using either a 1200 Hz (originate mode) or 2400 Hz carrier (answer mode). Demodulation is the reverse of the modulation process, with the incoming analog signal eventually decoded into di-bits and converted back to a serial bit stream. The demodulator also recovers the clock which was encoded into the analog signal during modulation. Demodulation occurs using either a 1200 Hz carrier (answer mode or ALB originate mode) or a 2400 Hz carrier (originate mode or ALB answer mode). The SSI 73K222L uses a phase locked loop coherent demodulation technique for optimum receiver performance.

#### FSK MODULATOR/DEMODULATOR

The FSK modulator produces a frequency modulated analog output signal using two discrete frequencies to represent the binary data. In Bell 103, the standard frequencies of 1270 and 1070 Hz (originate, mark and space) or 2225 and 2025 Hz (answer, mark and space) are used. V.21 mode uses 980 and 1180 Hz (originate, mark and space), or 1650 and 1850 Hz (answer, mark and space). Demodulation involves detecting the received frequencies and decoding them into the appropriate binary value. The rate converter and scrambler/descrambler are bypassed in the 103 or V.21 modes.

#### PASSBAND FILTERS AND EQUALIZERS

High and low band filters are included to shape the amplitude and phase response of the transmit and receive signals and provide compromise delay equalization and rejection of out-of-band signals in the receive channel. Amplitude and phase equalization are necessary to compensate for distortion of the transmission line and to reduce intersymbol interference in the bandlimited receive signal. The transmit signal filtering approximates a 75% square root of raised Cosine frequency response characteristic.

#### AGC

The automatic gain control maintains a signal level at the input to the demodulators which is constant to within 1 dB. It corrects quickly for increases in signal which would cause clipping and provides a total receiver dynamic range of >45 dB.

#### PARALLEL BUS INTERFACE

Four 8-bit registers are provided for control, option select and status monitoring. These registers are addressed with the AD0, AD1, and AD2 multiplexed address lines (latched by ALE) and appear to a control microprocessor as four consecutive memory locations. Two control registers and the tone register are read/write memory. The detect register is read only and cannot be modified except by modem response to monitored parameters.

#### SERIAL COMMAND INTERFACE

The serial command interface allows access to the SSI 73K222L control and status registers via a serial command port (22-pin version only). In this mode the A0, A1 and A2 lines provide register addresses for data passed through the data pin under control of the  $\overline{RD}$  and  $\overline{WR}$  lines. A read operation is initiated when the  $\overline{RD}$  line is taken low. The first bit is available after  $\overline{RD}$  is brought low and the next seven cycles of EXCLK will then transfer out seven bits of the selected address LSB first. A write takes place by shifting in eight bits of data LSB first for eight consecutive cycles of EXCLK.  $\overline{WR}$  is then pulsed low and data transferred into the addressed register occurs on the rising edge of  $\overline{WR}$ . This interface mode is also supported in the 28-pin packages. See serial control interface pin description.

#### SPECIAL DETECT CIRCUITRY

The special detect circuitry monitors the received analog signal to determine status or presence of carrier, call-progress tones, answer tone and weak received signal (long loop condition). An unscrambled mark request signal is also detected when the received data out of the DPSK demodulator before the descrambler has been high for  $165.5 \text{ ms} \pm 6.5 \text{ ms}$  minimum. The appropriate detect register bit is set when one of these conditions changes and an interrupt is generated for all purposes except long loop. The interrupts are disabled (masked) when the enable interrupt bit is set to 0.

#### DTMF GENERATOR

The DTMF generator will output one of 16 standard tone pairs determined by a 4-bit binary value and TX DTMF mode bit previously loaded into the tone register. Tone generation is initiated when the DTMF mode is selected using the tone register and the transmit enable (CR0 bit D1) is changed from 0 to 1.

