Intel[®] Pentium[®] III Processor Based on 0.13 Micron Process Up to 1.33 GHz

Datasheet

- Available at 1.0, 1.13, 1.20, 1.33 GHz. System bus frequency at 133 MHz
- 256 KB Advanced Transfer Cache (on-die, full speed Level 2 (L2) cache with Error Correcting Code (ECC))
- Dual Independent Bus (DIB) architecture: Separate dedicated external System Bus and dedicated internal high-speed cache bus
- Internet Streaming SIMD Extensions for enhanced video, sound and 3D performance
- Binary compatible with applications running on previous members of the Intel microprocessor line
- Dynamic execution micro architecture
- Data Prefetch Logic
- 8-way cache associativity provides improved cache hit rate on reads/store operations.

- Power Management capabilities
 —System Management mode
 - -Multiple low-power states
- Optimized for 32-bit applications running on advanced 32-bit operating systems
- Flip Chip Pin Grid Array (FC-PGA2) packaging technology; FC-PGA2 processors deliver high performance with improved handling protection and socketability
- Integrated high performance 16 KB instruction and 16 KB data, nonblocking, level one cache
- 256 KB Integrated Full Speed level two cache allows for low latency on read/store operations
- Quad Quadword Wide (256 bit) cache data bus provides extremely high throughput on read/ store operations.
- Error-correcting code for System Bus data

The Intel[®] Pentium[®] III processor based on 0.13 micron process is designed for high-performance desktops and for workstations and servers. It is binary compatible with previous Intel Architecture processors. The Pentium[®] III processor on 0.13 micron process provides great performance for applications running on advanced operating systems such as Windows* 98, Windows NT*, Windows* 2000, Windows Me*, Windows XP*, and Linux. This is achieved by integrating the best attributes of Intel processors—the dynamic execution, Dual Independent Bus architecture plus Intel MMXTM technology and Internet Streaming SIMD Extensions—bringing a new level of performance for systems buyers. The Pentium[®] III processor based on 0.13 micron process extends the power of the Pentium[®] III processors based on 0.13 micron process also include the latest features to simplify system management and lower the cost of ownership for large and small business environments. The Pentium[®] III processor based on 0.13 micron process offers great performance for today's and tomorrow's applications.

1.0 Introduction

The Intel[®] Pentium[®] III processor based on 0.13 micron process for the PGA370 socket is the next member of the P6 family, in the Intel IA-32 processor line and hereafter will be referred to as simply "the processor". The Pentium[®] III processor based on 0.13 micron process continues in the package technology called "flip-chip pin grid array" but contains an Integrated Heat Spreader (IHS) (see Figure 1). The flip-chip with IHS package will be labeled as FC-PGA2 and utilizes the same 370-pin zero insertion force socket (PGA370). Thermal solutions contact the IHS directly for the FC-PGA2 package and not to the bare-die as with the FC-PGA attachment.

The Pentium[®] III processor based on 0.13 micron process, like its predecessors in the P6 family of processors, implements a Dynamic Execution microarchitecture—a unique combination of multiple branch prediction, data flow analysis, and speculative execution. This enables these processors to deliver higher performance than the Intel Pentium processor, while maintaining binary compatibility with all previous Intel Architecture processors. The processor also executes Intel[®] MMXTM technology instructions for enhanced media and communication performance just as it's predecessor, the Intel Pentium III processor. Additionally, the Pentium III processor based on 0.13 micron process executes Streaming SIMD (single-instruction, multiple data) Extensions for enhanced floating point and 3-D application performance. Data Prefetch Logic adds functionality that anticipates the data needed by the application and pre-loads it into the Advanced Transfer Cache, further increasing processor and application performance. The processor utilizes multiple low-power states such as Sleep, and Deep Sleep to conserve power during idle times.

The processor includes an integrated on-die, 256 KB 8-way set associative level-two (L2) cache. The L2 cache implements the Advanced Transfer Cache Architecture with a 256-bit wide bus. The processor also includes a 16 KB level one (L1) instruction cache and 16 KB L1 data cache. These cache arrays run at the full speed of the processor core. The Pentium III processor based on 0.13 micron process for the PGA370 socket has a dedicated L2 cache bus, thus maintaining the dual independent bus architecture to deliver high bus bandwidth and performance. Memory is cacheable for 64 GB of addressable memory space, allowing significant headroom for desktop systems. Refer to the Specification Update document for this processor to determine the cacheability and cache configuration options for a specific processor. Contact your nearest Intel Sales Representative for the latest Processor Specification Update.

Figure 1. Integrated Heat Spreader (IHS)

The Pentium III processor based on 0.13 micron process supports a lower voltage differential and single-ended clocking for the system bus. The previous generation Intel[®] Pentium[®] III or Intel[®] Celeron[®] processors for the PGA370 socket will function in a Pentium III processor based on 0.13 micron process-supported platform, if that platform has been designed to be backward compatible. In addition, the Pentium III processor based on 0.13 micron process will not function in a previous generation platform due to incompatible system bus signal levels and clock type. Care must be taken to ensure the correct processors are installed in the correct PGA370 socket platforms.

1.1 Terminology

In this document, a '#' symbol after a signal name refers to an active low signal. This means that a signal is in the active state (based on the name of the signal) when driven to a low level. For example, when FLUSH# is low, a flush has been requested. When NMI is high, a nonmaskable interrupt has occurred. In the case of signals where the name does not imply an active state but describes part of a binary sequence (such as *address* or *data*), the '#' symbol implies that the signal is inverted. For example, D[3:0] = 'HLHL' refers to a hex 'A', and D[3:0]# = 'LHLH' also refers to a hex 'A' (H= High logic level, L= Low logic level).

The term "system bus" refers to the interface between the processor, system core logic (i.e., the chipset components), and other bus agents.

1.1.1 Package and Processor Terminology

The following terms are used often in this document and are explained here for clarification:

- Intel[®] Pentium[®] III Processor based on 0.13 micron process—The entire product including all internal components. Contains 256 KB of L2 cache and is uni-processor capable only.
- **PGA370 socket**—370-pin Zero Insertion Force (ZIF) socket which a FC-PGA packaged processor plugs into.
- **FC-PGA**—Flip Chip Pin Grid Array. The package technology used on Intel Pentium III processors based on 0.18 micron technology (CPUID=068xh) for the PGA370 socket. The FC-PGA package has the processor die exposed.
- FC-PGA2—Flip Chip Pin Grid Array 2. The package technology used on the Pentium III processor based on 0.13 micron process for the PGA370 socket. The FC-PGA2 package contains an Integrated Heat Spreader that covers the processor die.
- Advanced Transfer Cache (ATC)—L2 cache architecture used on the Pentium III processors based on 0.13 micron process. ATC consists of microarchitectural improvements that provide a higher data bandwidth interface into the processor core that is completely scaleable with the processor core frequency.
- **Keep-out zone**—The area on or near a FC-PGA packaged processor that system designs can not utilize.
- Keep-in zone—The area of a FC-PGA packaged processor that thermal solutions may utilize.
- **Processor**—For this document, the term processor is the generic form of the Pentium III processor based on 0.13 micron process for the PGA370 socket in the FC-PGA2 package.
- **Processor core**—The processor's execution engine.
- Integrated Heat Spreader (IHS)—The Integrated Heat Spreader (IHS) is a metal cover on the die and it is an integral part of the processor. The IHS promotes heat spreading away from the die backside to ease thermal constraints.

The cache and L2 cache are industry designated names.

1.1.2 Processor Naming Convention

Processor	Core Frequency (GHz)	System Bus Frequency (MHz)	L2 Cache Size (KBs)	L2 Cache Type ²	CPUID ¹
1A	1.00	133	256	ATC	06Bxh
1.13A	1.13	133	256	ATC	06Bxh
1.20	1.20	133	256	ATC	06Bxh
1.33	1.33	133	256	ATC	06Bxh

NOTES:

1. Refer to the Intel[®] Pentium[®] III Processor Specification Update for the exact CPUID for each processor.

 ATC = Advanced Transfer Cache. ATC is an L2 Cache integrated on the same die as the processor core. With ATC, the interface between the processor core and L2 Cache is 256-bits wide, runs at the same frequency as the processor core and has enhanced buffering.

2.0 Electrical Specifications

2.1 Processor System Bus and VREF

The Pentium III processor based on 0.13 micron process uses the original low voltage signaling of the Gunning Transceiver Logic (GTL) technology for the system bus. The GTL system bus operates at 1.25V signal levels versus GTL+ which operates at 1.5 V signal levels. The GTL+ signal technology is used by the Intel Pentium Pro, Intel Pentium II, and Intel Pentium III processors.

Current P6 family processors vary from the Intel Pentium Pro processor in their output buffer implementation. The buffers that drive the system bus signals on the Pentium III processor based on 0.13 micron process are actively driven to VTT for one clock cycle after the low to high transition to improve rise times. These signals are open-drain and require termination to a supply. Because this specification is different from the standard GTL specification, it is referred to as AGTL, or Assisted GTL in this and other documentation related to the Pentium III processor based on 0.13 micron process.

AGTL logic and AGTL+ logic are not compatible with each other due to differences with the signal switching levels. Pentium III processor based on 0.13 micron process cannot be installed into platforms where the chipset only supports the AGTL+ signal levels. For more information on AGTL or AGTL+ routing, refer to the appropriate platform design guide.

