

M58LW064A M58LW064B

64 Mbit (x16 and x16/x32, Block Erase) Low Voltage Flash Memories

PRODUCT PREVIEW

- M58LW064A x16 organisation,
- M58LW064B x16/x32 selectable
- MULTI-BIT CELL for HIGH DENSITY and LOW COST
- SUPPLY VOLTAGE
 - V_{DD} = 2.7V to 3.6V Supply Voltage
 - V_{DDQ} = 2.7V to 3.6V or 1.8V to 2.5V Input/Output Supply Voltage
- PIPELINED SYNCHRONOUS BURST INTERFACE
- SYNCHRONOUS/ASYNCHRONOUS READ
 - Synchronous Burst read
 - Asynchronous Random and Latch Enabled Controlled Read, with Page Read
- ACCESS TIME
 - Synchronous Burst Read up to 66MHz
 - Asynchronous Page Mode Read 150/25ns, Random Read 150ns
- PROGRAMMING TIME
 - 16 Word or 8 Double-Word Write Buffer
 - 12us Word effective programming time
- MEMORY BLOCKS
 - 64 Equal blocks of 1 Mbit
- ELECTRONIC SIGNATURE
 - Manufacturer Code: 20h
 - Device Code M58LW064A: 17h
 - Device Code M58LW064B: 14h

DESCRIPTION

The M58LW064 is a non-volatile Flash memory that may be erased electrically at the block level and programmed in-system on a 16 Word or 8 Double-Word basis using a 2.7V to 3.6V supply for the circuit and a supply down to 1.8V for the Input and Output buffers. The M58LW064A is organised as 4M by 16 bit. The M58LW064B has 4M by 16 bit or 2M by 32 bit organisation selectable by the Word Organisation \overline{WORD} input. Both devices are internally configured as 64 blocks of 1 Mbit each.

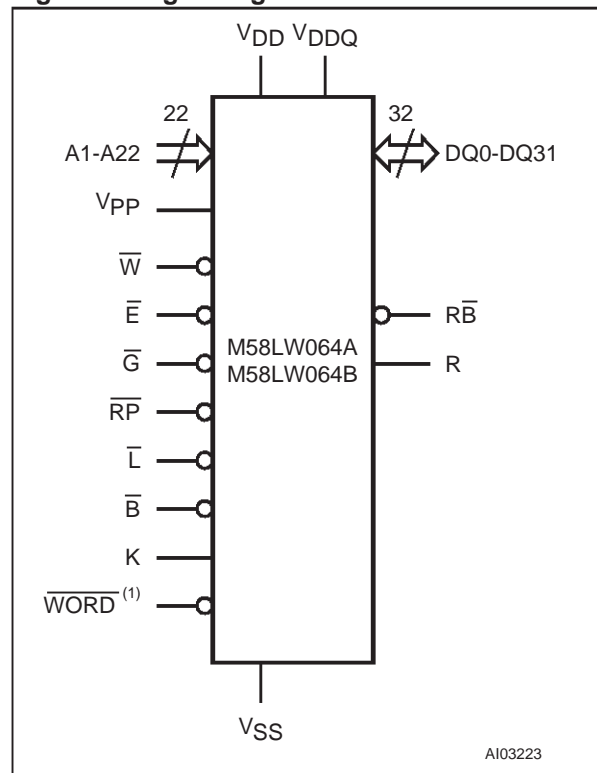

Figure 1. Logic Diagram

Note: 1. Only on M58LW064B.

Table 1. Signal Names

A1-A22	Address Inputs x16 Organisation
A2-A22	Address inputs x32 Organisation
DQ0-DQ7	Data Input/Output x16 and x32 Organisation Command Input, Electronic Signature Output, Block Protection Status Output, Status Register Output
DQ8-DQ15	Data Input/Output x16 and x32 Organisation
DQ16-DQ31	Data Input/Output x32 Organisation
\overline{B}	Burst Address Advance
\overline{E}	Chip Enable
\overline{G}	Output Enable
K	Burst Clock
\overline{L}	Latch Enable
R	Valid Data Ready (open drain output)
\overline{RB}	Ready/Busy (open drain output)
\overline{RP}	Reset/Power-down
V _{PP}	Program/Erase Enable
\overline{W}	Write Enable
\overline{WORD}	Word Organisation (M58LW064B only)
V _{DD}	Supply Voltage
V _{DDQ}	Input/Output Supply Voltage
V _{SS}	Ground
NC	No internal connection
DU	Don't Use (internally connected)

The devices support Asynchronous Random and Latch Enable Controlled Read with Page mode as well as Synchronous Burst Read with a configurable burst. They also support pipelined synchronous Burst Read. Writing is Asynchronous or Asynchronous Latch Enable Controlled.

The configurable synchronous burst read interface allows a high data transfer rate controlled by the

Burst Clock K signal. It is capable of bursting fixed or unlimited lengths of data. The burst type, latency and length are configurable and can be easily adapted to a large variety of system clock frequencies and microprocessors. A 16 Word or 8 Double-Word Write Buffer improves effective programming speed by up to 20 times when data is programmed in full buffer increments. Effective Word programming takes typically 12µs. The array matrix organisation allows each block to be erased and reprogrammed without affecting other blocks. Program and Erase operations can be suspended in order to perform either Read or Program in any other block and then resumed. All blocks are protected against spurious programming and erase cycles at power-up. Any block can be separately protected at any time. The block protection bits can also be deleted, this is executed as one sequence for all blocks simultaneously. Block protection can be temporarily disabled. Each block can be programmed and erased over 100,000 cycles. Block erase is performed in typically 1 second.

An internal Command Interface (C.I.) decodes Instructions to access/modify the memory content. The Program/Erase Controller (P/E.C.) automatically executes the algorithms taking care of the timings required by the program and erase operations. Verification is internally performed and a Status Register tracks the status of the operations. The Ready/Busy output \overline{RB} indicates the completion of operations.

Instructions are written to the memory through the Command Interface (C.I.) using standard microprocessor write timings. The device supports the Common Flash Interface (CFI) command set definition.

A Reset/Power-down mode is entered when the \overline{RP} input is Low. In this mode the power consumption is lower than in the normal standby mode, the device is write protected and both the Status and the Burst Configuration Registers are cleared. A recovery time is required when the \overline{RP} input goes High.

The device is offered in various package versions, TSOP56 (14 x 20 mm), TSOP86 Type II (11.76 x 22.22 mm) and LPGA54 1mm ball pitch for the M58LW064A and PQFP80 for the M58LW064B.

Table 2. Absolute Maximum Ratings (1)

Symbol	Parameter		Value	Unit
T _A	Ambient Operating Temperature	Grade 1	0 to 70	°C
		Grade 6	-40 to 85	
T _{BIAS}	Temperature Under Bias		-40 to 125	°C
T _{STG}	Storage Temperature		-55 to 150	°C
V _{IO}	Input or Output Voltage		-0.6 to V _{DDQ} +0.6	V
V _{DD} , V _{DDQ}	Supply Voltage		-0.6 to 5.0	V
V _{HH}	\overline{RP} Hardware Block Unlock Voltage		-0.6 to 10 ⁽²⁾	V

Note: 1. Except for the rating "Operating Temperature Range", stresses above those listed in the Table "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the Operating sections of this specification is not implied. Exposure to Absolute Maximum Rating conditions for extended periods may affect device reliability. Refer also to the STMicroelectronics SURE Program and other relevant quality documents.

2. Cumulative time at a high voltage level of 10V should not exceed 80 hours on \overline{RP} pin.

Figure 6. Memory Map

ORGANISATION

Memory control is provided by Chip Enable \bar{E} , Output Enable \bar{G} and Write Enable \bar{W} inputs. A Latch Enable \bar{L} input latches an address for both Read and Write operations. The Burst Clock \bar{K} and the Burst Address Advance \bar{B} inputs synchronize the memory to the microprocessor during burst read. Reset/Power-down \bar{RP} is used to reset all the memory circuitry, excluding the block protection bits, and to set the chip in deep power down mode. Erase and Program operations are controlled by an internal Program/Erase Controller (P/E.C.). A Status Register data output on DQ7 provides a Ready/Busy signal to indicate the state of the P/E.C. operations. A Ready/Busy \bar{RB} output also indicates the completion of the internal algorithms. A Valid Data Ready \bar{R} output indicates the memory data output valid status during the synchronous burst mode operations.