# SSI 73K222L

## V.22, V.21, Bell 212A

### Single-Chip Modem

#### PIN DESCRIPTION

##### POWER

NAME	28-PIN	22-PIN	TYPE	DESCRIPTION
GND	28	1	I	System Ground.
VDD	15	11	I	Power supply input, $5V \pm 10\%$ (73K222L). Bypass with .1 and 22 $\mu F$ capacitors to GND.
VREF	26	21	O	An internally generated reference voltage. Bypass with .1 $\mu F$ capacitor to ground.
ISET	24	19	I	Chip current reference. Sets bias current for op-amps. The chip current is set by connecting this pin to VDD through a 2 M $\Omega$ resistor. ISET should be bypassed to GND with a .1 $\mu F$ capacitor.

##### PARALLEL MICROPROCESSOR INTERFACE

ALE	12	-	I	Address latch enable. The falling edge of ALE latches the address on AD0-AD2 and the chip select on $\overline{CS}$ .
AD0-AD7	4-11	-	I/O	Address/data bus. These bidirectional tri-state multiplexed lines carry information to and from the internal registers.
$\overline{CS}$	20	-	I	Chip select. A low on this pin during the falling edge of ALE allows a read cycle or a write cycle to occur. AD0-AD7 will not be driven and no registers will be written if $\overline{CS}$ (latched) is not active. The state of $\overline{CS}$ is latched on the falling edge of ALE.
CLK	1	2	O	Output clock. This pin is selectable under processor control to be either the crystal frequency (for use as a processor clock) or 16 x the data rate for use as a baud rate clock in DPSK modes only. The pin defaults to the crystal frequency on reset.
$\overline{INT}$	17	13	O	Interrupt. This open drain output signal is used to inform the processor that a detect flag has occurred. The processor must then read the detect register to determine which detect triggered the interrupt. $\overline{INT}$ will stay low until the processor reads the detect register or does a full reset.
$\overline{RD}$	14	-	I	Read. A low requests a read of the SSI 73K222L internal registers. Data cannot be output unless both $\overline{RD}$ and the latched $\overline{CS}$ are active or low.
RESET	25	20	I	Reset. An active high signal on this pin will put the chip into an inactive state. All control register bits (CR0, CR1, Tone) will be reset. The output of the CLK pin will be set to the crystal frequency. An internal pull down resistor permits power on reset using a capacitor to VDD.

# SSI 73K222L

## V.22, V.21, Bell 212A

### Single-Chip Modem

#### PIN DESCRIPTION (Continued)

#### PARALLEL MICROPROCESSOR INTERFACE (Continued)

NAME	28-PIN	22-PIN	TYPE	DESCRIPTION
$\overline{WR}$	13	-	I	Write. A low on this informs the SSI 73K222L that data is available on AD0-AD7 for writing into an internal register. Data is latched on the rising edge of $\overline{WR}$ . No data is written unless both $\overline{WR}$ and the latched $\overline{CS}$ are low.

#### SERIAL MICROPROCESSOR INTERFACE

A0-A2	-	5-7	I	Register Address Selection. These lines carry register addresses and should be valid during any read or write operation.
DATA	-	8	I/O	Serial Control Data. Data for a read/write operation is clocked in or out on the falling edge of the EXCLK pin. The direction of data flow is controlled by the $\overline{RD}$ pin. $\overline{RD}$ low outputs data. $\overline{RD}$ high inputs data.
$\overline{RD}$	-	10	I	Read. A low on this input informs the SSI 73K222L that data or status information is being read by the processor. The falling edge of the $\overline{RD}$ signal will initiate a read from the addressed register. The $\overline{RD}$ signal must continue for eight falling edges of EXCLK in order to read all eight bits of the referenced register. Read data is provided LSB first. Data will not be output unless the $\overline{RD}$ signal is active.
$\overline{WR}$	-	9	I	Write. A low on this input informs the SSI 73K222L that data or status information has been shifted in through the DATA pin and is available for writing to an internal register. The normal procedure for a write is to shift in data LSB first on the DATA pin for eight consecutive falling edges of EXCLK and then to pulse $\overline{WR}$ low. Data is written on the rising edge of $\overline{WR}$ .
<p><b>Note:</b> In the serial, 22-pin version, the pins AD0-AD7, ALE and <math>\overline{CS}</math> are removed and replaced with the pins; A0, A1, A2, DATA, and an unconnected pin. Also, the <math>\overline{RD}</math> and <math>\overline{WR}</math> controls are used differently. The serial control mode is provided in the parallel control versions by tying ALE high and <math>\overline{CS}</math> low. In this configuration AD7 becomes DATA and AD0, AD1 and AD2 become A0, A1 and A2, respectively.</p>