AGTL inputs use differential receivers that requires a reference voltage (VREF). VREF is used by the differential receivers to determine if the input signal is a logical 0 or a logical 1. The VREF signal is typically implemented as a voltage divider on the platform. Noise decoupling is critical for the VREF signal. Refer to the platform design guide for the recommended decoupling requirements. Another important item for the AGTL system bus is termination.

System bus termination is used to pull each signal to a high voltage level and to control reflections on the transmission line. The processor contains on-die termination resistors that provide termination for one end of the system bus. The other end of the system bus should also be terminated near the chipset by resistors placed on the platform or on-die termination within the chipset. It is recommended that the system bus is implemented using Dual-End Termination (DET) to meet the timings and signal integrity specified by the Pentium III processor based on 0.13 micron process. Figure 2 is a schematic representation of the AGTL bus topology for the Pentium III processor based on 0.13 micron.

Note: The RESET# signal requires a discrete external termination resistor on the system board.

The AGTL bus depends on incident wave switching. Therefore, timing calculations for AGTL signals are based on flight time as opposed to capacitive deratings. Analog signal simulations of the system bus, including trace lengths, is highly recommended especially when not following the recommended layout guidelines.

Note: Refer to appropriate design guide for platform specific termination.

2.2 Clock Control and Low Power States

Processors allow the use of Sleep, and Deep Sleep states to reduce power consumption by stopping the clock to internal sections of the processor, depending on each particular state. See Figure 3 for a visual representation of the processor low power states.

Figure 3. Stop Clock State Machine

For the processor to fully realize the low current consumption of the Stop-Grant, Sleep and Deep Sleep states, a Model Specific Register (MSR) bit must be set. For the MSR at 02Ah (Hex), bit 26 must be set to a 1 (this is the power on default setting) for the processor to stop all internal clocks during these modes. For more information, see the *Intel Architecture Software Developer's Manual, Volume 3: System Programming Guide*.

2.2.1 Normal State—State 1

This is the normal operating state for the processor.

2.2.2 AutoHALT Powerdown State—State 2

AutoHALT is a power state entered when the processor executes the HALT instruction. The processor transitions to the Normal state upon the occurrence of SMI#, INIT#, or LINT[1:0] (NMI, INTR). RESET# causes the processor to immediately initialize itself.

The return from a System Management Interrupt (SMI) handler can be to either Normal Mode or the AutoHALT Power Down state. See the *Intel Architecture Software Developer's Manual, Volume III: System Programmer's Guide* for more information.

FLUSH# is serviced during the AutoHALT state, and the processor will return to the AutoHALT state.

The system can generate a STPCLK# while the processor is in the AutoHALT Power Down state. When the system deasserts the STPCLK# interrupt, the processor returns execution to the HALT state.

2.2.3 Stop-Grant State—State 3

The Stop-Grant state on the processor is entered when the STPCLK# signal is asserted.

Since the AGTL signal pins receive power from the system bus, these pins should not be driven (allowing the level to return to VTT) for minimum power drawn by the termination resistors in this state. In addition, all other input pins on the system bus should be driven to the inactive state.

BINIT# and FLUSH# are not serviced during the Stop-Grant state.

RESET# causes the processor to immediately initialize itself, but the processor stays in Stop-Grant state. A transition back to the Normal state occurs with the deassertion of the STPCLK# signal.

A transition to the HALT/Grant Snoop state occurs when the processor detects a snoop on the system bus (see Section 2.2.4). A transition to the Sleep state (see Section 2.2.5) occurs with the assertion of the SLP# signal.

While in Stop-Grant State, SMI#, INIT#, and LINT[1:0] are latched by the processor, and only serviced when the processor returns to the Normal state. Only one occurrence of each event is recognized and serviced upon return to the Normal state.

2.2.4 HALT/Grant Snoop State—State 4

The processor responds to snoop transactions on the system bus while in Stop-Grant state or in AutoHALT Power Down state. During a snoop transaction, the processor enters the HALT/Grant Snoop state. The processor stays in this state until the snoop on the system bus has been serviced (whether by the processor or another agent on the system bus). After the snoop is serviced, the processor returns to the Stop-Grant state or AutoHALT Power Down state, as appropriate.

2.2.5 Sleep State—State 5

The Sleep state is a very low power state in which the processor maintains its context, maintains the phase-locked loop (PLL), and has stopped all internal clocks. The Sleep state can only be entered from the Stop-Grant state. Once in the Stop-Grant state, the SLP# pin can be asserted, causing the processor to enter the Sleep state. The SLP# pin is not recognized in the Normal or AutoHALT states.

Snoop events that occur while in Sleep State or during a transition into or out of Sleep state cause unpredictable behavior.

In the Sleep state, the processor is incapable of responding to snoop transactions or latching interrupt signals. No transitions or assertions of signals (with the exception of SLP# or RESET#) are allowed on the system bus while the processor is in Sleep state. Any transition on an input signal before the processor has returned to Stop-Grant state will result in unpredictable behavior.

If RESET# is driven active while the processor is in the Sleep state, and held active as specified in the RESET# pin specification, then the processor will reset itself, ignoring the transition through Stop-Grant State. If RESET# is driven active while the processor is in the Sleep State, the SLP# and STPCLK# signals should be deasserted immediately after RESET# is asserted to ensure the processor correctly executes the reset sequence.

While in the Sleep state, the processor is capable of entering its lowest power state, the Deep Sleep state, by stopping the BCLK input (see Section 2.2.6). Once in the Sleep state, the SLP# pin can be deasserted if another asynchronous system bus event occurs. The SLP# pin has a minimum assertion of one BCLK period.

2.2.6 Deep Sleep State—State 6

The Deep Sleep state is the lowest power state the processor can enter while maintaining context. The Deep Sleep state is entered by stopping the BCLK input (after the Sleep state was entered from the assertion of the SLP# pin). The processor is in Deep Sleep state immediately after BCLK is stopped. BCLK and BCLK# have to be separated by at least 0.2 V during the Deep Sleep State. Stopping of the BCLK input lowers the overall current consumption to leakage levels.

To re-enter the Sleep state, the BCLK input must be restarted. A period of 1 ms (to allow for PLL stabilization) must occur before the processor can be considered to be in the Sleep state. Once in the Sleep state, the SLP# pin can be deasserted to re-enter the Stop-Grant state.

While in Deep Sleep state, the processor is incapable of responding to snoop transactions or latching interrupt signals. No transitions or assertions of signals are allowed on the system bus while the processor is in Deep Sleep state. Any transition on an input signal before the processor has returned to Stop-Grant state will result in unpredictable behavior.

Table 2. System Bus Clock in Deep Sleep Mode (Differential Mode only)¹

Symbol	Parameter	Min	Max	Units	Notes
V _{BCLK}	BCLK Voltage Level when not active	0.4	1.45	V	2
V _{BCLK} –V _{BCLK#}	BCLK# Voltage Level when not active	0	V _{BCLK - 0.2}	V	2

NOTES:

1. The values in this table are based on differential probe measurement of the BCLK.

 The DC voltage level specified must be maintained when the system bus clock is not active (e.g., Deep Sleep Mode). V_{BCLK#} has to be 200 mV less than V_{BCLK.}

2.2.7 Clock Control

BCLK provides the clock signal for the processor and on-die L2 cache. During AutoHALT Power Down and Stop-Grant states, the processor will process a system bus snoop. The processor does not stop the clock to the L2 cache during AutoHALT Power Down or Stop-Grant states. Entrance into the Halt/Grant Snoop state allows the L2 cache to be snooped, similar to the Normal state.

When the processor is in Sleep and Deep Sleep states, it does not respond to interrupts or snoop transactions. During the Sleep state, the internal clock to the L2 cache is not stopped. During the Deep Sleep state, the internal clock to the L2 cache is stopped. The internal clock to the L2 cache is restarted only after the internal clocking mechanism for the processor is stable (i.e., the processor has re-entered Sleep state).

PICCLK should not be removed during the AutoHALT Power Down or Stop-Grant states. PICCLK can be removed during the Sleep or Deep Sleep states. When transitioning from the Deep Sleep state to the Sleep state, PICCLK must be restarted with BCLK.

2.3 Power and Ground Pins

The operating voltage for the Pentium III processor based on 0.13 micron process is the same for the core and the L2 cache. VCC_{CORE} is defined as the power pins that supply voltage to the processor's core and cache. The Voltage Regulator Module (VRM) or Voltage Regulator are controlled by the five voltage identification (VID) signals driven by the processor. The VID signals specify the voltage required by the processor core. Refer to Section 2.6 for further details on the VID voltage settings.

The Pentium III processor based on 0.13 micron process has 74 VCC_{CORE}, 7 VREF, 20 VTT, VCC_{CMOS1.5}, VCC_{CMOS1.8}, VCC_{CMOS2.0} and 74 VSs inputs. The VREF inputs are used as the AGTL reference voltage for the processor. The VTT inputs (1.25V) are used to provide an AGTL termination voltage to the processor. VCC_{CMOS1.5} and VCC_{CMOS1.8} and VCC_{CMOS2.0} are not voltage input pins to the processor but rather voltage sources for the pullup resistors which are connected to CMOS (non-AGTL) input/output signals driven to/from the processor. The Vss inputs are ground pins for the processor core and L2 cache.

On the platform, all VCC_{CORE} pins must be connected to a voltage island (an island is a portion of a power plane that has been divided, or an entire plane) to minimize any voltage drop that may occur due to trace impedance. It is also highly recommended for the platform to provide either a voltage island or a wide trace for the VTT pins. Similarly, all Vss pins must be connected to a system ground plane. These recommendations can be found in the platform design guide layout section.