A Word Organisation \bar{WORD} input selects the x16 or x32 data width for the M58LW064B. For the x16 only organisation of the M58LW064A or the x16 organisation of the M58LW064B the address lines are A1-A22 and the Data Input/Output is on DQ0-DQ15. For the x32 organisation of the M58LW064B the address lines are A2-A22 and the Data Input/Output is DQ0-DQ31.

MEMORY BLOCKS

The device has a uniform block architecture with an array of 64 separate blocks of 1Mbit each. The memory features a software erase suspend of a block allowing read or programming within any other block. A suspended erase operation can be resumed to complete block erasure. A program suspend operation on a block allows reading only within any other block. A suspend program operation can be resumed to complete programming. At any moment of the sequence the Status Register indicates the status of the operation.

Each block is erased separately. An Erase or Program operation is managed automatically by the P/E.C. Individual block protection against Program or Erase provides additional data security. All blocks are protected during power-up. A software instruction is provided to cancel all block protection bits simultaneously in an application and a higher level input on \bar{RP} can temporarily disable the protection mechanism. A software instruction is provided to allow protection of some or all of the blocks in an application. All Program or Erase operations are blocked when the Program/Erase Enable input V_{PP} is Low.

BUS OPERATIONS

The following operations can be performed using the appropriate bus configuration:

Asynchronous

- Read Array
- Read Electronic Signature
- Read Block Protection
- Read Status Register
- Read Query
- Write
- Output Disable
- Standby
- Reset/Power-down

Synchronous

- Address Latch
- Burst Read
- Burst Read Suspend
- Burst Read Interrupt
- Burst Read Resume
- Burst Address Advance

See Tables 3, 4, 5, 6 and 7.

COMMAND INTERFACE

Instructions, made up of Commands written in Cycles, can be given to the Program/Erase Controller (P/E.C.) by writing to the Command Interface (C.I.). At power-up or on exit from power down or if V_{DD} is lower than V_{LKO} , the Command Interface is reset to Read Array. Any incorrect command will reset the device to Read Array. Any improper command sequence will cause the Status Register to report the error condition and the device will default to Read Status Register.

The internal Program/Erase Controller (P/E.C.) automatically handles all timing and verification of the Program and Erase operations. The Status Register information P/ECS on DQ7 can be read at any time, during programming or erase, to monitor the progress of the operation.

Table 3. Asynchronous Bus Operations (1)

Operation	\bar{E}	\bar{G}	\bar{W}	\bar{RP}	\bar{L}	DQ0-DQ31
Read Array	V_{IL}	V_{IL}	V_{IH}	High	X	Data Output
Read Electronic Signature or Block Protection Status	V_{IL}	V_{IL}	V_{IH}	High	X	Manufacturer or Device Code Output Block Protection Status
Read Status P/E.C. Active	V_{IL}	V_{IL}	V_{IH}	High	X	Status Register Output

SIGNAL DESCRIPTIONS

See Figure 1 and Table 1.

Address Inputs (A1-A22). A1 is used to select between the high and low Word in the x16 configuration of the M58LW064A or B. For the M58LW064B A1 is not used in the x32 mode.

When Chip Enable \bar{E} is at V_{IL} the address bus is used to input addresses for the memory array in Read mode, or addresses for the data to be programmed, or to input addresses associated with Commands to be written to the Command Interface. The address latch is transparent when Latch Enable \bar{L} is at V_{IL} . The address inputs for the memory array are latched on the rising edge of Chip Enable \bar{E} or Latch Enable \bar{L} or Write Enable \bar{W} , whichever occurs first in a write operation. The address is also internally latched in the command for an Erase or Program Instruction.

Data Inputs/Outputs (DQ0-DQ31). Input data for a Write to Buffer and Program operation and for writing Commands to the Command Interface are latched on the rising edge of Write Enable \bar{W} or Chip Enable \bar{E} , whichever occurs first.

When Chip Enable \bar{E} and Output Enable \bar{G} are at V_{IL} data is output from the Array, the Electronic Signature - the Manufacturer and the Device code - the Block Protection status, the CFI Query information or the Status Register. The data bus is high impedance when the device is deselected with Chip Enable \bar{E} at V_{IH} , Output Enable \bar{G} is at V_{IH} or \bar{RP} is at V_{IL} . When the P/E.C. is active the Status Register content is output on DQ0-DQ7 and DQ8-DQ31 are at V_{IL} .

Chip Enable (\bar{E}). The Chip Enable \bar{E} input activates the memory control logic, input buffers, decoders and sense amplifiers. Chip Enable \bar{E} at V_{IH} deselected the memory and reduces the power consumption to the standby level.

Output Enable (\bar{G}). The Output Enable \bar{G} gates the outputs through the data output buffers during a read operation. When Output Enable \bar{G} is at V_{IH} the outputs are high impedance. Output Enable \bar{G} can be used to suspend the data output in a burst read operation.

Write Enable (\bar{W}). The Write Enable \bar{W} input controls writing to the Command Interface, Input Address and Data latches. Both addresses and data are latched on the rising edge of \bar{W} (see also Latch Enable \bar{L}).

Reset/Power-down (\bar{RP}). The Reset/Power-down \bar{RP} input provides a hardware reset of the memory and power-down functions. Reset/Power-down of the memory is achieved by pulling \bar{RP} to V_{IL} for at least t_{PLPH} . Writing is inhibited to protect data, the Command Interface and the P/E.C. are reset. The Status Register information is cleared and power consumption is reduced to deep power-down level. The device acts as deselected, that is the data outputs are high impedance.

When \bar{RP} rises to V_{IH} , the device will be available for new operations after a delay of t_{PHQV} and will be configured by default for Asynchronous Random Read. The minimum delay required to access the Command Interface by a write cycle is t_{PHWL} .

If the \bar{RP} input is activated during a Block Erase, a Write to Buffer and Program or a Block Protect/Unprotect operation the cycle is aborted and data is altered and may be corrupted. The Ready/Busy output \bar{RB} may remain low for a maximum time of $t_{PLPH} + t_{PHRH}$ beyond the completion of the Reset/Power-down \bar{RP} pulse.

Applying the higher voltage V_{HH} to the Reset/Power-down input \bar{RP} temporarily unprotects and enables Erase and Program operations on all blocks. Thus it acts as a hardware block unprotect input.

In an application, it is recommended to associate \bar{RP} to the reset signal of the microprocessor. Otherwise, if a reset operation occurs while the device is performing an Erase or Program cycle, the Flash memory may output the Status Register information instead of being re-initialized to the default Asynchronous Random Read.

Latch Enable (\bar{L}). Latch Enable \bar{L} latches the address bits A1-A22 on its rising edge for the Asynchronous Latch Enable Controlled Read or Write, or Synchronous Burst Read operations. The address latch is transparent when Latch Enable \bar{L} is at V_{IL} . Latch Enable \bar{L} must remain at V_{IL} for Asynchronous Random Read and Write operations.

Burst Clock (K). The Burst Clock K is used only in burst mode. It is the fundamental synchronous signal that allows internal latching of the address from the address bus, together with Latch Enable \bar{L} ; increment of the internal address counter in association with Burst Address Advance \bar{B} ; and to indicate valid data on the external data bus. All these operations are synchronously controlled on the valid edge of the Burst Clock K, which can be selected to be the rising or falling edge depending on the definition in the Burst Configuration Register.

For Asynchronous Read or Write, the Burst Clock K input level is Don't Care. For Synchronous Burst Read the address is latched on the first valid clock edge when Latch Enable \bar{L} is at V_{IL} , or the rising edge of Latch Enable \bar{L} , whichever occurs first.

