## FEATURES

Operation from 400 MHz to 4000 MHz<br>Noise figure of 0.8 dB at 900 MHz<br>Requires few external components<br>Integrated active bias control circuit<br>Integrated dc blocking capacitors<br>Adjustable bias for low power applications<br>Single-supply operation from 3 V to 5 V<br>Gain of $\mathbf{2 1 . 5 ~ d B}$ at $900 \mathbf{~ M H z}$<br>OIP3 of $\mathbf{3 4 . 0} \mathbf{~ d B m}$ at $900 \mathbf{~ M H z}$<br>P1dB of $\mathbf{2 1 . 0 ~ d B m ~ a t ~} 900 \mathbf{~ M H z}$<br>Small footprint LFCSP<br>Pin-compatible version with $\mathbf{2 0 . 8} \mathbf{~ d B}$ gain available

## GENERAL DESCRIPTION

The ADL5523 is a high performance GaAs pHEMT low noise amplifier. It provides high gain and low noise figure for singledownconversion IF sampling receiver architectures as well as direct-downconversion receivers.

The ADL5523 provides a high level of integration by incorporating the active bias and the dc blocking capacitors, making it very easy to use while not sacrificing design flexibility.

## FUNCTIONAL BLOCK DIAGRAM

Figure 1.

The ADL5523 is easy to tune, requiring only a few external components. The device can support operation from 3 V to 5 V , and the current draw can be adjusted with the external bias resistor for applications requiring very low power consumption.

The ADL5523 comes in a compact, thermally enhanced, $3 \mathrm{~mm} \times$ 3 mm LFCSP and operates over the temperature range of $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$.

A fully populated evaluation board is also available.

## ABSOLUTE MAXIMUM RATINGS

Table 4.

| Parameter | Rating |
| :--- | :--- |
| Supply Voltage, VPOS | 5.5 V |
| RF Input Level | 7 dBm |
| RF Input Level (with $8 \Omega$ Series Resistor on VPOS) | 20 dBm |
| Internal Power Dissipation | 500 mW |
| $\theta_{\mathrm{JA}}$ (Junction to Air) | $50^{\circ} \mathrm{C} / \mathrm{W}$ |
| Maximum Junction Temperature | $150^{\circ} \mathrm{C}$ |
| Operating Temperature Range | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |

## ADL5523

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 2. Pin Configuration

Table 5. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :--- | :--- | :--- |
| 1 | VBIAS | Internal DC Bias. This pin should be connected to VPOS through the R1 resistor. |
| 2 | RFIN | RF Input. This is the input to the LNA. |
| $3,4,5,6$ | NC | No Connection. No internal connection. |
| 7 | RFOUT | RF Output. |
| 8 | VPOS | Supply Voltage. DC bias needs to be bypassed to ground using a low inductance capacitor. This pin is <br> also used for output matching. See the Basic Connections section. |
| 9 (EPAD) | Exposed Pad (EPAD) | GND. Connect the exposed pad to a low impedance ground plane. |

## BASIC CONNECTIONS

The basic connections for operating the ADL5523 are shown in Figure 52. Capacitor C5 provides the power supply decoupling. Inductor L1 (Coilcraft 0403HQ or 0402HP series) and Capacitor C1 (Murata High-Q GJM series or equivalent) provide the input impedance matching, and the output impedance matching is provided by either L2 or C3. Resistor R1 is used to set the supply current, and the value of R1 is indirectly proportional to the supply current (that is, increasing the value of R1 reduces the supply current). The recommended external components for selected frequencies are listed in Table 7.
For 5 V applications where the input power exceeds the input compression point of approximately 7 dBm , a series resistor (R2) of at least $8 \Omega$, with a high power rating ( 0.2 W minimum), should be inserted on the VPOS line to protect the device from the input power overdrive. In this case, reduce Resistor R1 from $1.3 \mathrm{k} \Omega$ to $600 \Omega$ to keep the supply current at around 60 mA . With R2 $=8.2 \Omega$ (Susumu RP1608S-8R2-F) and R1 $=600 \Omega$, the gain and noise figure for the ADL5523 are mostly unchanged. Table 6 lists OIP3 and P1dB at selected frequencies. For 3 V power supply applications, a series resistor is not necessary for the expected input overdrive powers up to 20 dBm .