## V.22, V.21, Bell 212A

### Single-Chip Modem

#### PIN DESCRIPTION (Continued)

##### DTE USER

NAME	28-PIN	22-PIN	TYPE	DESCRIPTION
EXCLK	19	15	I	External Clock. This signal is used in synchronous transmission when the external timing option has been selected. In the external timing mode the rising edge of EXCLK is used to strobe synchronous DPSK transmit data applied to on the TXD pin. Also used for serial control interface.
RXCLK	23	18	O	Receive Clock. The falling edge of this clock output is coincident with the transitions in the serial received data output. The rising edge of RXCLK can be used to latch the valid output data. RXCLK will be valid as long as a carrier is present.
RXD	22	17	O	Received Data Output. Serial receive data is available on this pin. The data is always valid on the rising edge of RXCLK when in synchronous mode. RXD will output constant marks if no carrier is detected.
TXCLK	18	14	O	Transmit Clock. This signal is used in synchronous transmission to latch serial input data on the TXD pin. Data must be provided so that valid data is available on the rising edge of the TXCLK. The transmit clock is derived from different sources depending upon the synchronization mode selection. In Internal Mode the clock is generated internally. In External Mode TXCLK is phase locked to the EXCLK pin. In Slave Mode TXCLK is phase locked to the RXCLK pin. TXCLK is always active.
TXD	21	16	I	Transmit Data Input. Serial data for transmission is applied on this pin. In synchronous modes, the data must be valid on the rising edge of the TXCLK clock. In asynchronous modes (1200/600 bit/s or 300 baud) no clocking is necessary. DPSK data must be 1200/600 bit/s $\pm 1\%$ , $-2.5\%$ or $\pm 2.3\%$ , $-2.5\%$ in extended overspeed mode.

##### ANALOG INTERFACE AND OSCILLATOR

RXA	27	22	I	Received modulated analog signal input from the telephone line interface.
TXA	16	12	O	Transmit analog output to the telephone line interface.
XTL1 XTL2	2 3	3 4	I I	These pins are for the internal crystal oscillator requiring a 11.0592 MHz parallel mode crystal. Load capacitors should be connected from XTL1 and XTL2 to Ground. XTL2 can also be driven from an external clock.

### Single-Chip Modem

## REGISTER DESCRIPTIONS

Four 8-bit internal registers are accessible for control and status monitoring. The registers are accessed in read or write operations by addressing the A0, A1 and A2 address lines in serial mode, or the AD0, AD1 and AD2 lines in parallel mode. In parallel mode the address lines are latched by ALE. Register CR0 controls the method by which data is transferred over the phone

line. CR1 controls the interface between the microprocessor and the SSI 73K222L internal state. DR is a detect register which provides an indication of monitored modem status conditions. TR, the tone control register, controls the DTMF generator, answer and guard tones and RXD output gate used in the modem initial connect sequence. All registers are read/write except for DR which is read only. Register control and status bits are identified below:

			RECEIVE DATA	UNSCR. MARK	CARR. DETECT	ANSWER TONE	CALL PROG.	LONG LOOP
BIT NO.	NAME		CONDITION	DESCRIPTION				
D2	Answer Tone Detect		0	No answer tone detected.				
			1	Indicates detection of 2225 Hz answer tone in Bell mode or 2100 Hz in CCITT mode. The device must be in originate mode for detection of answer tone. For CCITT answer tone detection, bit D0 of the Tone Register must be set to a 1.				
D3	Carrier Detect		0	No carrier detected in the receive channel.				
			1	Indicates carrier has been detected in the receive channel.				
D4	Unscrambled Mark Detect		0	No unscrambled mark.				
			1	Indicates detection of unscrambled marks in the received data. A valid indication requires that unscrambled marks be received for $> 165.5 \pm 6.5$ ms.				
D5	Receive Data			Continuously outputs the received data stream. This data is the same as that output on the RXD pin, but it is not disabled when RXD is tri-stated.				
D6, D7				Not used.