Burst Address Advance (\bar{B}). Burst Address Advance \bar{B} enables increment of the internal address counter when it falls to V_{IL} during Synchronous Burst Read. It is sampled on the last valid edge of the Burst Clock K at the expiry of the X-latency time. If sampled at V_{IL} , new data will be output on the next Burst Clock K valid edge (or second next depending on the definition in the Burst Configuration Register). If it is at V_{IH} when sampled, the previous data remains on the Data Outputs. The Burst Address Advance \bar{B} may be tied to V_{IL} .

Ready (R). The Valid Data Ready R is an output signal used during Synchronous Burst Read. It indicates, at the valid clock edge (or one cycle before depending on the definition in the Burst Configuration Register), if valid data is ready on the Data Outputs. New Data Outputs are valid if Valid Data Ready R is at V_{IH} , the previous Data Outputs remain active if Valid Data Ready R is at V_{IL} .

In all operations except Burst Read, Valid Data Ready R is at V_{IH} . It may be tied to other components with the same Valid Data Ready R signal to create a unique system Ready signal. The Valid Data Ready R output has an internal pull-up resistor of around 1 M Ω powered from V_{DDQ} , designers

should use an external pull-up resistor of the correct value to meet the external timing requirements for R going to V_{IH} .

Word Organisation (\bar{WORD}). The Word Organisation \bar{WORD} input is present only on the M58LW064B and selects x16 or x32 organisation. The \bar{WORD} input selects the data width as Word wide (x16) or Double-Word wide (x32). When \bar{WORD} is at V_{IL} , Word-wide x16 width is selected and data is read and programmed on DQ0-DQ15, DQ16-DQ31 are at high impedance and A1 is the LSB address. When \bar{WORD} is at V_{IH} , the Double-Word wide x32 width is selected and the data is read and programmed on DQ0-DQ31, and A2 is the LSB address.

Ready/Busy (\bar{RB}). Ready/Busy \bar{RB} is an open-drain output and gives the internal state of the P/E.C. When Ready/Busy \bar{RB} is at V_{IL} the device is busy with a Program or Erase operation and it will not accept any additional program or erase instructions except for the Program or Erase Suspend instructions. When a Program or Erase Suspend is given the \bar{RB} signal rises to V_{IH} , after a latency time, to indicate that the Command Interface is ready for a new instruction. When \bar{RB} is at V_{IH} , the device is ready for any Read, Program or Erase operation. Ready/Busy \bar{RB} is also at V_{IH} when the memory is in Erase/Program Suspend or Standby modes.

Program/Erase Enable (V_{PP}). Program/Erase Enable V_{PP} automatically protects all blocks from programming or erasure when at V_{IL} .

Supply Voltage (V_{DD}). The Supply Voltage V_{DD} is the main power supply for all operations (Read, Program and Erase).

Input/Output Supply Voltage (V_{DDQ}). The Input/Output Supply Voltage V_{DDQ} is the Input and Output buffer power supply for all operations (Read, Program and Erase).

Ground (V_{SS}). Ground V_{SS} is the reference for all the voltage measurements.

DEVICE OPERATIONS

See Tables 5, 6, 7 and 10.

Address Latch. An address is latched on the rising edge of the Latch Enable \bar{L} input for Asynchronous Latch Enable Controlled Read. For Asynchronous Latch Enable Controlled Write, the address is latched on the rising edge of Chip Enable \bar{E} , Write Enable \bar{W} or Latch Enable \bar{L} , whichever occurs first.

For Synchronous Burst Read the address is latched on the first valid Burst Clock K edge when Latch Enable \bar{L} is at Low, or on the rising edge of Latch Enable \bar{L} , whichever occurs first.

Asynchronous Random Read. Asynchronous Random Read outputs the contents of the Array. Both Chip Enable \bar{E} and Output Enable \bar{G} must be Low in order to read the output of the memory.

By first writing the appropriate Instruction, the Electronic Signature (RSIG), the Status Register (RSR), the Read Query Instruction (RCFI) or the Block Protection Status (RSIG) can be read.

Asynchronous Random Read is the default read mode which the device enters on power-up or on return from Reset/Power-down.

Asynchronous Page Read. Asynchronous Page Read may be used for Random or Latch Enable Controlled Reads of the Array, which are performed independent of the Burst Clock signal. A page has a size of 4 Words or 2 Double-Words and is addressed by the address inputs A1 and A2 in the x16, or A2 only in the x32 organisation. Data is read internally and stored in the Page Buffer. The page read starts when both Chip Enable \bar{E} and Output Enable \bar{G} are Low. The first data is internally read and is output after the normal access time t_{AVQV} . Successive Words or Double-Words can be read with a much reduced access time of t_{AVQV1} by changing only the low address bits.

Synchronous Burst Read. The memory supports different types of burst access using a Burst Configuration Register to configure the burst type, length and latency.

In continuous burst read, one burst read operation can access the entire memory sequentially by keeping the Burst Address Advance B Low for the appropriate number of clock cycles. At the end of the memory address space the burst read restarts from the beginning at address 000000h.

Synchronous Burst Read is activated when the Burst Clock K input is clocking and Chip Enable \bar{E} is Low. The burst start address is latched and loaded into the internal Burst Address Counter on the valid Burst Clock K edge (rising or falling depending on the M6 bit value for the Burst Clock Edge Configuration in the Burst Configuration Register) when Latch Enable \bar{L} is Low, or upon the rising edge of Latch Enable \bar{L} when the Burst

Clock K is valid. After an initial memory latency time, the memory outputs data each clock cycle (or two clock cycles depending on M9 bit value defined in the Burst Configuration Register). The Burst Address Advance B input controls the memory burst output. The second burst output is on the next clock valid edge after the Burst Address Advance B has been pulled Low.

The Valid Data Ready output signal R monitors if the memory burst boundary is exceeded and the Burst Controller of the microprocessor needs to insert wait states. When Valid Data Ready R is Low on the active clock edge, no new data is available and the memory does not increment the internal address counter at the active clock edge even if Burst Address Advance B is Low.

Synchronous Burst Read will be suspended when Burst Address Advance B is High. The Valid Data Ready signal R may be configured (by bit M8 of Burst Configuration Register) to be valid immediately at the valid clock edge or one data cycle before the valid clock edge.

To increase the data throughput the device has been built with an internal pipelined architecture allowing the user to enter a burst read input command and the next starting address location to be read while the device is filling the output data bus with its current burst content. This pipelined structure is intended to produce no wait-states on the output data bus for successive burst read mode operations.

Asynchronous and Latch Enable Controlled Write. Asynchronous Write is used to give commands to the Command Interface for Instructions to the memory or to latch addresses and input data to be programmed. To perform any Instruction the Command Interface is activated starting with a write cycle. A write cycle is also required give the Instruction to clear the Status Register information. Two write cycles are needed to define the Block Erase and the Write to Buffer and Program Instructions. The first write cycle defines the Instruction selection and the second indicates the appropriate block address to be erased for the Block Erase instruction, or the address locations to program with the number of Words or Double-Words in the Write to Buffer and Program Instruction.

An Asynchronous Write is initiated when Chip Enable \bar{E} , Write Enable \bar{W} and Latch Enable \bar{L} are Low with Output Enable \bar{G} High. Commands and Input Data are latched on the rising edge of Chip Enable \bar{E} or Write Enable \bar{W} , whichever occurs first. For an Asynchronous Latch Enable Controlled Write the address is latched on the rising edge of Latch Enable \bar{L} , Write Enable \bar{W} or Chip Enable \bar{E} , whichever occurs first.

Data to be programmed in the array is internally latched in the Write Buffer before the programming operation starts and a minimum of 4 Words or 2 Double-Words need to be programmed in the same sequence and must be contained in the same address location boundary defined by A1 to A2 for the x16 and A2 for the x32 organisation. Write operations are asynchronous and the Burst Clock signal K is ignored during a write operation.

Output Disable. The data outputs are high impedance when the Output Enable \overline{G} is High.

Standby. The memory is in standby when Chip Enable \overline{E} goes High and the P/E.C. is idle. The power consumption is reduced to the standby level and the outputs are high impedance, independent of the Output Enable \overline{G} or Write Enable \overline{W} inputs.

