

8-bit 160MSPS Flash A/D Converter

Description

The CXA3286R is an 8-bit high-speed flash A/D converter capable of digitizing analog signals at the maximum rate of 160MSPS. ECL, PECL or TTL can be selected as the digital input level in accordance with the application. The TTL digital output level allows 1:2 demultiplexed output.

Features

- Differential linearity error: $\pm 0.5\text{LSB}$ or less
- Integral linearity error: $\pm 0.5\text{LSB}$ or less
- Maximum conversion rate of 160MSPS
- Low input capacitance: 10pF
- Power saving function
- Wide analog input bandwidth: 250MHz
- Low power consumption: 550mW
- 1:2 demultiplexed output
- 1/2 frequency-divided clock output (with reset function)
- Compatible with ECL, PECL and TTL digital input levels
- TTL output "H" levels: 2.8V (Typ.)
- Output voltage control function (VOCLP)
- +3.3V line CMOS IC direct connecting available
- Single +5V power supply operation available
- Ultra-small surface mounting package (48-pin LQFP)

Structure

Bipolar silicon monolithic IC

Applications

- LCD monitors
- LCD projectors

Aperture Jitter Measurement Circuit

Integral Linearity Error Measurement Circuit

Differential Linearity Error Measurement Circuit

Aperture Jitter Measurement Method

Where σ (LSB) is the deviation of the output codes when the largest slew rate point is sampled at the clock which has exactly the same frequency as the analog input signal, the aperture jitter T_{aj} is:

$$T_{aj} = \sigma / \frac{\Delta v}{\Delta t} = \sigma / \left(\frac{256}{2} \times 2\pi f \right)$$

Error Rate Measurement Circuit

Description of Operation Modes

The CXA3286R has two types of operation modes which are selected with Pin 45 (SELECT1).

Operation mode	SELECT1 pin	Maximum conversion rate	Data output	Clock output
DMUX mode	Vcc	160MSPS	Demultiplexed output 80Mbps	The input clock is 1/2 frequency divided and output. 80MHz
Straight mode	GND	125MSPS	Straight output 125Mbps	The input clock is inverted and output. 125MHz

Table 2. Operation Mode Table

1. DMUX mode (See Application Circuit 1-(1), (2) and (3).)

Set the SELECT1 pin to Vcc for this mode. In this mode, the clock frequency is divided by 2 in the IC, and the data is output after being demultiplexed by this 1/2 frequency-divided clock. The 1/2 frequency-divided clock, which has adequate setup time and hold time for the output data, is output from the clock output pin.

When using the multiple CXA3286R in DMUX mode, the start timing of the 1/2 frequency-divided clocks becomes out of phase, producing operation such as that shown in the example on the next page. As a countermeasure, the CXA3286R has a function that resets the 1/2 frequency-divided clocks.

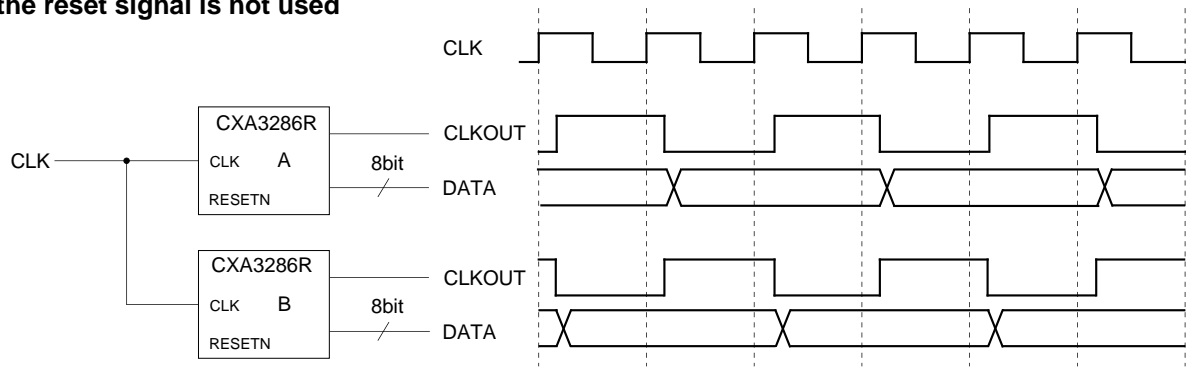

When resetting this 1/2 frequency-divided clock, the low level of the reset signal should be input to the RESETN pin (Pin 46 or 48). The reset signal requires the setup time ($T_{rs} \geq 1.0\text{ns}$) and hold time ($T_{rh} \geq -0.5\text{ns}$) to the clock rising edge because it is synchronized with and taken in the clock.