2.3.1 Phase Lock Loop (PLL) Power

It is highly critical that phase lock loop power delivery to the processor meets Intel's requirements. A low pass filter is required for power delivery to pins PLL1 and PLL2. This serves as an isolated, decoupled power source for the internal PLL. Refer to the Phase Lock Loop Power section in the appropriate platform design guide for the recommended filter implementation.

2.4 Decoupling Guidelines

Due to the large number of transistors and high internal clock speeds, the processor is capable of generating large average current swings between low and full power states. The fluctuations can cause voltages on power planes to sag below their nominal values if bulk decoupling is not adequate. Care must be taken in the board design to ensure that the voltage provided to the processor remains within the specifications listed in Table 7. Failure to do so can result in timing violations (in the event of a voltage sag) or a reduced lifetime of the component (in the event of a voltage overshoot).

2.4.1 Processor VCC_{CORE} Decoupling

The regulator for the VCC_{CORE} input must be capable of delivering the dICC_{CORE}/dt (defined in Table 7) while maintaining the required tolerances (also defined in Table 7). Failure to meet these specifications can result in timing violations (during VCC_{CORE} sag) or a reduced lifetime of the component (during VCC_{CORE} overshoot).

The processor requires both high frequency and bulk decoupling on the system motherboard for proper AGTL bus operation. The minimum recommendation for the processor decoupling requirement is listed below. All capacitors should be placed next to and within the PGA370 socket cavity and mounted on the primary side of the motherboard. The capacitors are arranged to minimize the overall inductance between the VCC_{CORE} and Vss power pins.

Decoupling Recommendations

- VCC_{CORE} decoupling: A minimum of sixteen 4.7 uF capacitors in a 1206 package.
- VTT decoupling: Twenty 0.1 uF capacitors in 0603 packages.
- VREF decoupling: 0.1 uF and 0.001 uF capacitors in 0603 package placed near the VREF pins.

For additional decoupling requirements, refer to the appropriate platform design guide for recommended capacitor component value/quantity and placement.

2.5 Processor System Bus Clock and Processor Clocking

The Intel Pentium III processor based on 0.13 micron process will implement an auto-detect mechanism that will allow the processor to use either single-ended or differential signaling for the system bus and processor clocking. The processor checks to see if the signal on pin Y33 is toggling. If this signal is toggling, the processor operates in differential mode. Refer to Figure 5 for an example on differential clocking. Resistor values and clock topology are listed in the appropriate platform design guide for a differential implementation.

Note: References to BCLK throughout this document also imply to it's complement signal, BCLK# in differential implementations, and when noted otherwise.

Since legacy PGA370 socket platforms use a different single-ended clocking specification than the Pentium III processor based on 0.13 micron process, the Pentium III processor based on 0.13 micron process will not function when placed into these platforms. The BCLK input directly controls the operating speed of the system bus interface. All AGTL system bus timing parameters are specified with respect to the crossing point of the rising edge of the BCLK and the falling edge of BCLK# inputs in a differential implementation. See the *P6 Family of Processors Hardware Developer's Manual* for further details. The reference voltage of the BCLK in the *P6 Family of Processors Hardware Developer Manual* is re-defined as the crossing point of the BCLK and BCLK# in a differential implementation.

Figure 5. Differential/Single-Ended Clocking Example

intel®

2.6 Voltage Identification

There are five voltage identification (VID) pins on the PGA370 socket. These pins can be used to support automatic selection of VCC_{CORE} voltages. The VID pins for the Pentium III processor based on 0.13 micron process are open drain signals versus opens or shorts found on the previous Intel Pentium III FC-PGA processor. Refer to Table 11 for level specifications for the VID signals. This pull-up resistor may be either external logic on the motherboard or internal to the Voltage Regulator.

The VID signals rely on a 3.3 V pull-up resistor to set the signal to a logic high level. The VID pins are needed to fully support voltage specification variations on current and future processors. The voltage selection range for the processor is defined in Table 3. The VID25mV signal is a new signal that allows the voltage regulator or voltage regulator module (VRM) to output voltage levels in 25 mV increment necessary for the Pentium III processor based on 0.13 micron process only. The current Pentium III processor in the FC-PGA package will not have this VID25mV signal. The VID25mV pin location is actually a Vss pin on the model 68xh Pentium III processor. By connecting the VID25mV signal to the Vss pin, it will disable the 25mV stepping granularity output and the regulator will resort to 50 mV stepping increment. The voltage regulator or VRM must supply the voltage that is requested or disable itself.

In addition to the new signal "VID25mV", the Pentium III processor based on 0.13 micron process will introduce a second new signal labeled as "VTT_PWRGD". The VTT_PWRGD signal informs the platform that the VID and BSEL signals are stable and should be sampled. During Power-up, the VID signals will be in an indeterminate state for a small period of time. The voltage regulator or the VRM should not latch the VID signals until the VTT_PWRGD signal is asserted by the VRM and sampled active. The assertion of the VTT_PWRGD signal indicates the VID signals are stable and are driven to the final state by the processor. Refer to Figure 14 for power-up timing sequence for the VTT_PWRGD and the VID signals.

/ID25mV	VID3	VID2	VID1	VID0	Vcc _{CORE}

1	0	1	0	1	1.825

 Table 3.
 Voltage Identification Definition ¹

NOTES:

1. 0 = Processor pin connected to Vss.

1 = Open on processor; may be pulled up to TTL VIH (3.3V max) on baseboard.

The VID pins should be pulled up to a 3.3 V level. This may be accomplished with pull-ups internal to the voltage regulator, which ensures valid VID pull-up voltage during Power-up and Power-down sequences. If external resistors are used for the VID[3:0, 25mV] signal, the power source must be guaranteed to be stable when the supply to the voltage regulator is stable. This prevents the possibility of the processor supply going above the specified VCC_{CORE} in the event of a failure in the supply for the VID lines. In the case of a DC-to-DC converter, this can be accomplished by using the input voltage to the converter for the VID line pull-ups. A resistor equal to 1 K Ω may be used to connect the VID signals to the voltage regulator input.

Note: Intel requires that designs utilize VRM 8.5 and not VRM 8.4 specifications to meet the Pentium III processor based on 0.13 micron process requirements.

To re-emphasize, VRM 8.5 introduces two new signals [VID25mV and VTT_PWRGD] that is utilized by the Pentium III processor based on 0.13 micron process and platform. Ignoring and not connecting these two new pins, as documented in the Platform Design Guidelines, will prevent the Pentium III processor based on 0.13 micron process from operating at the specified voltage levels and core frequency. Figure 6 provides a high-level interconnection schematic. Refer to the *VRM* 8.5 DC-DC Converter Design Guideline and the appropriate Platform Design Guidelines for further detailed information on the voltage identification and bus select implementation. Refer to Figure 14 for VID power-up sequence and timing requirements.

2.7 Processor System Bus Unused Pins

All RESERVED pins must remain unconnected unless specifically noted. Connection of these pins to VCC_{CORE}, VREF, VSS, VTT or to any other signal (including each other) can result in component malfunction or incompatibility with future processors. See Section 5.4 for a pin listing of the processor and the location of each RESERVED pin.

PICCLK must be driven with a valid clock input and the PICD[1:0] signals must be pulled-up to V_{CC} will not be used. A separate pull-up resistor must be provided for each PICD signal.

For reliable operation, always connect unused inputs or bidirectional signals to their deasserted signal level. The pull-up or pull-down resistor values are system dependent and should be chosen such that the logic high (V_{IH}) and logic low (V_{IL}) requirements are met. See Table 11 for level specifications of non-AGTL signals.

For unused AGTL inputs, the on-die termination will be sufficient. No external R_{TT} is necessary on the motherboard.

For unused CMOS inputs, active low signals should be connected through a pull-up resistor to $V_{CC}C_{MOS1.5}$ and meet V_{IH} requirements. Unused active high CMOS inputs should be connected through a pull-down resistor to ground (VSS) and meet V_{IL} requirements. Unused CMOS outputs can be left unconnected. A resistor must be used when tying bidirectional signals to power or ground. When tying any signal to power or ground, a resistor will also allow for system testability.

2.8 Processor System Bus Signal Groups

To simplify the following discussion, the processor system bus signals have been combined into groups by buffer type. All P6 family processor system bus outputs are open drain and require a high-level source provided termination resistors. However, the Pentium III processor based on 0.13 micron process includes on-die termination for AGTL signals and termination resistors placed on the platform are not necessary except for the RESET# signal which still requires external termination.

AGTL input signals have differential input buffers which use VREF as a reference signal. AGTL output signals require termination to 1.25 V. In this document, the term "AGTL Input" refers to the AGTL input group as well as the AGTL I/O group when receiving. Similarly, "AGTL Output" refers to the AGTL output group as well as the AGTL I/O group when driving.

The PWRGOOD signal input is a 1.8 V signal level and must be pulled up to VCC_{CMOS1.8}. The VTT_PWRGD is **not** 1.8 V tolerant and must be connected to VTT (1.25 V) Other CMOS inputs (A20M#, IGNNE#, INIT#, LINT0/INTR, LINT1/NMI, PREQ#, SMI, SLP#, and STPCLK#) are only 1.5 V tolerant and must be pulled up to VCC_{CMOS1.5}. The CMOS, APIC, and TAP outputs are open drain and must be pulled to the appropriate level to meet the input specifications of the interfacing device.

The groups and the signals contained within each group are shown in Table 4. Refer to Section 7.0 for a description of these signals.