Automatic Low Power. After a short time of bus inactivity (no Chip Enable \overline{E} , Latch Enable \overline{L} or Address transitions) the chip automatically enters a pseudo-standby mode where consumption is reduced to the Automatic Low Power standby value, while the outputs may still drive the bus. The Automatic Low Power feature is available only for Asynchronous Read.

Power-down. The memory is in Power-down when Reset/Power-down \overline{RP} is Low. The power consumption is reduced to the power-down level and the outputs are high impedance, independent of the Chip Enable \overline{E} , Output Enable \overline{G} or Write Enable \overline{W} inputs.

Electronic Signature. Two codes identifying the manufacturer and the device can be read from the memory allowing programming equipment or applications to automatically match their interface to the characteristics of the memory. The Electronic Signature is output by giving the RSIG Instruction. The manufacturer code is output when all the Address inputs are Low. The device code is output when A1 (M58LW064A) or A2 (M58LW064B) input is High, the other pins A3-A22 must be Low. The codes are output on DQ0-DQ7. A return to Read mode is achieved by writing the Read Array instruction.

INITIALIZATION

The device must be powered up and initialized in a predefined manner. Procedures other than specified may result in undefined operation.

Power should be applied simultaneously to V_{DD} and V_{DDQ} with the \overline{RP} input held Low. When the supplies are stable \overline{RP} is taken High. The Output Enable \overline{G} , Chip Enable \overline{E} and Write Enable \overline{W} inputs should also be held High during power-up. The memory will be ready to accept the first Instruction after the power-up time t_{PUR} . The device is automatically configured for Asynchronous Random Read at power-up or after leaving Reset/Power-down.

BURST CONFIGURATION REGISTER

See Tables 8, 9, 10 and 11.

The Synchronous Burst Read, Asynchronous Random Read, Asynchronous Latch Enable Controlled Read are selected using the Burst Configuration Register.

For Synchronous Read the register defines the X and Y Latencies, Valid Data Ready signal timing, Burst Type, Valid Clock Edge and Burst Length. The Burst Configuration Register is programmed using the Set Burst Configuration Register (SBCR) Instruction and will retain the stored information until it is programmed again or the device is reset or goes into the Reset/Power-down.

The Burst Configuration Register bits M2-M0 specify the burst length (1, 2, 4, 8 or continuous); bit M3 specifies Asynchronous Random Read or Asynchronous Latch Enable Controlled Read; bits M4 and M5 are not used; bit M6 specifies the rising or falling burst clock edge as valid; bit M7 specifies the burst type (Sequential or Interleaved); M8 specifies the Valid Data Ready output period; bit M9 specifies the Y-latency; bit M10 is not used; M14-M11 specify the X-latency; and bit M15 selects between Synchronous Burst Read or Asynchronous Read. M10, M5 and M4 are reserved for future use.

M15 Read Select

The device features three kinds of read operation: Asynchronous Random Read, Asynchronous Latch Enable Controlled Read and Synchronous Burst Read. Page Read may be used in either of the Asynchronous Read operations.

The Burst Configuration Register bit M15 selects between Synchronous Burst and Asynchronous Read.

M14 - M11 and M9 X and Y Latency.

The values of X and Y are used to define the burst latency for the data sequence. The X-latency defines the number of clock cycles before the output of the first data from the clock edge that latches the address. The X-latency can be set from 7 to 16. A value of 7 is only valid for continuous burst.

The Y-latency is the number of clock cycles needed to output the next data from the burst register, following the first data output. The latency can be set to 1 or 2 clock cycles.

The minimum X-Latency value to consider depends on the Burst Clock K signal frequency. The burst performance in terms of frequency is listed in Table 11 and indicates the minimum X-latency and Y-latency values (X.Y.Y.Y) related to the burst type, burst length and x16 or x32 organisation.

M8 Valid Data Ready R Signal Configuration.

The Valid Data Ready R output signal indicates when valid data is on the data outputs synchronous with the valid burst clock edge. It can be asserted by the device synchronously with the valid clock edge or one clock cycle before.

M7 Burst Type.

Accesses within a given burst may be programmed to be either Sequential or Interleaved. This is referred to as the burst type and is selected by the Burst Configuration Register M7 bit. The access order within a burst is determined by the burst length, the burst type and the starting address (See Table 8).

M6 Valid Clock Edge Configuration.

All the synchronous operations such as Burst Read, Output Data or Ready signal validation can be synchronized on the valid rising or on the falling edge of the Burst Clock signal K.

M2 - M0 Burst Length.

Synchronous reads have a programmable burst length, set using the M2 - M0 bits of the Burst Configuration Register. The burst length corresponds to the maximum number of Words or Double-Words that can be output. Burst lengths of 1, 2, 4 or 8 are available for both the Sequential and Interleaved burst types, and a continuous burst is available for the Sequential type. The burst length of 8 is not available in the x32 configuration.

When a Read command is issued, a block of Words or Double-Words equal to the burst length is selected. All accesses for that burst take place

within this block, meaning that the burst wraps within the burst block if a boundary is reached.

If a Continuous Burst Read has been initiated the device will output data synchronously. Depending on the starting address of the read, the device activates the Valid Data Ready R output to indicate that it needs a delay to complete the internal read operation before outputting data. If the starting address is aligned to a four Word boundary the continuous burst mode will run without activating the Valid Data Ready R output. If the starting address is not aligned to a four Word boundary, Valid Data Ready R is activated at the beginning of the continuous burst read to indicate that the device needs an internal delay to read the content of the four successive words in the array.

Pipelined Burst Read.

An overlapping Burst Read operation is possible. That is, the address and data phases of consecutive synchronous read operations can be overlapped by several clock cycles. This is done by applying a pulse on Latch Enable \bar{L} input to latch a new address before the completion of the data output of the current cycle. This reduces or avoids wait-states in the data output for the burst read mode. The minimum clock edge number for the following read sequence must be six before the last data output of the previous read cycle. The pipelined burst read mode is available in the x16 organisation for both burst length definitions of four and eight, and in the x32 organisation for the burst length of four. It is not possible for a burst length of one or two.

Table 8. Burst Type Definition (x16 mode)

Burst Length	Starting Address (binary)	Sequential (decimal)	Interleaved (decimal)
	A3-A2-A1		
2	0-0-0	0-1	0-1
	0-0-1	1-0	1-0
4	0-0-0	0-1-2-3	0-1-2-3
	0-0-1	1-2-3-0	1-0-3-2
	0-1-0	2-3-0-1	2-3-0-1
	0-1-1	3-0-1-2	3-2-1-0
8	0-0-0	0-1-2-3-4-5-6-7	0-1-2-3-4-5-6-7
	0-0-1	1-2-3-4-5-6-7-0	1-0-3-2-5-4-7-6
	0-1-0	2-3-4-5-6-7-0-1	2-3-0-1-6-7-4-5
	0-1-1	3-4-5-6-7-0-1-2	3-2-1-0-7-6-5-4
	1-0-0	4-5-6-7-0-1-2-3	4-5-6-7-0-1-2-3
	1-0-1	5-6-7-0-1-2-3-4	5-4-7-6-1-0-3-2
	1-1-0	6-7-0-1-2-3-4-5	6-7-4-5-2-3-0-1
	1-1-1	7-0-1-2-3-4-5-6	7-6-5-4-3-2-1-0

Table 9. Burst Type Definition (x32 mode)

Burst Length	Starting Address (binary)	Sequential (decimal)	Interleaved (decimal)
	A2-A1		
2	0-0	0-1	0-1
	0-1	1-0	1-0
4	0-0	0-1-2-3	0-1-2-3
	0-1	1-2-3-0	1-0-3-2
	1-0	2-3-0-1	2-3-0-1
	1-1	3-0-1-2	3-2-1-0

Table 10. Burst Configuration Register (1)

BCR mode bit	Description	Value	Description
M15	Read Select	0	Synchronous Burst Read
		1	Asynchronous Read
M14-M11	X-Latency (4)	0001	Reserved
		0010	7, only for $F_K = 33\text{MHz}$ (5)
		0011	8, only for $F_K = 33\text{MHz}$
		0100	9, only for $F_K = 33\text{MHz}$
		0101	10, only for $F_K = 50\text{MHz}$ (6)
		0110	11, only for $F_K = 50\text{MHz}$ (7)
		1001	12, only for $F_K = 50\text{MHz}$
		1010	13, only for $F_K = 50\text{MHz}$
		1011	14, only for $F_K = 66\text{MHz}$ (8)
		1101	16, only for $F_K = 66\text{MHz}$
M9	Y-Latency (4)	0	One Burst Clock cycle
		1	Two Burst Clock cycles
M8	Valid Data Ready	0	R valid Low during valid Burst Clock edge
		1	R valid Low one data cycle before valid Burst Clock edge
M7	Burst Type	0	Interleaved
		1	Sequential
M6	Valid Clock Edge	0	Falling Burst Clock edge
		1	Rising Burst Clock edge
M3	Asynchronous	0	Random Read
		1	Latch Enable Controlled Read
M2-M0	Burst Length (2)	100	1 Word or Double-Word
		101	2 Words or Double-Words
		001	4 Words or Double-Words
		010	8 Words or Double-Words (3)
		111	Continuous

Note: 1. The BCR defines both the read mode and the burst configuration.