The reset period can be extended by making the low level period of the reset signal longer because the clock output pin is fixed to low (reset) during the low level period at the clock rising edge. If the reset start timing is regarded as not important, the timing where the reset signal is set from high to low is not so consequence. However, when the reset is released the timing where the reset signal is set from low to high must become significant because the timing is used to commence the 1/2 frequency-divided clock. In this case, the setup time (T_{rs}) is also necessary.

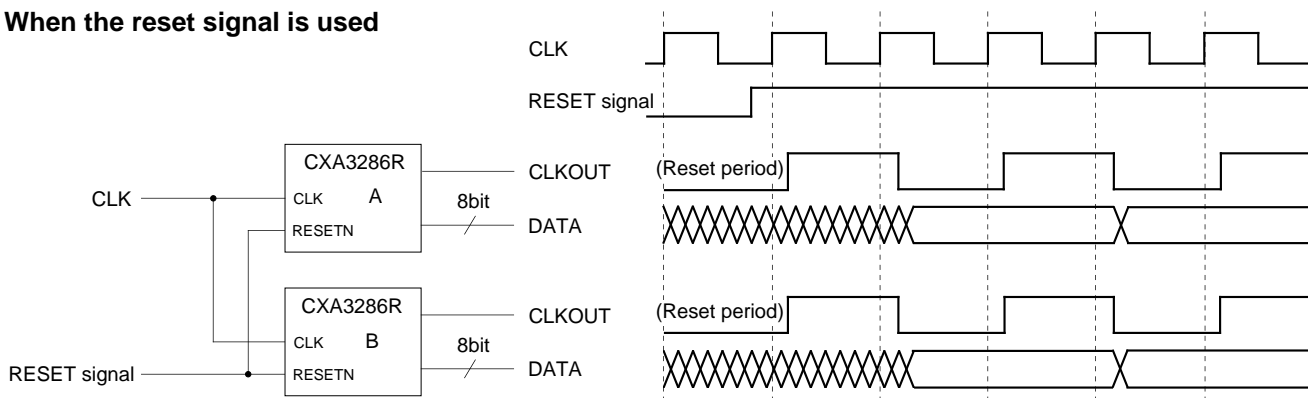

See the timing chart for detail. (This chart shows the example of reset for 2T.)

The A/D converter can operate at $F_c (\text{min.}) = 160\text{MSPS}$ in this mode.

When the reset signal is not used

When the reset signal is used

2. Straight mode (See Application Circuits 1-(4), (5) and (6).)

Set the SELECT1 pin to GND for this mode. In this mode, data output can be obtained in accordance with the clock frequency applied to the A/D converter for applications which use the clock applied to the A/D converter as the system clock.

The A/D converter can operate at F_c (min.) = 125MSPS in this mode.

Digital input level and supply voltage settings

The logic input level for the CXA3286R supports ECL, PECL and TTL levels.

The power supplies (DV_{EE3}, DGND3) for the logic input block must be set to match the logic input (CLK and reset signals) level.

Digital input level	DV _{EE3}	DGND3	Supply voltage	Application circuits
ECL	-5V	0V	±5V	(1) (4)
PECL	0V	+5V	+5V	(2) (5)
TTL	0V	+5V	+5V	(3) (6)

Table 3. Logic Input Level and Power Supply Settings

Description of SELECT2 pin

The CXA3286R has two systems of data outputs and the port where the data is output can be selected by the SELECT2 pin.