### Single-Chip Modem

#### DIRECT ACCESS ARRANGEMENT (DAA)

The telephone line interfaces show two examples of how the "hybrid" may be implemented. The split supply design (Figure 1) is a typical two op-amp hybrid. The receive op-amp serves two purposes. It supplies gain to amplify the receive signal to the proper level for the modem's detectors and demodulator, and it removes the transmitted signal from the receive signal present at the transformer. This is done by supplying a portion of the transmitted signal to the non-inverting input of the receive op-amp at the same amplitude as the signal appearing at the transformer, making the transmit signal common mode.

The single-supply hybrid is more complex than the dual-supply version described above, but its use eliminates the need for a second power supply. This circuit (Figure 2) uses a bridged drive to allow undistorted signals to be sent with a single 5V supply. Because DTMF tones utilize a higher amplitude than data, these

signals will clip if a single-ended drive approach is used. The bridged driver uses an extra op-amp (U1A) to invert the signal coming from the gain setting op-amp (U1B) before sending it to the other leg of the transformer. Each op-amp then supplies half the drive signal to the transformer. The receive amplifier (U1C) picks off its signal at the junction of the impedance matching resistor and the transformer. Because the bottom leg of the transformer is being driven in one direction by U1A and the resistor is driven in the opposite direction at the same time by U1B, the junction of the transformer and resistor remains relatively constant and the receive signal is unaffected.

#### DESIGN CONSIDERATIONS

Silicon Systems' 1-chip modem products include all basic modem functions. This makes these devices adaptable for use in a variety of applications, and as easy to control as conventional digital bus peripherals.

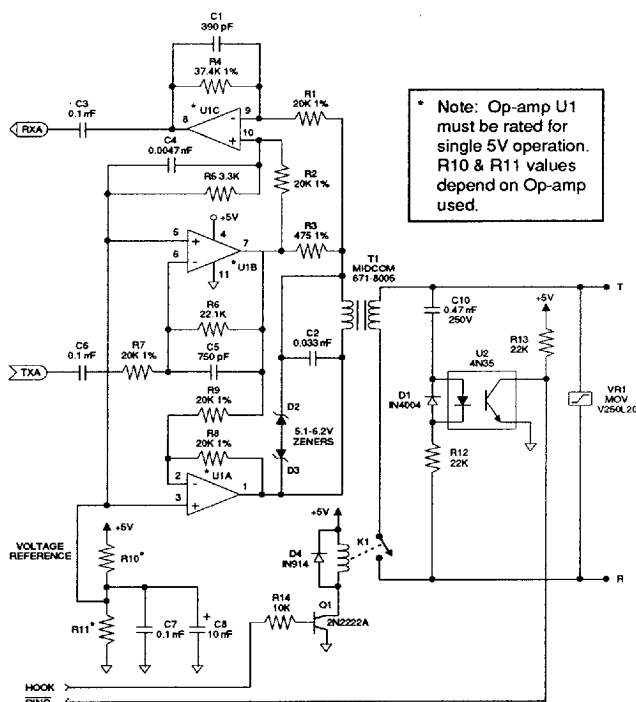

FIGURE 2: Single 5V Hybrid Version

Unlike digital logic circuitry, modem designs must properly contend with precise frequency tolerances and very low level analog signals, to ensure acceptable performance. Using good analog circuit design practices will generally result in a sound design. Following are additional recommendations which should be taken into consideration when starting new designs.