2. Synchronous burst length is defined as Word or Double-Word, the data bus width depends only on the $\overline{\text{WORD}}$ input.

Asynchronous Page read is two Words or one Double-Word.

3. A burst length of 8 is not available for x32 organisation.

4. At $F_K > 50\text{MHz}$ when X-Latency = 10 or 12, Y-Latency = 2 independent of the value of M9.

At $F_K = 66\text{MHz}$ when X-Latency = 14 or 16, Y-Latency = 2 independent of the value of M9.

5. Latency 7 valid only for continuous burst. Otherwisw Latency = 8.

6. Latency 10 valid only for continuous burst. Otherwisw Latency = 12.

7. Latency 11 valid only for continuous burst. Otherwisw Latency = 12.

8. Latency 14 valid only for continuous burst. Otherwisw Latency = 16.

Table 11. Burst Performance ⁽¹⁾

X-Y Latencies (minimum)						Clock Frequency
x16 organisation		x32 organisation		x16 organisation	x32 organisation	
Sequential	Interleaved	Sequential	Interleaved	V _{DD} = 2.7 to 3.6V		
Burst length: 1,2,4,8	Burst length: 1,2,4,8	Burst length: 1,2,4	Burst length: 1,2,4	Continuous Burst		
8.1.1.1	8.1.1.1	8.1.1.1	8.1.1.1	7.1.1.1	7.1.1.1	≤ 33 MHz
12.1.1.1	12.1.1.1	12.1.1.1	12.1.1.1	10.1.1.1	10.1.1.1	≤ 50 MHz
t.b.a.	t.b.a.	t.b.a.	t.b.a.	t.b.a.	t.b.a.	≤ 60 MHz
16.2.2.2	16.2.2.2	16.2.2.2	16.2.2.2	14.2.2.2	14.2.2.2	≤ 66 MHz

Note: 1. The burst length of 8 is not available in the x32 organisation.

INSTRUCTIONS AND COMMANDS

The Command Interface latches commands written to the memory. Instructions are made up of one or more commands to perform:

- Read Array (RD),
- Read Electronic Signature or Read Block Protection (RSIG),
- Read Status Register (RSR),
- Read Query (RCFI),
- Clear Status Register (CLRS),
- Block Erase (EE),
- Write to Buffer and Program (WBPR),
- Erase/Program Suspend (PES),
- Erase/Program Resume (PER),
- Set Burst Configuration Register (SBCR),
- Block Protect (BP), and
- Block Unprotect (BU).

Instructions (see Table 12) are composed of a first write sequence followed by either a second write sequence needed to confirm an Erase or Program instruction or by a read operation in order to read data from the array, the Electronic Signature, the Block Protection information, the CFI or the Status Register information. The instructions for Write to Buffer and Program and Block Erase operations consist of two commands written into the memory Command Interface (C.I.) that start the automatic P/E.C. operation. Erasure of a memory block may be suspended, in order to read data from or to program data in an other block, and then be resumed. Write to Buffer and Program operation may be suspended, in order to read data from another block, and then be resumed.

At power-up the Command Interface is reset to Read Array. The appropriate Instruction must be given to access Read Query (RCFI), Read Electronic Signature or Block Protection Status (RSIG) or Read Status Register (RSR). Reading of the memory array is disabled during a Block Protect/Unprotect (BP, BU), a Block Erase (EE) or a Write to Buffer and Program (WBPR) Instruction. A Erase/Program Suspend Instruction (PES) must be given to read under these conditions.

Read Array Instruction (RD). The Read Array Instruction consists of one write cycle giving the command FFh. Subsequent read operations will read the array content addressed and output the corresponding data. The Read Array Instruction remains active until another one is written into the Command Interface. At Power-up or at the exit of the Reset/Power-down mode, the device is by default initialised to Read Array.

Read Electronic Signature Instruction (RSIG).

An Electronic Signature can be read from the memory allowing programming equipment or applications to automatically match their interface to the characteristics of the device.

The Electronic Signature instruction consists of a first write cycle giving the command 90h, followed by a subsequent read which will output the Manufacturer Code, the Device Code or the Block Protection Status. The Manufacturer Code is output when all the address inputs are at V_{IL}. The Device Code is output when A1 (for the M58LW064A) or A2 (for the M58LW064B) is at V_{IH}, with all other address inputs at V_{IL}. The code is output on DQ0-DQ7 with DQ8-DQ31 at V_{IL}.

The RSIG Instruction also allows access to the Block Protection Status for the selected block address defined by A17-A22. After the Read Electronic Signature (RSIG) command, A1-A2 (for the M58LW064A) or A2-A3 (for the M58LW064B) are set to V_{IH}, while A17-A22 define the address of the block to be queried. A read operation outputs 01h if the block is protected and 00h if the block is not protected.

Read Query Instruction (RCFI). The Read Query Instruction is initiated with one write cycle giving the command 98h at any address. Subsequent read operations, depending on the address specified, will output the Block Status information, the Common Flash Interface ID string, the System Interface information, the Device Geometry Configuration or STMicroelectronics Specific Query information. The address mapping for the information is shown in Table 14.

Read Status Register Instruction (RSR). The Read Status Register Instruction consists of one write cycle giving the command 70h. Subsequent read operations, independent of the address, output the Status Register information that indicates if a Block Erase, Write to Buffer and Program, Block Protect or Block Unprotect operation has been completed successfully. See Table 12. Once initiated the RSR Instruction is active until another command is given to the Command Interface.

For Asynchronous Read, the Status Register information is present on the output data bus when both Chip Enable \bar{E} and Output Enable \bar{G} are Low. In Synchronous Burst Read the Status Register information is output on the data bus DQ1-DQ7 when Latch Enable \bar{L} goes High or on a valid Burst Clock K edge (M6 in the Burst Configuration Register specifies the rising or falling valid clock edge) when Latch Enable \bar{L} is low. An interactive update of the status register information is possible by toggling Output Enable \bar{G} , or when the device is

Table 12. Instructions

Mnemonic	Instruction	Cycles	1st Cycle			2nd Cycle			Comments
			Op.	Address	Data	Op.	Address	Data	
RD	Read Array	1+	Write	X	FFh				Read Array until a new write cycle is initiated
RSIG	Read Manufacturer Code	≥ 2	Write	X	90h	Read	000000h	20h	Read Manufacturer Code
RSIG	Read Device Code or Block Protection Status	≥ 2	Write	X	90h	Read	IAh	IDh	Read Device ID Code
RSR	Read Status Register	2	Write	X	70h	Read	X	SRDh	SRD = Status Register Data
RCFI	Read Query	≥ 2	Write	X	98h	Read	QAh	QDh	QA = Query Address QD = Query Data
CLRS	Clear Status Register	1	Write	X	50h				
EE	Block Erase	2	Write	X	20h	Write	BAh	D0h	BA = Block Address to erase
WBPR	Write to Buffer and Program	≥ 2	Write	BAh	E8h	Write	BAh	N	BA = Block Address N = Word/Double-Word Count Argument
PES	Erase/Program Suspend	1	Write	X	B0h				
PER	Erase/Program Resume	1	Write	X	D0h				Confirm command for Write to Buffer and Program instruction
SBCR	Set Burst Configuration Register	2	Write	BCR _h	60h	Write	BCR _h	03h	BCR = Burst Configuration Register
BP	Block Protect	2	Write	BAh	60h	Write	BAh	01h	Keep the Block Protect bit active of the selected block BA = Block Address
BU	Block Unprotect	2	Write	X	60h	Write	X	D0h	Clear all the Block protect bits simultaneously

dis-activated by Chip Enable \bar{E} High and then re-activated by Chip Enable \bar{E} and Output Enable \bar{G} Low, during an Erase or Program operation. The content of Status Register may also be read at the completion of an Erase/Program and/or Suspend

operation. During a Block Erase, Write to Buffer and Program, Block Protect or Block Unprotect Instruction, DQ7 indicates the P/E.C. status. It is valid until the operation is completed or suspended, DQ0-DQ7 output the Status Register content and DQ8-DQ31 are Low.