## EVALUATION BOARD

Figure 53 shows the schematic of the ADL5523 evaluation board. The board is powered by a single supply, and dc bias can be applied to the board through clip-on leads at VPOS and GND or through a 2-pin connector, W1.
The evaluation board comes optimized at 1950 MHz from the factory, but it can be easily modified to work at any frequency between 400 MHz and 4 GHz . Table 7 lists the recommended components at various frequencies.

## SOLDERING INFORMATION AND RECOMMENDED PCB LAND PATTERN

Figure 56 shows the recommended land pattern for ADL5523. To minimize thermal impedance, the exposed pad on the package underside is soldered down to a ground plane. If multiple ground layers exist, they are stitched together using vias (a minimum of five vias is recommended). Pin 3 to Pin 6 can be left unconnected or can be connected to ground. For more information on land pattern design and layout, refer to the AN-772 Application Note, A Design and Manufacturing Guide for the Lead Frame Chip Scale Package (LFCSP).

[^1]
## TUNING THE ADL5523 FOR OPTIMAL NOISE FIGURE

The ADL5523 is a monolithic low noise amplifier (LNA) in a $3 \mathrm{~mm} \times 3 \mathrm{~mm}$ LFCSP. The evaluation board, as shipped from the factory, gives a noise figure of 0.9 dB over a bandwidth of several hundred megahertz. The specific frequency where optimal noise is reached depends on the tuning.
The bandwidth of the ADL5523 is 400 MHz to 4 GHz , although noise figure degrades above 2.5 GHz as the gain begins to roll off.

This section is based on Analog Devices, Inc., lab measurements. Although there are plots in which the Agilent Advanced Design System (ADS) environment is used, the data in these plots come entirely from Analog Devices lab measurements.

## TUNING S22

Tuning of the LNA begins with S22 (output tuning). Tuning of the LNA output is done by placing reactive components on the bias line, referred to in the schematic in Figure 53 as VPOS.
On the LNA evaluation board, S22 tuning is achieved by either the use of an inductor (L2) on the bias line or a shunt capacitor (C3) on the bias line to ground. Typically, either L2 is required or C3 but not both.

The evaluation board uses a slider on the bias line to make tuning for S22 as easy as possible. The slider is an area of ground etch adjacent to the bias line that is clear of solder mask. The bias line in this area is also free of solder mask. This allows a capacitor (C3) to be placed anywhere on the bias line to ground, which provides easy and accurate tuning for S22.
Note that the PCB layout shows two capacitors, C3 and C4. Typically, only one of these capacitors is needed for good S22 tuning.

The slider is seen in the LNA PCB layout in Figure 57 as the area near the red arrows to the right of the bias line. With a $0 \Omega$ resistor in place of L 2 , moving a 1 nF capacitor from the top to the bottom effectively tunes S22 from 1400 MHz to 3500 MHz . Table 8 shows the component values and placement required for S22 tuning from 800 MHz to 3200 MHz . For lower frequencies, higher values of L 2 can be used to tune S 22 , and for frequencies from 3.2 GHz to 4.0 GHz , smaller values of capacitors can be used on the slider.

Table 8. Capacitor and Inductor Tuning and Placement for LNA S22 Tuning

| Frequency (MHz) | L2 (nH) | C3 (nF) | C3 Placement |
| :--- | :--- | :--- | :--- |
| 800 | 3.4 | Open | $\mathrm{N} / \mathrm{A}$ |
| 1400 | $0 \Omega$ | 1 nF | 6 |
| 2000 | $0 \Omega$ | 1 nF | 4 |
| 2400 | $0 \Omega$ | 1 nF | 3 |
| 2800 | $0 \Omega$ | 1 nF | 2 |
| 3200 | $0 \Omega$ | 1 nF | 1 |