Table 4. System Bus Signal Groups ¹

Group Name	Signals		
AGTL Input	BPRI#, DEFER#, RESET#, RSP#		
AGTL Output	PRDY#		
AGTL I/O	A[35:3]#, ADS#, AERR#, AP[1:0]#, BERR#, BINIT#, BNR#, BP[3:2]#, BPM[1:0]#, BR0# ² , D[63:0]#, DBSY#, DEP[7:0]#, DRDY#, HIT#, HITM#, LOCK#, REQ[4:0]#, RP#, RS[2:0]#, TRDY#		
CMOS Input (1.25 V) ³	VTT_PWRGD		
CMOS Input (1.5 V) ⁴	A20M#, FLUSH#, IGNNE#, INIT#, LINT0/INTR, LINT1/NMI, PREQ#, SLP#, SMI#, STPCLK#		
CMOS Input (1.8 V) ⁵	PWRGOOD		
CMOS Output (1.5 V) ⁴	FERR#, IERR#, THERMTRIP#		
CMOS Output ⁸ (3.3 V)	VID[3:0,25mV], BSEL[1:0]		
System Bus Clock ¹⁰ (1.25 V / 2.5 V)	BCLK0, BCLK0#		
APIC Clock ⁹	PICCLK		
APIC I/O ⁴	PICD[1:0]		
TAP Input ⁴	TCK, TDI, TMS, TRST#		
TAP Output ⁴	TDO		
Power/Other ⁶	CPUPRES#, DYN_OE, NCHTRL, PLL[2:1], SLEWCTRL, RTTCTRL ⁷ , THERMDN, THERMDP, VCC _{CORE} , VREF, VSS, VTT, Reserved,		

NOTES:

- 1. See Section 7.0 for information on the these signals.
- 2. The BR0# pin is the only BREQ# signal that is bidirectional. See Section 7.0 for more information.
- 3. This signal is 1.25 V.
- 4. These signals are 1.5 V.
- 5. This signal is 1.8 V.
- 6. V_{CC}_{CORE} is the power supply for the processor core and is described in Section 2.6. VID[3:0,25mV] is described in Section 2.6.

 - VTT is used to terminate the system bus and generate VREF on the motherboard.
 - Vss is system ground.
 - BSEL[1:0] is described in Section 2.8.2 and Section 7.0.
 - All other signals are described in Section 7.0.
- 7. This signal is used to control the value of the processor on-die termination resistance. Refer to the platform design guide for the recommended pulldown resistor value.
- 8. These signals are 3.3 V.
- 9. These signals are 2.0 V.
- 10. 1.25 V signal for differential clock application and 2.5V for Single-ended clock application.

2.8.1 Asynchronous vs. Synchronous for System Bus Signals

All AGTL signals are synchronous to BCLK (BCLK/BCLK#). All of the CMOS, Clock, APIC, and TAP signals can be applied asynchronously to BCLK (BCLK/BCLK#). All APIC signals are synchronous to PICCLK. All TAP signals are synchronous to TCK.

2.8.2 System Bus Frequency Select Signals

The System Bus Frequency Select Signals (BSEL [1:0]) are used to select the system bus frequency for the Pentium III processor based on 0.13 micron process. The BSEL signals are also used by the chipset and system bus clock generator. The BSEL pins for the Pentium III processor based on 0.13 micron process are open drain signals versus opens or shorts found on the previous Intel

Pentium III FC-PGA processor. Refer to Table 11 for level specifications for the BSEL signals.

The BSEL signals rely on a 3.3 V pull-up resistor to set the signal to a logic high level. Similar to the VID signals described in Section 2.6, the VTT_PWRGD signal also informs the platform that the BSEL signals are stable and should be sampled. During Power-up, the BSEL signals will be in a indeterminate state for a small period of time. The chipset or system bus clock generator should not sample and/or latch the BSEL signals until the VTT_PWRGD signal is asserted. The assertion of the VTT_PWRGD signal indicates the BSEL signals are stable and are driven to the final state by the processor. Refer to Figure 14 for power-up timing sequence for the VTT_PWRGD and the BSEL signals.

Table 5 defines the possible combinations of the BSEL signals and the frequency associated with each combination. The frequency selection is determined by the processor(s) and driven out to the chipset and system bus clock generator. All system bus agents must operate at the same frequency determined by the processor. The Pentium III processor based on 0.13 micron process operates at 133 MHz system bus frequency based on the system bus specified rating marked on the package. Over or under-clocking the system bus frequency outside the specified rating marked on the package is not recommended.

Figure 7. BSEL[1:0] Example for a System Design

Table 5. Frequency Select Truth Table for BSEL[1:0]

BSEL1	BSEL0	Frequency
0	0	Reserved
0	1	Reserved
1	0	Reserved
1	1	133 MHz

2.9 Test Access Port (TAP) Connection

Due to the voltage levels supported by other components in the Test Access Port (TAP) logic, it is recommended that the processor be first in the TAP chain and followed by any other components within the system. A translation buffer should be used to connect to the rest of the chain unless one of the other components is capable of accepting an input of the appropriate voltage. Similar considerations must be made for TCK, TMS, and TRST#. Two copies of each signal may be required with each driving a different voltage level.

2.10 Maximum Ratings

Table 6 contains processor stress ratings only. Functional operation at the absolute maximum and minimum is not implied nor guaranteed. The processor should not receive a clock while subjected to these conditions. Functional operating conditions are given in the timing and level tables in Section 2.11 through Section 2.13. Extended exposure to the maximum ratings may affect device reliability. Furthermore, although the processor contains protective circuitry to resist damage from static electric discharge, one should always take precautions to avoid high static voltages or electric fields.

Table 6. Absolute Maximum Ratings

Symbol	Parameter	Min	Max	Unit	Notes
TSTORAGE	Processor storage temperature	-40	85	°C	
$V_{\rm CC}{}_{\rm CORE}$ and $V_{\rm TT}$	Processor core voltage and termination supply voltage with respect to VSS	0.5	1.75	V	
Vin _{AGTL}	AGTL buffer input voltage	-0.3	1.78	V	1, 3
Vin _{CMOS} 1.5	CMOS buffer DC input voltage with respect to VSS	-0.3	2.08	V	2, 3, 4
$VVID \And VBSEL$	Max VID and BSEL pin current	-0.3	3.6	V	

NOTES:

1. Input voltage can never exceed Vss +1.78 volts.

2. Input voltage can never exceed VSS + 2.08 volts.

3. Input voltage can never go below -0.3 V

4. Parameter applies to CMOS, APIC, and TAP bus signal groups only.

2.11 Processor Voltage Level Specifications

The processor voltage level specifications in this section are defined at the PGA370 socket pins (bottom side of the motherboard). See Section 7.0 for the processor signal descriptions and Section 5.4 for the signal listings.

Most of the signals on the processor system bus are in the AGTL signal group. These signals are specified to be terminated to 1.25 V. The voltage level specifications for these signals are listed in Table 10 on page 29.

To allow connection with other devices, the clock, CMOS, APIC, and TAP signals are designed to interface at non-AGTL levels. The voltage level specifications for these pins are listed in Table 11 on page 29.

Table 7 through Table 13 list the voltage level specifications for the Pentium III processor based on 0.13 micron process. Specifications are valid only while meeting specifications for junction temperature, clock frequency, and input voltages. Care should be taken to read all notes associated with each parameter.

Symbol	Parameter	Core Freq	Min	Тур	Мах	Unit	Notes
VCCCORE	Vcc for processor core	1.00 GHz 1.13 GHz 1.20 GHz 1.33 GHz		1.475 1.475 1.475 1.5		v	3
VTT	Static AGTL bus termination voltage			1.25		V	1.25 ±3% ^{, 4}

dl _{vTT} /dt	Termination current slew rate				Table 13	A/ µs	8, 9, 10, See Table 13

Table 7. Voltage and Current Specifications ^{1, 2}

NOTES:

Unless otherwise noted, all specifications in this table apply to all processor frequencies.
 All specifications in this table apply only to the Intel[®] Pentium[®] III processor based on 0.13 micron process.

3. Vcc_{CORE} and lcc_{CORE} supply the processor core and the on-die L2 cache. 4. VTT must be held to 1.25 V \pm 9% while the AGTL bus is active. It is required that VTT be held to 1.25 V \pm 3% while the processor system bus is static (idle condition). The ±3% range is the required design target; ±9%

will come from the transient noise added. This is measured at the PGA370 socket pins on the bottom side of the baseboard.

- 5. These are the tolerance requirements, across a 20 MHz frequency bandwidth, measured at the processor socket pin on the soldered-side of the motherboard. VCCCORF must return to within the static voltage specification within 100 µs after a transient event; see the VRM 8.5 DC-DC Converter Design Guidelines for further details.
- 6. Maximum Icc is measured at Vcc typical voltage and under a maximum signal loading conditions.
- 7. The current specified is also for AutoHALT state.
- 8. Maximum values are specified by design/characterization at nominal Vcc_{CORE}.
 9. Based on simulation and averaged over the duration of any change in current. Use to compute the maximum inductance tolerable and reaction time of the voltage regulator. This parameter is not tested.
- 10.dlcc/dt specifications are measured and specified at the PGA370 socket pins.
- 11. Static voltage regulation includes: DC output initial voltage set point adjust, Output ripple and noise, Output load ranges specified in the tables above. See VRM 8.5 Specification.
- 12. Pull ups only.
- 13. For processors with VCC_{CORE} of 1.475 V.
- 14. For processors with VCC_{CORE} of 1.5 V.