#### CRYSTAL OSCILLATOR

The K-Series crystal oscillator requires a parallel mode (antiresonant) crystal which operates at 11.0592 MHz. It is important that this frequency be maintained to within  $\pm 0.01\%$  accuracy.

In order for a parallel mode crystal to operate correctly and to specification, it must have a load capacitor connected to the junction of each of the crystal and internal inverter connections, terminated to ground. The values of these capacitors depend primarily on the crystal's characteristics, and to a lesser degree on the internal inverter circuit. The values used affect the accuracy and start up characteristics of the oscillator.

#### LAYOUT CONSIDERATIONS

Good analog/digital design rules must be used to control system noise in order to obtain highest performance in modem designs. The more digital circuitry present on the PC board, the more this attention to noise control is needed. The modem should be treated as a high impedance analog device. A 22 mF electrolytic capacitor in parallel with a 0.1 mF ceramic capacitor between VDD and GND is recommended. Liberal use of ground planes and larger traces on power and ground are also highly favored. High speed digital circuits tend to generate a significant amount of EMI (Electro-Magnetic Interference) which must be minimized in order to meet regulatory agency limitations. To accomplish this, high speed digital devices should be locally bypassed, and the telephone line interface and K-Series device should be located close to each other near the area of the board where the phone line connection is accessed. To avoid problems, power supply and ground traces should be routed separately to the analog and digital functions on the board, and digital signals should not be routed near low level or high impedance analog traces. The analog and digital grounds should only connect at one point near the K-Series device ground pin to avoid ground loops. The K-Series modem IC's should have both high frequency and low frequency bypassing as close to the package as possible.

#### MODEM PERFORMANCE CHARACTERISTICS

The curves presented here define modem IC performance under a variety of line conditions while inducing disturbances that are typical of those encountered during data transmission on public service telephone lines. Test data was taken using an AEA Electronics' "Autotest I" modem test set and line simulator, operating under computer control. All tests were run full-duplex, using a Concord Data Systems 224 as the reference modem. A 511 pseudo-random-bit pattern was used for each data point. Noise was C-message weighted and all signal-to-noise (S/N) ratios reflect total power measurements similar to the CCITT V.56 measurement specification. The individual tests are defined as follows.

##### BER vs. S/N

This test measures the ability of the modem to operate over noisy lines with a minimum of data-transfer errors. Since some noise is generated in the best of dial-up lines, the modem must operate with the lowest S/N ratio possible. Better modem performance is indicated by test curves that are closest to the BER axis. A narrow spread between curves representing the four line parameters indicates minimal variation in performance while operating over a range of aberrant operating conditions. Typically, a DPSK modem will exhibit better BER-performance test curves receiving in the low band than in the high band.

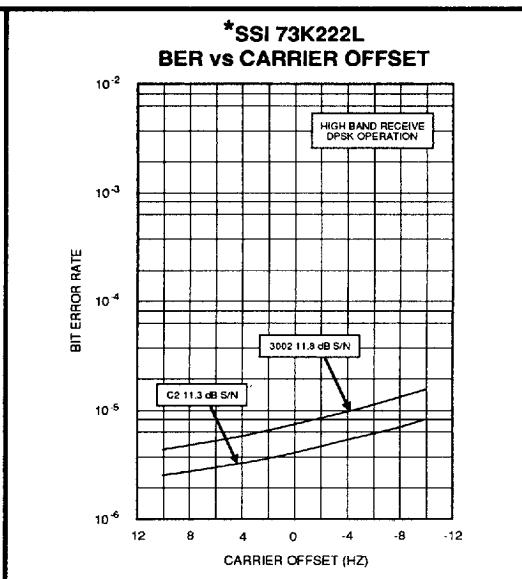

##### BER vs. Receive Level

This test measures the dynamic range of the modem. Because signal levels vary widely over dial-up lines, the widest possible dynamic range is desirable. The minimum Bell specification calls for 36 dB of dynamic range. S/N ratios are held constant at the indicated values while the receive level is lowered from a very high to very low signal levels. The width of the "bowl" of these curves, taken at the BER point, is the measure of dynamic range.