Table 13. Status Register Definition

Mnemonic	DQ	Function	Status
P/ECS	DQ7	P/E.C. Status	1 = Ready 0 = Busy ⁽¹⁾
ESS	DQ6	Erase Suspend Status	1 = Block Erase Suspended 0 = Block Erase in Progress/Completed ⁽²⁾
ES	DQ5	Erase/Block Unprotect Status ⁽⁷⁾	1 = Error in Block Erase operation or Block Unprotect 0 = Successful Block Erase operation or Block Unprotect ⁽³⁾
PS	DQ4	Write to Buffer and Program/Block Protect Status ⁽⁷⁾	1 = Error in Write to Buffer and Program, Block Protect ⁽⁴⁾ 0 = Write to Buffer and Program, Block Protect Completed successfully
	DQ3	Not used	
PSS	DQ2	Program Suspend Status	1 = Program Suspended 0 = Program operation in Progress/Completed ⁽⁵⁾
EPPB	DQ1	Erase/Write to Buffer and Program in a Protected Block	1 = Error in the defined operation 0 = Operation in Progress/Completed ⁽⁶⁾
	DQ0	Not used	

- Note: 1. DQ0-DQ6 are High Impedance when DQ7 is indicating that the part is busy. Status Register P/ECS bit7 indicates the P/E.C. status, check during Program or Erase, and on completion before checking bit4 or bit5 for Program or Erase Success.
2. DQ6 indicates the Erase Suspend Status. On an Erase Suspend instruction P/ECS and ESS bits are set to '1'. ESS bit remains '1' until an Erase Resume instruction is given.
3. Erase Status, ES bit5 is set to '1' if the P/E.C. has applied the maximum number of erase pulses to the block without achieving an erase verify.
4. Program Status, PS bit4 is set to '1' if the P/E.C. has failed to program a Word or Double-Word.
5. DQ2 indicates the Program Suspend Status. On a Program Suspend instruction P/ECS and PSS bits are set to '1'. PSS bit remains '1' until an Program Resume instruction is given.
6. DQ1 defines the status of an Erase or Write to Buffer and Program instruction defined in a protected block. \overline{RP} pin must be held at V_{HH} to temporarily override the block protect feature once it has been enabled.
7. DQ5 and DQ4 simultaneously at '1' after an Erase or Block Unprotect instruction indicates that an improper command was entered.

Clear Status Register Instruction (CLRS). The Clear Status Register Instruction is given with the command 50h at any address location. It is a reset instruction that resets DQ5, DQ4 and DQ1 in the Status Register to '0'.

If an operation such as Block Erase, Write to Buffer and Program Block Protect or Block Unprotect has failed, the P/E.C. will set DQ5, DQ4 or DQ1 to '1' depending on the failure detected (see Table 12, Status Register Definition). The Clear Status Register Instruction must be given before restarting any corrective Erase/Program Instruction. The CLRS Instruction should be given also after an Erase or Program Suspend Instruction failure or before a Resume Instruction if the previous instruction has been detected to have failed. It is also a software reset solution that may allow the execution of several operations such as cumulated Erase or Block Protect operations of multiple blocks. The Clear Status Register instruction is valid when the P/E.C. is inactive or the device is in a suspend mode and it is also valid independent of the voltage V_{IH} or V_{HH} applied on the \overline{RP} input.

Write to Buffer and Program Instruction (WBPR). The Write to Buffer and Program Instruction is used to program the memory array. Up to 16 Words or 8 Double-Words can be loaded into the Write Buffer and programmed into the device. The Write to buffer and Program Instruction is composed of three successive steps. The first step is to give the Write to Buffer and Program command, E8h with the selected memory Block Address where the program operation should occur. The Status Register DQ7 bit then indicates the "buffer available" status. If the write buffer is not available (indicated by DQ7 = 0) then the software can either continue monitoring DQ7 until it transitions to 1, or else re-try later by reloading first the WBPR command, E8h, and then again monitoring the value of DQ7.

Once the "write buffer available" condition is valid (indicated by DQ7 = 1), the second step is to write the block address again, along with the value N, where N+1 is the number of Words (x16 organisation) or Double-Words (x32 organisation) to be programmed.

In the third step, a sequence of N+1 write cycles loads the addresses and data to the write buffer (see boundary constraints below). The addresses

must lie between the starting address and the starting address + (N+1).

The array must be programmed in 4 Word or 2 Double-Word blocks, which must be aligned with an $A2 = A1 = 0$ starting address (or $A2 = 0$ for x32 organisation). Invalid data will be flagged and the operation will abort with the status register bits DQ4 and DQ5 set to 1.

The Confirm Command, D0h (the same as Erase/Program Resume PER Instruction) needs to be given immediately after the completion of the Write to Buffer and Program Instruction. It represents the last (that is the N+2) write operation.

The P/E.C. is enabled only if the whole previous sequence is fully respected. Otherwise an Invalid Command/Sequence error will be generated with the Status Register DQ5 and DQ4 set to '1'. For additional Write to Buffer and Program operations, after the initial input command the software can check the availability of the write buffer by checking DQ7 status from the Status Register.

If an error appears during a program sequence, the device will stop its operation and DQ4 of the Status Register will be set to '1' to indicate a program failure. DQ5 will indicate if an error has been detected during a Block Erase operation. If these bits, DQ4 or DQ5 are set to '1', the Write to Buffer and Program input command is not accepted by the device until the status register has been cleared.

Additionally, if the Block is protected and $V_{IH} < \overline{RP} < V_{HH}$ instead of $\overline{RP} = V_{HH}$, the Write to Buffer and Program Instruction will not be accepted by the device, and DQ4 and DQ1 of the status register will be set to '1'.

Block Protect Instruction (BP). The Block Protect Instruction BP uses a two-cycle write sequence. The first write cycle gives the command 60h at any address location. The second write cycle gives the block address memory location to be protected and the command 01h.

Block protection can be cleared with the BU Instruction, which unprotects all blocks. Alternatively, temporary unprotect can be achieved by raising the \overline{RP} input to V_{HH} and holding it at that level throughout the Block Erase or Write to Buffer and Program operations.

Block Unprotect Instruction (BU). The Block Unprotect Instruction BU uses a two-cycle write sequence. All the Block Protect bits are simultaneously erased. The Block Protect bit register is erased by giving the command 60h and then the Confirm command D0h, at any address location. The sequence is aborted if the Confirm command is not given and the device will output the Status Register Data with DQ4 and DQ5 set to '1'.

Block Erase Instruction (EE). The Block Erase Instruction EE uses a two-cycle command sequence. The Erase Setup command 20h is written to any address location. Then a second write cycle is given with the block address to be erased and the Confirm command D0h. The sequence is aborted if the Confirm command is not given and the device will output the Status Register Data with DQ4 and DQ5 set to '1'.

During the execution of the erase cycle by the P/E.C., the memory accepts only the Erase/Program Suspend instructions. Read operations output the Status Register bits. A complete state of the erase operation is given by the Status Register bits.

Erase/Program Suspend Instruction (PES).