Table 8. Power Supply Current Slew Rate (dlcc_{core}/dt)

Table 8 contains typical slew rate data for the Pentium III processor based on 0.13 micron process. Actual slew rate values and wave-shapes may vary slightly depending on the type and size of decoupling capacitors used in a particular implementation.

	Vo	Itage Deviation fi	rom VID Setting (n	ιV)
	Static To	olerance	Transient	Tolerance

Figure 8. Vcc Static and Transient Tolerance

Table 10. AGTL Signal Group Levels Specifications ¹

Symbol	Parameter	Min	Мах	Unit	Notes
VIL	Input Low Voltage		Vref – 0.200	V	6
Vih	Input High Voltage	VREF + 0.200		V	2, 3, 6
Ron	Buffer On Resistance		16.67	Ω	5
IL.	Leakage Current for inputs, outputs, and I/O		±100	μA	4, 7

NOTES:

1. Unless otherwise noted, all specifications in this table apply to Intel[®] Pentium[®] III processors based on 0.13 micron process at all frequencies.

2. All inputs, outputs, and I/O pins must comply with the signal quality specifications in Section 3.0.

3. Minimum and maximum VTT are given in Table 13 on page 30.

4. $(0 \le VIN \le 1.25 V + 3\%)$ and $(0 \le VOUT \le 1.25 V + 3\%)$.

5. Refer to the processor I/O Buffer Models for I/V characteristics.

6. Steady state input voltage must not be above Vss + 1.65 V or below VTT - 1.65 V.

7. Does not apply to Vcc leakage current due to the presence of on-die RTT.

Table 11. Non-AGTL Signal Group Levels Specifications¹

Ilo	Output Leakage Current		±100	μA	3, 4, 6, 7

NOTES:

1. Unless otherwise noted, all specifications in this table apply to Intel[®] Pentium[®] III processors based on 0.13 micron process at all frequencies.

2. Parameter measured at 9 mA (for use with TTL inputs).

3. $(0 \le VIN \le 1.8 V + 10\%)$.

4. $(0 \le VOUT \le 1.8 V + 10^{\circ})$.

5. For BCLK specifications, refer to Table 24 on page 42.

6. $(0 \le VIN \le 1.5 V + 10\%)$.

7. ($0 \le VOUT \le 1.5 \lor +10\%$). 8. Applies to non-AGTL signal PWRGOOD.

9. Applies to non-AGTL signal PICCLK.

10.Applies to non-AGTL signals except BCLK, PICCLK, and PWRGOOD.

11. Applies to non-AGTL signal VTT_PWRGD.

12.Vcmos_ref = 2/3 Vcc_cmos1.5, refer to Table 7 on page 26.

13. Applies to PICD[1:0] only

Symbol	Parameter	Min	Мах	Unit	Notes
V	Nominal Voltage		3.45	V	3.3 + 5%
Voн	Output High Voltage		0.9	V	
Ilo	Output Leakage Current		100	μA	

Table 12. 3.3 Volt CMOS Output Signal Group DC Specifications

2.12 AGTL System Bus Specifications

It is recommended that the AGTL bus be routed in a daisy-chain fashion with termination resistors to VTT. These termination resistors are placed electrically between the ends of the signal traces and the VTT voltage supply. The valid high and low levels are determined by the input buffers using a reference voltage called VREF. Refer to the appropriate platform design guide for more information.

Table 13 lists the nominal specification for the AGTL termination voltage (VTT). The AGTL reference voltage (VREF) is generated on the system motherboard and should be set to 2/3 VTT for the processor and other AGTL logic. It is important that the baseboard impedance be specified and held to a $\pm 15\%$ tolerance, and that the intrinsic trace capacitance for the AGTL signal group traces is known and well-controlled. For more details on the AGTL buffer specification, see the *Intel*[®] *Pentium*[®] *II Processor Developer's Manual* and AP-585, *Intel*[®] *Pentium*[®] *II Processor AGTL Guidelines*.

Table 13. Processor AGTL Bus Specifications ^{1, 2}

Symbol	Parameter	Min	Тур	Мах	Units	Notes
Vtt	Bus Termination Voltage	1.1375	1.25		V	3
On-die R _{TT}	Termination Resistor	50	56 68	115	Ω	4
Vref	Bus Reference Voltage		2/3VTT		V	5

NOTES:

- 1. Unless otherwise noted, all specifications in this table apply to Intel[®] Pentium[®] III processors based on 0.13 micron process at all frequencies.
- 2. Pentium III processors based on 0.13 micron process for the PGA370 socket contain AGTL termination resistors on the processor die, except for the RESET# input.
- 3. V⊤T must be held to 1.25 V ±9%. It is required that V⊤T be held to 1.25 V ±3% while the processor system bus is idle (static condition). This is measured at the PGA370 socket pins on the bottom side of the baseboard.
- 4. Uni-processor platforms require a 56 Ω resistor and dual-processor platforms require a 68 Ω resistor. Tolerance for on-die RTT is ±10% (56, 68 Ω resistors). RTT is ±15% (100 Ω resistors).

5. VREF is generated on the motherboard and should be 2/3 VTT ±5% nominally. Insure that there is adequate VREF decoupling on the motherboard.

2.13 System Bus Timing Specifications

The processor system bus timings specified in this section are defined at the socket pins on the bottom of the motherboard. Unless otherwise specified, timings are tested at the processor pins during manufacturing. Timings at the processor pins are specified by design characterization. See Section 7.0 for the processor signal definitions.

Table 14 through Table 21 list the timing specifications associated with the processor system bus. These specifications are broken into the following categories: Table 14 contains the system bus clock specifications for Single-ended clock mode operation and Table 15 contains the system bus clock specifications for Differential clock mode operation. Table 17 contains the AGTL specifications, Table 18 contains the CMOS signal group specifications, Table 19 contains timings for the reset conditions, Table 20 covers APIC bus timing, and Table 21 covers TAP timing.

All processor system bus timing specifications for the AGTL signal group are relative to the rising edge of the BCLK input. All AGTL timings are referenced to VREF for both 0 and 1 logic levels unless otherwise specified.

The timings specified in this section should be used in conjunction with the I/O buffer models provided by Intel. These I/O buffer models, which include package information, are available for the Pentium III processor based on 0.13 micron process in the FC-PGA2 package in IBIS* 3.1 model format (Electronic Format).

AGTL layout guidelines are also available in the appropriate platform design guide. Care should be taken to read all notes associated with a particular timing parameter.

Table 14. System Bus Timing Specifications (Single-Ended Clock)^{1,4}

	133	MHz	100 MHz				
T# Parameter	Min	Max	Min	Max	Unit	Figure	Notes
T1: BCLK Period - average	7.5	7.65	10.0	10.15	ns	9	2
T1 _{abs} : BCLK Period - Instantaneous minimum	7.25		9.75		ns		2
T2: BCLK Period Stability		250		250	ps		2
T5: BCLK Rise Time	0.4	1.6	0.4	1.6	ns	10	3
T6: BCLK Fall Time	0.4	1.6	0.4	1.6	ns	10	3
T3: BCLK High Time	1.4		2.5		ns	10	5
T4: BCLK Low Time	1.4		2.4		ns	10	6
T7: BCLK Input High	2.2		2.2		V		
T8: BCLK Input Low		0.3		0.3	V		

NOTES:

- Unless otherwise noted, all specifications in this table apply to Intel[®] Pentium[®] III processors based on 0.13 micron process at all frequencies.
- 2. Period, jitter, offset and skew measured at 1.25 V.
- 3. Measured from 0.5 to 2.0 V.
- CLKREF (BCLK#) = 1.25 V with ± 5% DC tolerance. CLKREF must be generated from a stable source. AC tolerances must be less than -40 dB @ 1 MHz.
- 5. BCLK High Time is measured above 2.0 V.
- 6. BCLK Low Time is measured below 0.5 V.

	133	MHz	100	MHz			
T# Parameter	Min	Max	Min	Max	Unit	Figure	Notes
T1: BCLK Period - average	7.5	7.7	10.0	10.2	ns	9	3, 4
T1 _{abs} : BCLK Period - Instantaneous minimum	7.30		9.8		ns		3, 4
T2: BCLK Period Stability		200		200	ps		5
Vcross: Crossing point at 1 V Swing	0.51	0.76	0.51	0.76	V	9

Input Low Voltage	-0.2	0.35	-0.2	0.35	V		
Rising Edge Ring Back	0.35		0.35		V		
Falling Edge Ring Back		-0.35		-0.35	V		

Table 15. System Bus Timing Specifications (Differential Clock)^{1, 2, 6}

1. Unless otherwise noted, all specifications in this table apply to Intel[®] Pentium[®] III processors based on 0.13 micron process at all frequencies.

2. All timings for the AGTL signals are referenced at the rising edge of BCLK and the falling edge of BCLK# at the processor pin. All AGTL signal timings (address bus, data bus, etc.) are referenced at 1.00 V at the processor pins.

3. The internal core clock frequency is derived from the processor system bus clock. The system bus clock to core clock ratio is determined during initialization. Individual processors will only operate at their specified system bus frequency, 133 MHz. Table 16 shows the supported ratios for each processor.

4. Due to the difficulty of accurately measuring clock jitter in a system, it is recommended that a clock driver be used that is designed to meet the period stability specification into a test load of 10 to 20 pF. This should be measured at adjacent crossing points of BCLK and BCLK# which is defined as the rising edge of BCLK and the falling edge of BCLK# at the processor pin. The jitter present must be accounted for as a component of BCLK timing skew between devices.

