TYPE	TYPICAL CLOCK FREQUENCY	TYPICAL MAXIMUM POWER DISSIPATION
'165	26 MHz	210 mW
'LS165A	35 MHz	90 mW

**description**

The '165 and 'LS165A are 8-bit serial shift registers that shift the data in the direction of  $Q_A$  toward  $Q_H$  when clocked. Parallel-in access to each stage is made available by eight individual direct data inputs that are enabled by a low level at the shift/load input. These registers also feature gated clock inputs and complementary outputs from the eighth bit. All inputs are diode-clamped to minimize transmission-line effects, thereby simplifying system design.

Clocking is accomplished through a 2-input positive-NOR gate, permitting one input to be used as a clock-inhibit function. Holding either of the clock inputs high inhibits clocking and holding either clock input low with the shift/load input high enables the other clock input. The clock-inhibit input should be changed to the high level only while the clock input is high. Parallel loading is inhibited as long as the shift/load input is high. Data at the parallel inputs are loaded directly into the register while the shift/load input is low independently of the levels of the clock, clock inhibit, or serial inputs.