The Block Erase or Write to Buffer and Program operations may be suspended by writing the command B0h at any address. The Erase/Program Suspend Instruction interrupts the P/E.C. Erase or Program sequence at a predetermined point in the algorithm. After the Suspend command is written the device outputs the Status Register data.

It is possible to read or program data in a block other than the one in which the Erase Suspend operation is effective. It is only possible to read in a block other than the one in which a Program Suspend operation is effective. The suspended Erase/Program operation has to be resumed in order to complete the previous erase/program sequence.

The Erase Suspend instruction is accepted only during a Block Erase operation execution. Program Suspend also is valid only during the Write to Buffer and Program instruction execution. Block Erase or Erase/Program Suspend instructions are

ignored if the memory is already in the Suspend mode.

The Suspend Instruction may be presented at any time during the execution of a Block Erase. For a Write to Buffer and Program instruction the Suspend Instruction is accepted only when the P/E.C. is running.

The device outputs information about the suspend in the Status Register information on DQ7, DQ6 and DQ2. If the operation has been completed DQ7 = '1' and DQ6 = '0' (Erase Suspend) or DQ2 = '0' (Program Suspend).

If the Suspend instruction occurred after the P/E.C. has completed its operation (DQ7 = 1, DQ6 = 0 and DQ2 = 0), the Status Register information remains available by toggling Output Enable \bar{G} . No command is accepted by the device with the exception of a Read Memory Array Instruction FFh. After the FFh Command is issued, the device is ready for Read Array (in the mode defined by the last Set Configuration Register issued).

When a program operation is completed inside a Block Erase Suspend Instruction, Read Array Instruction FFh will reset the device to Read Array. The Erase Resume Instruction has to be issued to complete the whole sequence.

When erase is suspended, the memory will respond only to the Read Array, Read Electronic Signature, Read Query, Read Status Register, Clear Status Register, Erase/Program Resume and the Write to Buffer and Program instructions.

When a Write to Buffer and Program instruction is suspended, the memory will respond only to the Read Array, Read Electronic Signature, Read Query, Read Status Register, Clear Status Register and Erase/Program Resume instructions.

Erase/Program Resume Instruction (PER). If an Erase Suspend instruction was previously executed, the erase operation may be resumed by giving the command D0h, at any address. This also serves as the Confirm command for the Write to Buffer and Program (WPBR) Instruction which is issued after the write buffer loading sequence is completed, and which starts the P/E.C.

Set Burst Configuration Register (SBCR).

This instruction uses two command cycles. The Burst Configuration Setup command 60h is written with the address corresponding to the Set Burst Configuration Register content. Then in the second write cycle the address bus A2-A17 specifies the BCR, Burst Configuration Register, information and the command 03h. The burst length, type, latency, synchronous/asynchronous read mode and clock edge active configuration are defined in that operation. After the command 03h the device will default in the Read array mode.

Status Register Bits. The P/E.C. status is indicated during execution with a Ready/Busy output available on DQ7. Any read attempt during Program or Erase command execution will automatically update the Status Register bits. The P/E.C. automatically sets bits DQ1, DQ2, DQ4, DQ5, DQ6 and DQ7. The bit DQ0 is reserved for future use and should be masked. It is not necessary to specify an address when the Status Register bits are read. The Status Register is a static memory register that is reset when RP signal is active or on a power-down operation.

POWER SUPPLY

Power Down. The memory provides Reset/Power-down control using the input \overline{RP} . When Reset/Power-down \overline{RP} is pulled to V_{IL} the supply current drops to typically less than $1\mu A$, the memory is deselected and the outputs are at high impedance. If \overline{RP} is pulled to V_{IL} during a Program or Erase operation, this operation is aborted after a latency time of t_{PLRH} and the memory content is no longer valid.

RESET, POWER-DOWN AND POWER-UP

See Fig 16.

The device is reset if the Reset/Power-down \overline{RP} input is pulled to V_{IL} for longer than t_{PLPH} . If the device was in a Read mode then it will recover

from reset after a time of t_{PHQV} to give valid data output. If the device was executing an Erase or Program operation, with the P/E.C. active, the operation will abort in a time of t_{PLRH} maximum. The device will be ready to accept new write commands after a time of t_{PHWL} or t_{PHEL} .

The supply voltages V_{DD} and V_{DDQ} must be high a time t_{VDHEL} or t_{VDHWL} before a read or write cycle. At first power up Reset/Power-down should be held Low for a time of t_{VDHPH} after V_{DD} and V_{DDQ} are high. The device will be ready to accept its first read or write commands after a time of t_{PUR} or t_{PUW} .

COMMON FLASH INTERFACE - CFI

The introduction to the JEDEC CFI specification Rel. 1.2 quotes, "The Common Flash Interface (CFI) specification outlines a device and host system software interrogation handshake which allows specific software algorithms to be used for entire families of devices. This allows device-independent, JEDEC, ID independent and forward- and backward-compatible software support for the specified flash device families. It allows flash vendors to standardize their existing interfaces for long-term compatibility."

The CFI Query instruction RCFI describes how the device enters the CFI Query mode which enables information to be read from the Flash memory. CFI allows a system software to query the flash device to determine various electrical and timing parameters, density information and functions supported by the device. CFI allows the system to easily interface to the flash memory, to learn about its features and parameters, enabling the software to upgrade itself when necessary.

Query Structure Overview

The flash memory displays the CFI data structure when the CFI Query Instruction RCFI is issued. A list of the main subsections is detailed in Tables 15 to 19.

M58LW064A, M58LW064B

Table 14. Query Structure Overview

Offset	Sub-section Name	Description
00h		Manufacturer Code
01h		Device Code
10h	CFI Query Identification String	Command set ID and algorithm data offset
1Bh	System Interface Information	Device timing and voltage information
27h	Device Geometry Definition	Flash device layout
P(h)	Primary Algorithm-specific Extended Query table	Additional information specific to the Primary Algorithm (optional)
A(h)	Alternate Algorithm-specific Extended Query table	Additional information specific to the Alternate Algorithm (optional)
(BA+3)h	Block Status Register	Block-related Information

Table 15. CFI - Query Address and Data Output in the x16/x32 organization

Address ⁽⁴⁾ A22-A1 (M58LW064A) A22-A2 (M58LW064B)	Data		Instruction
10h	51h	"Q"	Query ASCII String 51h; "Q" 52h; "R" 59h; "Y"
11h	52h	"R"	
12h	59h	"Y"	
13h	20h		Primary Vendor: Command Set and Control Interface ID Code
14h	00h		
15h	31h		Primary algorithm extended Query Address Table: P(h)
16h	00h		
17h	00h		Alternate Vendor: Command Set and Control Interface ID Code
18h	00h		
19h	31h		Alternate Algorithm Extended Query address Table
1Ah	00h		

- Note: 1. The x8 or Byte Address mode is not available.
 2. In the x16 organization, the value of the address location of the CFI Query is independent of A1 pad (M58LW064B).
 3. Query Data are always presented on the lowest order data outputs (DQ7-DQ0) only. Others data (DQ31-DQ8) are set to '0'.
 4. For M58LW064B, A1 = Don't Care.

Table 16. CFI - Device Voltage and Timing Specification

Address ⁽⁴⁾ A22-A1 (M58LW064A) A22-A2 (M58LW064B)	Data	Instruction
1Bh	27h ⁽¹⁾	V _{CC} Min, 2.7V
1Ch	36h ⁽¹⁾	V _{CC} max, 3.6V
1Dh	00h ⁽²⁾	V _{PP} min – Not Available
1Eh	00h ⁽²⁾	V _{PP} max – Not Available
1Fh	00h ⁽³⁾	2 ^N ms Word, DWord prog. typical time-out
20h	x07h	2 ^N ms, typical time out for max buffer write
21h	0Ah	2 ^N ms, Erase Block typical time-out
22h	00h ⁽³⁾	2 ^N ms, chip erase time-out typ. – Not Available
23h	00h ⁽³⁾	2 ^N times typ. for Word Dword time-out max – Not Available
24h	04h	2 ^N times typ. for buffer write time-out max
25h	04h	2 ^N x typ. individual block erase time-out maximum
26h	00h ⁽³⁾	2 ^N times typ. for chip erase max time-out – Not Available

Note: 1. Bits are coded in Binary Code Decimal, bit7 to bit4 are scaled in Volt and bit3 to bit0 in mV.