5. The clock driver's closed loop jitter bandwidth must be set low to allow any PLL-based device to track the jitter created by the clock driver. The –20 dB attenuation point, as measured into a 10 to 20 pF load, should be less than 500 kHz. This specification may be ensured by design characterization and/or measured with a spectrum analyzer. See the appropriate clock synthesizer/driver specification for details.

6. Measurement taken from differential waveform, defined as BCLK - BCLK#.

7. Rise time is measured from -0.35 to +0.35 V and fall time is measured from 0.35 V to -0.35 V.

8. Measured at the socket pin.

Processor	Core Frequency (GHz)	BCLK Frequency (MHz)	Frequency Multiplier
1A	1.00	133	7.5
1.13A	1.13	133	8.5
1.20	1.20	133	9
1.33	1.33	133	10

Table 16. Valid System Bus to Core Frequency Ratios ^{1, 2, 3}

NOTES:

1. Contact your local Intel representative for the latest information on processor frequencies and/or frequency multipliers.

2. While other bus ratios are defined, operation at frequencies other than those listed are not supported by the Intel[®] Pentium[®] III processor based on 0.13 micron process.

3. Individual processors will only operate at their specified system bus frequency; 133 MHz.

Table 17. System Bus Timing Specifications (AGTL Signal Group)^{1, 2, 3}

T# Parameter	Min	Max	Unit	Figure	Notes
T7: AGTL Output Valid Delay	0.40	3.25	ns	11	4
T8: AGTL Input Setup Time	0.95		ns	12	5, 6, 7, 10
T9: AGTL Input Hold Time	1.00		ns	12	8
T10: RESET# Pulse Width	1.00		ms	13	6, 9

NOTES:

- 1. Unless otherwise noted, all specifications in this table apply to Intel [®]Pentium[®] III processors based on 0.13 micron process at all frequencies.
- 2. These specifications are tested during manufacturing.
- 3. All timings for the AGTL signals are referenced to the rising edge of BCLK and the falling edge of BCLK# at the processor pin. All AGTL signal timings (compatibility signals, etc.) are referenced at 0.80 V at the processor pins.
- 4. Valid delay timings for these signals are specified into 50 Ω to 1.25 V, VREF at 0.8 V ±2% and with 56 Ω or 68 Ω on-die R_{TT}. 5. A minimum of 3 clocks must be guaranteed between two active-to-inactive transitions of TRDY#.
- 6. RESET# can be asserted (active) asynchronously, but must be deasserted synchronously.
- 7. Specification is for a minimum 0.40 V swing from VREF 200 mV to VREF + 200 mV. This assumes an edge rate of 0.3 V/ns.
- 8. Specification is for a maximum 0.8 V swing from VTT 0.8 V to VTT. This assumes an edge rate of 3 V/ns.
- 9. This should be measured after Vcc_{CORE} , VT, Vcc_{CMOS} , and BCLK (and BCLK#) are stable. 10.BREQ signals observe a 1.2 ns minimum setup time.

Table 18. System Bus Timing Specifications (CMOS Signal Group) 1, 2, 3, 4

T# Parameter	Min	Max	Unit	Figure	Notes
T14: CMOS Input Pulse Width, except PWRGOOD	2		BCLKs	11	Active and Inactive states
T15: PWRGOOD Inactive Pulse Width	10		BCLKs	15	5

NOTES:

- 1. Unless otherwise noted, all specifications in this table apply to Intel[®] Pentium[®] III processors based on 0.13 micron process at all frequencies
- 2. These specifications are tested during manufacturing.
- 3. These signals may be driven asynchronously.
- 4. All CMOS outputs shall be asserted for at least 2 system bus clocks.
- 5. When driven inactive or after Vcc_{CORE}, VTT, Vcc_{CMOS}, and BCLK and BCLK# are stable.

Table 19. System Bus Timing Specifications (Reset Conditions)¹

T# Parameter	Min	Мах	Unit	Figure	Notes
T16: Reset Configuration Signals (A[14:5]#, BR0#, INIT#) Setup Time	4		BCLKs	13	Before deassertion of RESET#
T17: Reset Configuration Signals (A[14:5]#, BR0#, INIT#) Hold Time	2	20	BCLKs	13	After clock that deasserts RESET#

NOTE:

1. Unless otherwise noted, all specifications in this table apply to all Intel[®] Pentium[®] III processors based on 0.13 micron process frequencies.

Table 20. System Bus Timing Specifications (APIC Clock and APIC I/O)^{1, 2, 3}

T# Parameter	Min	Max	Unit	Figure	Notes
T21: PICCLK Frequency	2.0	33.3	MHz		
T22: PICCLK Period	30.0	500.0	ns	10	
T23: PICCLK High Time	10.5		ns	10	@ > 1.60 V
T24: PICCLK Low Time	10.5		ns	10	@ < 0.40 V
T25: PICCLK Rise Time	0.25	3.0	ns	10	(0.40V - 1.60V)
T26: PICCLK Fall Time	0.25	3.0	ns	10	(1.60 – 0.40 V)
T27: PICD[1:0] Setup Time	8.0		ns	12	4
T28: PICD[1:0] Hold Time	2.5		ns	12	4
T29a: PICD[1:0] Valid Delay (Rising Edge)	1.5	8.7	ns	11	4, 5, 6
T29b: PICD[1:0] Valid Delay (Falling Edge)	1.5	12.0	ns	10	4, 5, 6

NOTES:

1. Unless otherwise noted, all specifications in this table apply to Intel[®] Pentium[®] III processors based on 0.13 micron process at all frequencies.

2. These specifications are tested during manufacturing.

3. All timings for the APIC I/O signals are referenced to the PICCLK rising edge at 0.9 V at the processor pins. All APIC I/O signal timings are referenced at 1.0 V at the processor pins. 4. Referenced to PICCLK rising edge.

- 5. For open drain signals, valid delay is synonymous with float delay.
- 6. Valid delay timings for these signals are specified into 150 Ω load pulled up to 1.5 V.

T# Parameter	Min	Max	Unit	Figure	Notes
T30: TCK Frequency		16.667	MHz		
T31: TCK Period	60.0		ns	10	
T32: TCK High Time	25.0		ns	10	Vcmos_ref + 0.200 V, 10
T33: TCK Low Time	25.0		ns	10	Vcmos_ref - 0.200 V, 10
T34: TCK Rise Time		5.0	ns	10	(Vcmos_ref - 0.200 V) - (Vcmos_ref + 0.200 V), 4, 10
T35: TCK Fall Time		5.0	ns	10	(Vcmos_ref + 0.200 V) - (Vcmos_ref - 0.200 V), 4, 10
T36: TRST# Pulse Width	40.0		ns	17	Asynchronous, 10
T37: TDI, TMS Setup Time	5.0		ns	16	5
T38: TDI, TMS Hold Time	14.0		ns	16	5
T39: TDO Valid Delay	1.0	10.0	ns	16	6, 7
T40: TDO Float Delay		25.0	ns	16	6, 7, 10
T41: All Non-Test Outputs Valid Delay	2.0	25.0	ns	16	6, 8, 9
T42: All Non-Test Inputs Setup Time		25.0	ns	16	6, 8, 9, 10
T43: All Non-Test Inputs Setup Time	5.0		ns	16	5, 8, 9
T44: All Non-Test Inputs Hold Time	13.0		ns	16	5, 8, 9

Table 21. System Bus Timing Specifications (TAP Connection)^{1, 2, 3}

NOTES:

- Unless otherwise noted, all specifications in this table apply to all Intel[®] Pentium[®] III processors based on 0.13 micron process frequencies.
- 2. All timings for the TAP signals are referenced to the TCK rising edge at 1.0 V at the processor pins. All TAP signal timings (TMS, TDI, etc.) are referenced at 1.0 V at the processor pins.
- 3. These specifications are tested during manufacturing, unless otherwise noted.
- 4. 1 ns can be added to the maximum TCK rise and fall times for every 1 MHz below 16.667 MHz.
- 5. Referenced to TCK rising edge.
- 6. Referenced to TCK falling edge.
- 7. Valid delay timing for this signal is specified to 1.5 V.
- 8. Non-Test Outputs and Inputs are the normal output or input signals (besides TCK, TRST#, TDI, TDO, and TMS). These timings correspond to the response of these signals due to TAP operations.
- 9. During Debug Port operation, use the normal specified timings rather than the TAP signal timings.
- 10.Not 100% tested. Specified by design characterization.

Table 22. Platform Power-On Timings²

T# Parameter	Min	Max	Unit	Figure	Notes
T45: Valid Time Before VTT_PWRGD	1.0		ms	14	1
T46: Valid Time Before PWRGOOD	2.0		ms	14	1
T47: RESET# Inactive to Valid Outputs	1		BCLK	14	1
T48: RESET# Inactive to Drive Signals	4		BCLK	14	1

NOTES:

1. All signals, during their invalid states, must be guarded against spurious levels from effecting the platform during processor power-up sequence.

2. Configuration Input signals include: A[14:5], BR0#, INIT#. For timing of these signals, refer to Table 18 and Figure 13.