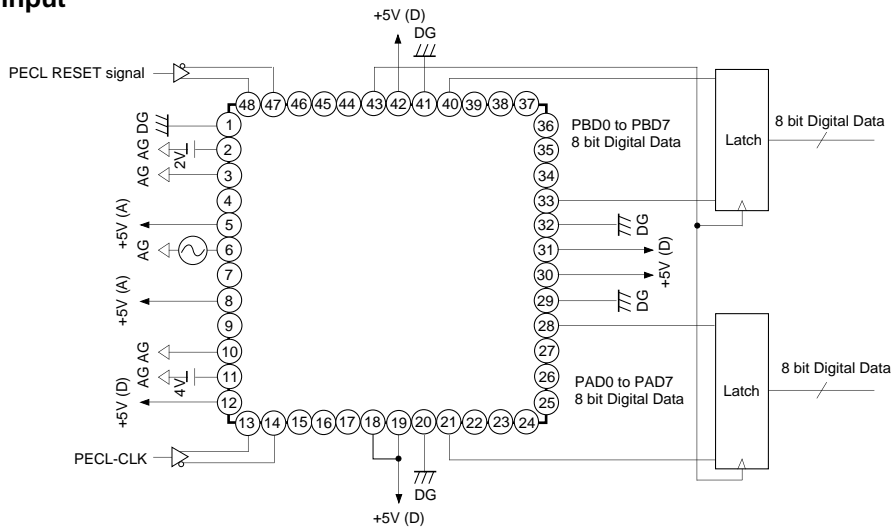

SELECT2 pin	Data output
Open	PA and PB both sides output possible
V _{cc1}	PA side output possible; PB side in high impedance
GND1	PB side output possible; PA side in high impedance