2. Bit7 to bit4 are coded in Hexadecimal and scaled in Volt while bit3 to bit0 are in Binary Code Decimal and scaled in 100mV.

3. Not supported.

4. For M58LW064B, A1 = Don't Care.

Table 17. Device Geometry Definition

Address ⁽¹⁾ A22-A1 (M58LW064A) A22-A2 (M58LW064B)	Data	Instruction
27h	17h	2 ^N nb. of bytes device Size
28h	01h.	Device Interface Sync./Async.
29h	00h	Organisation Sync./Async.
2Ah	05h	Page size in bytes, 2 ^N
2Bh	00h	
2Ch	01h	Bit7-0 = nb of Erase Block region
2Dh	3Fh	Number (N-1) of Erase Blocks of identical size; N=64
2Eh	00h	
2Fh	00h	x times 256 bytes per Erase block (128K bytes)
30h	02h	

Note: 1. For M58LW064B, A1 = Don't Care.

M58LW064A, M58LW064B

Table 18. Block Status Register (see also, Table 6 and 7 in the datasheet)

Address A22-A2	Data (Hex) x32 organization		Selected Block Information
(BA+3)h ⁽¹⁾	bit0	0	Block Unlocked
		1	Block Locked
	bit1	0	Last erase operation ended successfully ⁽²⁾
		1	Last erase operation not ended successfully ⁽²⁾
	bit7-2	0	Reserved for future features

Note: 1. BA specifies the block address location, i-e, A22-A17.

2. Not Supported.

Table 19. Extended Query information

Address offset	M58LW064B - x32 M58LW064A - x16		M58LW064B - x16 organization		Instruction
	Address A22-A2	Data (Hex) x32 organization	Address A22-A1	Data	
(P)h	31h	50h "P"	62h, 63h	50h	Query ASCII string - Extended Table
(P+1)h	32h	52h "R"	64h, 65h	52h

(P+8)h	39h	00h	72h, 73h	00h	
(P+9)h	3Ah	01h	74h, 75h	00h	Function allowed after Suspend: Program allowed after Erase Suspend (1=yes) Bit 7-1 reserved for future use
(P+A)h	3Bh	00h ⁽²⁾	76h, 77h	00h ⁽²⁾	Block Status Register Mask
(P+C)h	3Ch	33h	78h, 79h	33h	V _{CC} OPTIMUM Program/Erase voltage conditions
(P+D)h	3Dh	50h	7Ah, 7Bh	50h	V _{PP} OPTIMUM Program/Erase voltage conditions
(P+E)h	3Eh	00h	7Ch, 7Dh	00h	Reserved for future use
(P+F)h	3Fh	00h	7Dh, 7Fh	00h	Reserved for future use

Note: 1. Bit7 to bit4 are coded in Hexadecimal and scaled in Volt while bit3 to bit0 are in Binary Code Decimal and scaled in mV.

2. Not supported.

Table 20. AC Measurement Conditions

Clock Rise and Fall Times	≤3ns
Input Rise and Fall Times	≤4ns
Input Pulses Voltages	0V to V _{DDQ}
Input and Output Timing Ref. Voltages	V _{DDQ} /2

Figure 7. AC Testing Input Output Waveform

Note: V_{DD} = V_{DDQ}.

Figure 8. AC Testing Load Circuit

Table 21. Capacitance (T_A = 25°C, f = 1 MHz)

Symbol	Parameter	Test Condition	Typ	Max	Unit
C _{IN}	Input Capacitance	V _{IN} = 0V	6	8	pF
C _{OUT}	Output Capacitance	V _{OUT} = 0V	8	12	pF

M58LW064A, M58LW064B
Table 22. DC Characteristics

 (T_A = 0 to 70°C, -40 to 85°C, V_{DD} = 2.7V to 3.6V)

Symbol	Parameter	Test Condition	Min	Max	Unit
I _{LI}	Input Leakage Current	0V ≤ V _{IN} ≤ V _{DDQ}		±1	μA
I _{LO}	Output Leakage Current	0V ≤ V _{OUT} ≤ V _{DDQ}		±5	μA
I _{CC}	Supply Current (Random Read)	$\bar{E} = V_{IL}, \bar{G} = V_{IH}, f_{add} = 6\text{MHz}$		30	mA
I _{CCB}	Supply Current (Burst Read)	$\bar{E} = V_{IL}, \bar{G} = V_{IH}, f_{clock} = 50\text{MHz}$		50	mA
I _{CC1}	Supply Current (Standby)	$\bar{E} = V_{DD} \pm 0.2\text{V},$ $\bar{RP} = V_{DD} \pm 0.2\text{V}$		40	mA
	Supply Current (Auto Low-Power)			2	mA
I _{CC2}	Supply Current (Reset/Power-down)	$\bar{RP} = V_{SS} \pm 0.2\text{V}$		1	μA
I _{CC3} (1)	Supply Current (Program or Erase, Set Lock Bit, Erase Lock Bit)	Write to Buffer and program Block Erase in progress		30	mA
I _{CC4}	Supply Current (Erase/Program Suspend)	$\bar{E} = V_{IH}$		40	μA
V _{IL}	Input Low Voltage		-0.5	0.4	V
V _{IH}	Input High Voltage		V _{DDQ} - 0.4	V _{DDQ} + 0.3	V
V _{OL}	Output Low Voltage	I _{OL} = 100μA		0.1	V
V _{OH}	Output High Voltage CMOS	I _{OH} = -100μA	V _{DDQ} - 0.1		V
V _{HH} (2)	\bar{RP} Hardware Block Unlock Voltage	Block Erase in progress, Write to Buffer and Program	8.5	9.5	V
V _{LKO}	V _{DD} Supply Voltage (Erase and Program lockout)			2.2	V

Note: 1. Sampled only, not 100% tested.

 2. Biasing \bar{RP} pin to V_{HH} is allowed for a maximum cumulative period of 80 hours.

 3. Current increases to I_{CC} + I_{CC5} during a read operation.

Table 23. Asynchronous Random Read(T_A = 0 to 70°C, -40 to 85°C, V_{DD} = 2.7V to 3.6V, V_{DDQ} = 1.8V to V_{DD})

Symbol	Parameter	Test Condition	Min	Max	Unit
t _{AVAV}	Address Valid to Address Valid	$\bar{E} = V_{IL}, \bar{G} = V_{IL}$	150		ns
t _{AVQV}	Address Valid to Output Valid	$\bar{E} = V_{IL}, \bar{G} = V_{IL}$		150	ns
t _{AXQX}	Address Transition to Output Transition	$\bar{E} = V_{IL}, \bar{G} = V_{IL}$	0		ns
t _{EHLX}	Chip Enable High to Latch Enable Transition		0		ns
t _{EHQX}	Chip Enable High to Output Transition	$\bar{G} = V_{IL}$	0		ns
t _{EHQZ}	Chip Enable High to Output Hi-Z	$\bar{G} = V_{IL}$		10	ns
t _{ELQV} ⁽¹⁾	Chip Enable Low to Output Valid	$\bar{G} = V_{IL}$		150	ns
t _{ELQX}	Chip Enable Low to Output Transition	$\bar{G} = V_{IL}$	0		ns
t _{GHQX}	Output Enable High to Output Transition	$\bar{E} = V_{IL}$	0		ns
t _{GHQZ}	Output Enable High to Output Hi-Z	$\bar{E} = V_{IL}$		10	ns
t _{GLQV}	Output Enable Low to Output Valid	$\bar{E} = V_{IL}$		50	ns
t _{GLQX}	Output Enable to Output Transition	$\bar{E} = V_{IL}$	0		ns
t _{LLEL}	Latch Enable Low to Chip Enable Low		10		ns

Note: 1. Output Enable \bar{G} may be delayed up to t_{ELQV} - t_{GLQV} after the falling edge of Chip Enable \bar{E} without increasing t_{ELQV}.**Figure 9. Asynchronous Random Read AC Waveforms**