Notes: For Figure 9 through Figure 19, the following apply:

- 1. Figure 9 through Figure 19 are to be used in conjunction with Table 14 through Table 21.
- All timings for the AGTL signals at the processor pins are referenced to the rising edge of BCLK and the falling edge of BCLK# at the crossing point for differential clock mode and to the rising edge of BCLK at BCLK_{VREF} (1.25 V) for single-ended clock mode. All AGTL signal timings (address bus, data bus, etc.) are referenced at 2/3VTT at the processor pins.
- 3. All timings for the APIC I/O signals at the processor pins are referenced to the PICCLK rising edge at 0.9 V. All APIC I/O signal timings are referenced at 1.0 V at the processor pins.
- 4. All timings for the TAP signals at the processor pins are referenced to the TCK rising edge at 1.0 V. All TAP signal timings (TMS, TDI, etc.) are referenced at 1.0 V at the processor pins.

3.0 Signal Quality Specifications

Signals driven on the processor system bus should meet signal quality specifications to ensure that the components read data properly and to ensure that incoming signals do not affect the long term reliability of the component. Specifications are provided for simulation at the processor pins. Meeting the specifications at the processor pins in Table 23, Table 24, and Table 27 ensures that signal quality effects will not adversely affect processor operation.

3.1 BCLK/BCLK# & PICCLK Signal Quality Specifications and Measurement Guidelines

Table 24 describes the signal quality specifications at the processor pins for the processor system bus clock (BCLK/BCLK#) and APIC clock (PICCLK) signals. References made to BCLK signal quality specifications also applies to BCLK#. Figure 18 describes the signal quality waveform for the system bus clock at the processor pins.

Table 23. BCLK (Single-Ended Clock Mode) Signal Quality Specifications for Simulation at the Processor Pins¹

T# Parameter		Nom	Max	Unit	Figure	Notes
V1: BCLK VIL			0.3	V	18	
V2: BCLK VIH	2.2			V	18	
V3: BCLK Absolute Voltage Range	-0.5		3.1	V	18	
V4: BCLK Rising Edge Ringback	2.0			V	18	2
V5: BCLK Falling Edge Ringback			0.5	V	18	2

Table 24. BCLK/BCLK# (Differential Clock Mode) and PICCLK Signal Quality Specifications for Simulation at the Processor Pins¹

T# Parameter	Min	Nom	Max	Unit	Figure	Notes
V1: BCLK VIL	-0.2		0.35	V	18	
V1: PICCLK VIL			0.40	V	18	
V2: BCLK VIH	0.92		1.45	V	18	
V2 PICCLK VIH	1.60			V	18	
V3: BCLK Absolute Voltage Range	-0.2		1.45	V	18	
V3: PICCLK Absolute Voltage Range	-0.4		2.4	V	18	
V4: BCLK Rising Edge Ringback	0.35			V	18	2
V4: PICCLK Rising Edge Ringback	1.60			V	18	2
V5: BCLK Falling Edge Ringback			-0.35	V	18	2
V5: PICCLK Falling Edge Ringback			0.40	V	18	2

NOTES:

- 1. Unless otherwise noted, all specifications in this table apply to all Intel[®] Pentium[®] III processors based on 0.13 micron process frequencies.
- 2. The rising and falling edge ringback voltage specified is the minimum (rising) or maximum (falling) absolute voltage the BCLK/BCLK# and PICCLK signals can dip back to after passing the VIH (rising) or VIL (falling) voltage limits. This specification is an absolute value.

Figure 18. BCLK/BCLK#, PICCLK Generic Clock Waveform at the Processor Pins

3.2 AGTL Signal Quality Specifications and Measurement Guidelines

Many scenarios have been simulated to generate a set of AGTL layout guidelines that are available in the appropriate platform design guide. Refer to the *Intel[®] Pentium[®] II Processor Developer's Manual* (Order Number 243502) for the AGTL buffer specification.

Table 25 provides the AGTL signal quality specifications for the processor for use in simulating signal quality at the processor pins.

The Pentium III processor based on 0.13 micron process maximum allowable overshoot and undershoot specifications for a given duration of time are detailed in Table 24 through Table 26. Figure 19 shows the AGTL ringback tolerance and Figure 20 shows the overshoot/undershoot waveform.

T# Parameter	Min	Unit	Figure	Notes
α: Overshoot	100	mV	19	4, 8
τ: Minimum Time at High	0.50	ns	19	
ρ: Amplitude of Ringback	±200	mV	19	5, 6, 7, 8
	200	mV	19	8
δ: Duration of Squarewave Ringback	N/A	ns	19	

Table 25. AGTL Signal Groups Ringback Tolerance Specifications at the Processor Pins ^{1, 2, 3}

NOTES:

- 1. Unless otherwise noted, all specifications in this table apply to all Intel[®] Pentium[®] III processors based on 0.13 micron process frequencies.
- 2. Specifications are for the edge rate of 0.3 3 V/ns. See Figure 19 for the generic waveform.
- 3. All values specified by design characterization.
- 4. See Table 24 for maximum allowable overshoot.
- Ringback between VREF + 100 mV and VREF + 200 mV or VREF 300 mV and VREF 100 mVs requires the flight time measurements to be adjusted as described in the Intel AGTL Specifications. Ringback below VREF + 100 mV or above VREF - 100 mV is not supported.
- 6. Intel recommends simulations not exceed a ringback value of VREF ±200 mV to allow margin for other sources of system noise.
- A negative value for ρ indicates that the amplitude of ringback is above VREF. (i.e., φ = -100 mV specifies the signal cannot ringback below VREF + 100 mV).
- 8. ϕ and $\rho:$ are measured relative to VREF. $\alpha:$ is measured relative to VREF + 200 mV.

Figure 19. Low to High AGTL Receiver Ringback Tolerance

3.2.1 Overshoot/Undershoot Guidelines

Overshoot (or undershoot) is the absolute value of the maximum voltage above the nominal high voltage or below Vss. The overshoot guideline limits transitions beyond VCC or Vss due to the fast signal edge rates. The processor can be damaged by repeated overshoot events on 1.25 V or 2.5 V tolerant buffers if the charge is large enough (i.e., if the overshoot is great enough). Determining the impact of an overshoot/undershoot condition requires knowledge of the magnitude, the pulse direction and the activity factor (AF). Permanent damage to the processor is the likely result of excessive overshoot/undershoot. Violating the overshoot/undershoot guideline will also make satisfying the ringback specification difficult.

When performing simulations to determine impact of overshoot and undershoot, ESD diodes must be properly characterized. ESD protection diodes do not act as voltage clamps and will not provide overshoot or undershoot protection. ESD diodes modeled within Intel I/O Buffer models do not clamp undershoot or overshoot and will yield correct simulation results. If other I/O buffer models are being used to characterize the Pentium III processor based on 0.13 micron process performance, care must be taken to ensure that ESD models do not clamp extreme voltage levels. Intel I/O Buffer models also contain I/O capacitance characterization. Therefore, removing the ESD diodes from an I/O Buffer model will impact results and may yield excessive overshoot/undershoot.

3.2.1.1 Overshoot/Undershoot Magnitude

Magnitude describes the maximum potential difference between a signal and its voltage reference level, VSS (overshoot) and VTT (undershoot). While overshoot can be measured relative to VSS using one probe (probe to signal and GND lead to VSS), undershoot must be measured relative to VTT. This could be accomplished by simultaneously measuring the VTT plane while measuring the signal undershoot. Today's oscilloscopes can easily calculate the true undershoot waveform. The true undershoot waveform can also be obtained with the following oscilloscope data file analysis:

Converted Undershoot Waveform = VTT - Signal_measured

intel®

- *Note:* The converted undershoot waveform appears as a positive (overshoot) signal.
- *Note:* Overshoot (rising edge) and undershoot (falling edge) conditions are separate and their impact must be determined independently.

After the true waveform conversion, the undershoot/overshoot specifications shown in Table 26 through Table 29 can be applied to the converted undershoot waveform using the same magnitude and pulse duration specifications used with an overshoot waveform.

Overshoot/undershoot magnitude levels must observe the Absolute Maximum Specifications listed in Table 26 through Table 29. These specifications must not be violated at any time regardless of bus activity or system state. Within these specifications are threshold levels that define different allowed pulse durations. Provided that the magnitude of the overshoot/undershoot is within the Absolute Maximum Specifications (1.78 V AGTL, 2.08 V CMOS), the pulse magnitude, duration and activity factor must all be used to determine if the overshoot/undershoot pulse is within specifications.

3.2.1.2 Overshoot/Undershoot Pulse Duration

Pulse duration describes the total time an overshoot/undershoot event exceeds the overshoot/ undershoot reference voltage (Vos_ref = 1.32 V AGTL, 1.80 V CMOS). The total time could encompass several oscillations above the reference voltage. Multiple overshoot/undershoot pulses within a single overshoot/undershoot event may need to be measured to determine the total pulse duration.

- *Note:* Oscillations below the reference voltage can not be subtracted from the total overshoot/undershoot pulse duration.
- *Note:* Multiple Overshoot/Undershoot events occurring within the same clock cycle must be considered together as one event. Using the worst case Overshoot/Undershoot Magnitude, sum together the individual Pulse Durations to determine the total Overshoot/Undershoot Pulse Duration for that total event.

3.2.1.3 Activity Factor

Activity Factor (AF) describes the frequency of overshoot (or undershoot) occurrence relative to a clock. Since the highest frequency of assertion of an AGTL or a CMOS signal is every other clock, an AF = 1 indicates that the specific overshoot (or undershoot) waveform occurs EVERY OTHER clock cycle. Thus, an AF = 0.01 indicates that the specific overshoot (or undershoot) waveform occurs one time in every 200 clock cycles.