Application Circuit 1

(1) DMUX ECL input

(2) DMUX PECL input

(3) DMUX TTL input

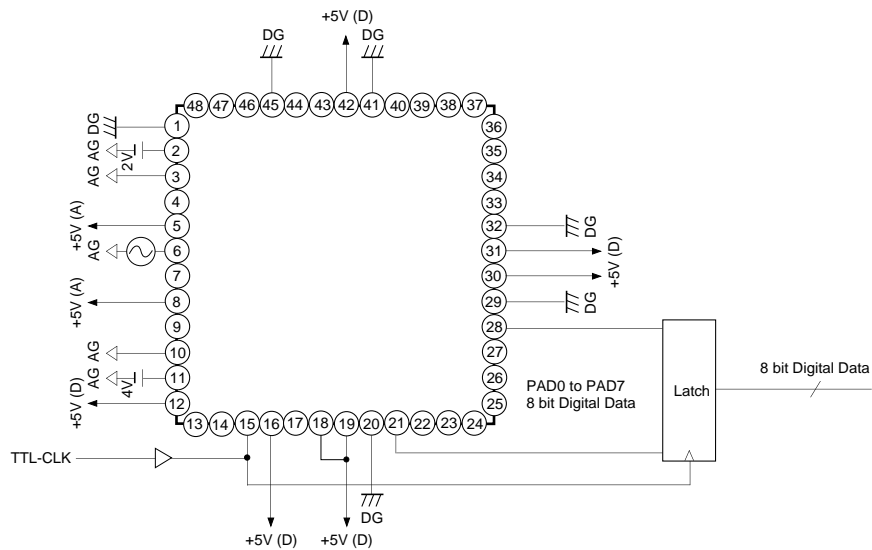

(4) Straight ECL input

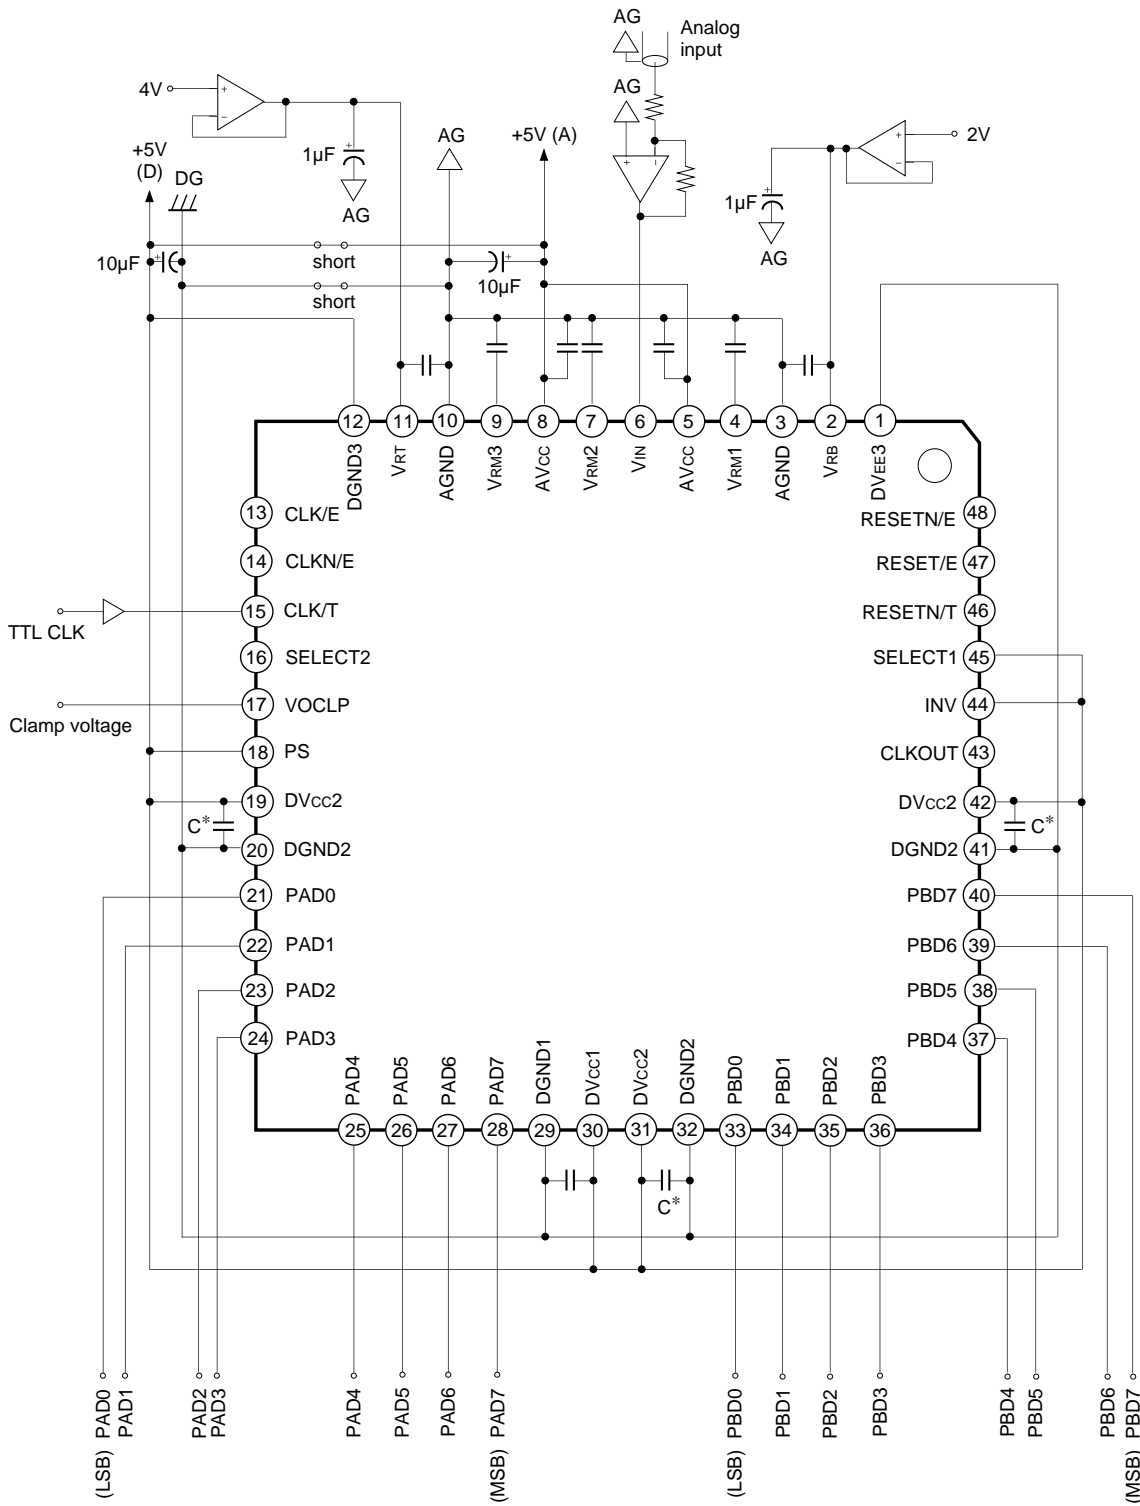

(5) Straight PECL input

(6) Straight TTL input

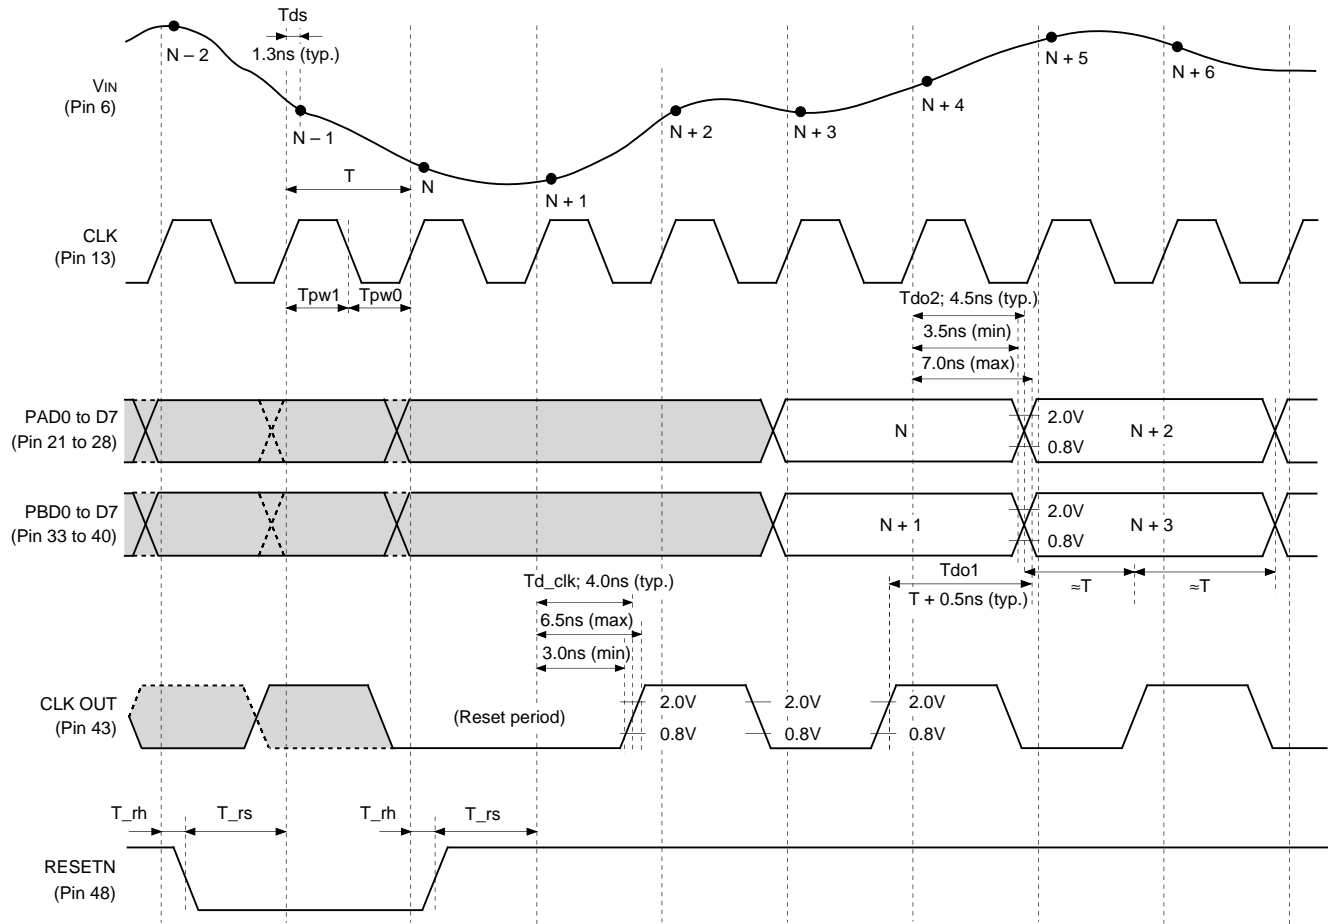

Application Circuit 2 DMUX Mode TTL I/O (When a single power supply is used)

- Short the analog system and digital system at one point immediately under the A/D converter. See the Notes on Operation.
- ||— is the chip capacitor of 0.1µF. Also, C* is important to suppress the noise generated during the TTL output circuit is operating. Place C* at the fixed position between the pins with the shortest distance.