Figure 57. PCB Layout for LNA Evaluation Board (Note Slider on Bias Line with Capacitor Placement for S22 Tuning Noted by Arrows)

## TUNING THE LNA INPUT FOR OPTIMAL GAIN

LNAs are generally tuned for either gain or noise optimization, or some trade-off between the two. One figure of merit of an LNA is how much trade-off must be made for one of these parameters to optimize the other. With the ADL5523, an S11 of 6 dB to 8 dB at the input to the matching network can still be achieved typically when optimizing for noise.
For optimal gain matching, the goal is to use a matching network that converts the input impedance of the LNA to the characteristic impedance of the system, typically $50 \Omega$. Correct tuning for gain matching results in a conjugate match. That is, the impedance of the matching network at the LNA input, looking back toward the generator, is always the complex conjugate of the LNA input impedance when matched for gain.
Once $\mathrm{S} 11^{*}$, the complex conjugate of S 11 , is known, a matching circuit must be found that transforms the $50 \Omega$ system impedance into the conjugate S11 impedance. To do this, the designer starts at the origin of the Smith Chart circle and finds components that move the $50 \Omega$ match to $\mathrm{S} 11^{*}$.
The related impedances for gain matching are shown in Figure 58. A Smith Chart representation of the conjugate match is shown in Figure 59.

Figure 58. Matching LNA Input for Gain

Figure 59. Smith Chart Representation of Conjugate Match

## TUNING THE LNA INPUT FOR OPTIMAL NOISE FIGURE

The point in the Smith Chart at which matching for optimal noise occurs is typically referred to as gamma optimal or Горт. Typically, it is significantly different from the gain matching point; finding Гopt is not as obvious as the gain match. Гopt is a function of the semiconductor structure and characteristics of the LNA. The fabrication facility that produces the LNA typically has this information. Г opt $_{\text {can }}$ also be determined by doing source pull testing in the lab.
Noise matching for the ADL5523 is actually very easy because the area of the Smith Chart where the noise figure is optimal or near optimal is not confined to a narrow area around Горт. This is very advantageous because it means that component variations play a smaller part in the board-to-board variation of noise figure.
The matching area for optimal noise for the ADL5523 is shown in Figure 60. Note that textbooks usually define noise circles as a conjugate match. However, for the purpose of this data sheet, the circle is a direct match. To find the correct matching circuit, the designer must start with the S11 of the LNA and select components that move the S 11 to within this circle.
An important aspect of the overall ADL5523 ease of tuning is that as long as S22 is matched for a particular frequency, the noise matching area remains very consistent in its placement for that frequency. If S22 is matched, take the measured S11 and move it into the red circle shown in Figure 60 for optimal noise matching.

Figure 60. Area of Optimal Noise Matching for ADL5523

## ADL5523

## S11 OF THE LNA WITH S22 MATCHED

To determine the correct matching circuit for optimal noise, look at the results of S11 for the various frequencies at which S22 was tuned earlier in the Tuning S22 section. Once S11 is determined for a particular frequency, find the matching components that provided that match. Figure 62 and Figure 63 show S11 for the various frequencies. Again, these measurements are all based on S 22 being matched at that particular frequency. Note that, for the examples shown in Figure 62 and Figure 63, S11 is either in the lower left quadrant of the Smith Chart or slightly into the upper left. To move the impedance in the given noise circle, a series L component at the LNA input is required. The L values in the examples differ but a correct L value moves the match along the constant R circle up into the upper left quadrant of the Smith Chart.

A shunt capacitor can then be added to move the match along a constant admittance line, down and to the right, directly into the center of the noise circle given in Figure 60.

The solution for the structure of the match for the examples in Figure 62 and Figure 63 is a series L to the input of the LNA and a shunt capacitor at the generator end of this inductor. The recommended components for matching at various frequencies are shown in Table 7.

An example of the effect of the series $L$, shunt $C$ match, based on the 800 MHz example, is given in Figure 61. This example uses the output from the Agilent ADS Smith Chart tool.

Figure 61. Example of Series L, Shunt C Matching Network for $\Gamma$ opt