Application circuits shown are typical examples illustrating the operation of the devices. Sony cannot assume responsibility for any problems arising out of the use of these circuits or for any infringement of third party patent and other right due to same.

DMUX Mode Timing Chart (Select = Vcc)

Straight Mode Timing Chart (Select = GND)

Notes on Operation

- The CXA3286R has the PECL and TTL input pins for the clock and reset input pins. When the clock is input in PECL level, inputting the reset signal in PECL level is recommended. Also, when the clock is input in TTL level, inputting the reset signal in TTL is recommended.
- The impedance of the input signal should be properly matched to ensure the CXA3286R's stable operation at the high speed.
- The power supply and grounding have a profound influence on converter performance. The power supply and grounding method are particularly important during high-speed operation. General points for caution are as follows.
 - The ground pattern should be as large as possible. It is recommended to make the power supply and ground patterns wider at an inner layer using a multi-layer board.
 - To prevent interference between AGND and DGND and between AVcc and DVcc, make sure the respective patterns are separated. To prevent a DC offset in the power supply pattern, connect the AVcc and DVcc lines at one point each via a ferrite-bead filter, etc. Shorting the AGND and DGND patterns in one place immediately under the A/D converter improves A/D converter performance.
 - Be sure to turn the analog and digital power supplies on simultaneously. If not simultaneously, the IC does not operate correctly.
 - Ground the power supply pins (AVcc, DVcc1, DVcc2, DVEE3) as close to each pin as possible with a 0.1 μ F or larger ceramic chip capacitor.
(Connect the AVcc pin to the AGND pattern and the DVcc1, DVcc2 and DVEE3 pins to the DGND pattern.)
 - It is recommended to place the ceramic chip capacitor of 0.1 μ F or more, in particular, between DVcc2 and DGND2 with the shortest distance. This has the effect to suppress the noise generated when the CXA3286R TTL output circuit operates.
 - The digital output wiring should be as short as possible. If the digital output wiring is long, the wiring capacitance will increase, deteriorating the output slew rate and resulting in reflection to the output waveform since the original output slew rate is quite fast.
- The analog input pin VIN has an input capacitance of approximately 10pF. To drive the A/D converter with the proper frequency response, it is necessary to prevent performance deterioration due to parasitic capacitance or parasitic inductance by using a large capacity drive circuit, keeping wiring as short as possible, and using chip parts for resistors and capacitors, etc.
- The VRT and VRB pins must have adequate by-pass to protect them from high-frequency noise. By-pass them to AGND with approximately 1 μ F tantal capacitor and 0.1 μ F chip capacitor as short as possible.
- If the CLKN/E pin is not used, by-pass this pin to DGND with an approximately 0.1 μ F capacitor. At this time, approximately DGND3 – 1.2V voltage is generated. However, this is not recommended for use as the threshold voltage VBB because it is too weak.

- When the digital input level is ECL or PECL level, ***/E** pins should be used and ***/T** pins left open. When the digital input level is TTL, ***/T** pins should be used and ***/E** pins left open.
- The CXA3286R TTL output high level is clamped to approximately 2.8 V in the IC. This makes it possible to directly interface with the 3.3V system CMOS IC. However, the CXA3286R has the VOCLP pin which is used to clamp the TTL output high level. See the Example of Representative Characteristics for the relationship between the VOCLP pin and the TTL high level.
- The CXA3026AQ has the output pins **P1**** and **P2****. However, in the CXA3286R, these symbols are changed as **PA**** and **PB****. At this time, the P1 side of the CXA3026AQ is changed to the PB side for the CXA3286R; the P2 side of the CXA3026AQ to the PA side for the CXA3286R.
- The pipeline delay of the CXA3286R is smaller by one clock, compared to that of CXA3026AQ.