The specifications provided in Table 26 through Table 29 show the Maximum Pulse Duration allowed for a given Overshoot/Undershoot Magnitude at a specific Activity Factor. Each Table entry is independent of all others, meaning that the Pulse Duration reflects the existence of overshoot/undershoot events of that magnitude ONLY. A platform with an overshoot/undershoot that just meets the pulse duration for a specific magnitude where the AF < 1, means that there can be NO other overshoot/undershoot events, even of lesser magnitude (note that if AF = 1, then the event occurs at all times and no other events can occur).

- *Note:* Activity factor for AGTL signals is referenced to system bus clock frequency.
- *Note:* Activity factor for CMOS signals is referenced to PICCLK frequency.

3.2.1.4 Reading Overshoot/Undershoot Specification Tables

The overshoot/undershoot specification for the Pentium III processor based on 0.13 micron process is not a simple single value. Instead, many factors are needed to determine what the over/ undershoot specification is. In addition to the magnitude of the overshoot, the following parameters must also be known: the junction temperature the processor will be operating at, the width of the overshoot (as measured above TBD V) and the Activity Factor (AF). To determine the allowed overshoot for a particular overshoot event, the following must be done:

- 1. Determine the signal group of the particular signal. If the signal is an AGTL signal operating with a 133 MHz system bus, use Table 27 (133 MHz AGTL signal group). If the signal is a CMOS signal, use Table 29 (33 MHz CMOS signal group).
- 2. Determine the maximum case temperature (Tcase) for the range of processors that the system will support (65°C).
- 3. Determine the magnitude of the overshoot (relative to Vss)
- 4. Determine the Activity Factor (how often does this overshoot occur?)
- 5. From the appropriate specification table, read off the maximum pulse duration (in ns) allowed.
- 6. Compare the specified maximum pulse duration to the signal being measured. If the pulse duration measured is less than the pulse duration shown in the table, the signal meets the specifications.

The above procedure is similar for undershoots after the undershoot waveform has been converted to look like an overshoot. Undershoot events must be analyzed separately from Overshoot events as they are mutually exclusive.

The following is an example showing how the maximum pulse duration is determined for a given waveform.

Required Information	Maximum Platform Support	Notes
FSB Signal Group	133 MHz AGTL	
Max Tcase	72 °C	
Overshoot Magnitude	1.78 V	Measured Value
Activity Factor (AF)	0.1	Measured overshoot occurs on average every 20 clocks

Table 26. Example Platform Information

Given the above parameters and using Table 27 ($65^{\circ}C/AF = 0.1$ column), the maximum allowed pulse duration is 7.5 ns. Since the measure pulse duration is 7.5 ns, this particular overshoot event passes the overshoot specifications, although this doesn't guarantee that the combined overshoot/ undershoot events meet the specifications.

3.2.1.5 Determining if a System Meets the Overshoot/Undershoot Specifications

The overshoot/undershoot specifications listed in the following tables specify the allowable overshoot/undershoot for a single overshoot/undershoot event. However, most systems will have multiple overshoot and/or undershoot events that each have their own set of parameters (duration, AF and magnitude). While each overshoot on its own may meet the overshoot specification, when you add the total impact of all overshoot events, the system may fail. A guideline to ensure a system passes the overshoot and undershoot specifications is shown below. It is important to meet these guidelines; otherwise, contact your Intel field representative.

- Insure no AGTL signal ever exceeds 1.78 V and no CMOS signal ever exceeds 2.08 V. OR
- If only one overshoot/undershoot event magnitude occurs, ensure it meets the over/undershoot specifications in the following tables OR
- 3. If multiple overshoots and/or multiple undershoots occur, measure the worst case pulse duration for each magnitude and compare the results against the AF = 1 specifications. If all of these worst case overshoot or undershoot events meet the specifications (measured time < specifications) in the table (where AF=1), then the system passes.

The following notes apply to Table 26 through Table 29.

NOTES:

- 1. Overshoot/Undershoot Magnitude = 1.78 V (AGTL), 2.08 V (CMOS) is an absolute value and should never be exceeded
- 2. Overshoot is measured relative to Vss.
- 3. Undershoot is measured relative to VTT
- 4. Overshoot/Undershoot Pulse Duration is measured relative to 1.32 V for AGTL and 1.80 V for CMOS.
- 5. Rinbacks below VTT can not be subtracted from Overshoots/Undershoots
- 6. Lesser Undershoot does not allocate longer or larger Overshoot
- 7. OEMs are encouraged to follow Intel provided layout guidelines. Consult the layout guidelines provided in the specific platform design guide.
- 8. All values specified by design characterization

Table 27. 133 MHz AGTL Signal Group Overshoot/Undershoot Tolerance 1, 2, 3

Overshoot/ Undershoot Magnitude	C	kimum Pu Ouration a se = 60 °C	at	Maximum Pulse Duration at Tcase = 69 °C (ns)		Maximum Pulse Duration at Tcase = 71 °C (ns)			Maximum Pulse Duration at Tcase = 72 °C (ns)			
(V)	AF = 0.01	AF = 0.1	AF = 1	AF = 0.01	AF = 0.1	AF = 1	AF = 0.01	AF = 0.1	AF = 1	AF = 0.01	AF = 0.1	AF = 1
1.78	15	1.5	0.153	8.7	0.87	0.087	6	0.6	0.06	6	0.6	0.06
1.73	15	3.1	0.31	15	2.0	0.20	13	1.3	0.13	12	1.2	0.12
1.68	15	6.8	0.68	15	4.6	0.46	20	2.8	0.28	20	2.7	0.27
1.63	15	14	1.42	15	10	1.0	20	6	0.6	20	5	0.57

1.48	15	15	13.2	15	15	15	20	20	5.45	20	20	5.10

NOTES:

1. Measurements taken at the processor socket pins on the solder-side of the motherboard.

2. Overshoot/Undershoot Magnitude = 1.78 V is an absolute value and should never be exceeded.

3. BCLK Period = 7.5 ns.

Figure 20. Maximum Acceptable AGTL Overshoot/Undershoot Waveform

3.3 Non-AGTL Signal Quality Specifications and Measurement Guidelines

There are three signal quality parameters defined for non-AGTL signals: overshoot/undershoot, ringback, and settling limit. All three signal quality parameters are shown in Figure 21 for the non-AGTL signal group.

Figure 21. Non-AGTL Overshoot/Undershoot, Settling Limit, and Ringback¹

NOTE:

1. V_{HI} = 1.80 V for all non-AGTL signals except for BCLK, PICCLK, and PWRGOOD. V_{HI} =2.0 V for PICCLK, and V_{HI} =1.8 V for PWRGOOD. BCLK and PICCLK signal quality is detailed in Section 3.1.

3.3.1 Overshoot/Undershoot Guidelines

Overshoot (or undershoot) is the absolute value of the maximum voltage above the nominal high voltage or below VSs. The overshoot guideline limits transitions beyond VCC or VSs due to the fast signal edge rates (see Figure 21 for non-AGTL signals). The processor can be damaged by repeated overshoot events on 1.25 V or 1.8 V tolerant buffers if the charge is large enough (i.e., if the overshoot is great enough). Permanent damage to the processor is the likely result of excessive overshoot/undershoot. Violating the overshoot/undershoot guideline *is 0.3 V* and assumes the absence of diodes on the input. These guidelines should be verified in simulations *without the on-chip ESD protection diodes present* because the diodes will begin clamping the 1.25 V and 2.5 V tolerant signals beginning at approximately 0.7 V above the appropriate supply and 0.7 V below Vss. If signals are not reaching the clamping voltage, this will not be an issue. A system should not rely on the diodes for overshoot/undershoot protection as this will negatively affect the life of the components and make meeting the ringback specification very difficult.

Table 28. 33 MHz CMOS Signal Group Overshoot/Undershoot Tolerance

		m Pulse D Ise = 69 °C		Maximum Pulse Duration at Tcase = 71 °C (ns)			Maximum Pulse Duration at Tcase = 72 °C (ns)		
Magnitude (V)	AF = 0.01	AF = 0.1	AF = 1	AF = 0.01	AF = 0.1	AF = 1	AF = 0.01	AF = 0.1	AF = 1
2.38	35	3.5	0.35	19	1.9	0.19	17	1.7	0.17
2.33	60	8.0	0.8	40	4	0.40	36	3.6	0.36
2.28	60	18	1.8	60	8	0.80	60	7	0.77
2.23	60	41	4.1	60	18	1.80	60	16	1.60
2.18	60	60	9.0	60	37	3.75	60	34	3.42
2.13	60	60	21	60	60	8	60	60	7
2.08	60	60	60	60	60	16	60	60	14

NOTES:The undershoot guideline limits transitions exactly as described for the ATGL signals. See Figure 20.

3.3.2 Ringback Specification

Ringback refers to the amount of reflection seen after a signal has switched. The ringback specification is the voltage that the signal rings back to after achieving its maximum absolute value. See Figure 21 for an illustration of ringback. Excessive ringback can cause false signal detection or extend the propagation delay. The ringback specification applies to the input pin of each receiving agent. Violations of the signal ringback specification are not allowed under any circumstances for non-AGTL signals.

Ringback can be simulated with or without the input protection diodes that can be added to the input buffer model. However, signals that reach the clamping voltage should be evaluated further. See Table 29 for the signal ringback specifications for non-AGTL signals for simulations at the processor pins.

Table 29. Signal Ringback Specifications for Non-AGTL Signal Simulation at the Processor Pins ¹

Input Signal Group	Transition	Maximum Ringback (with Input Diodes Present)	Unit	Figure
Non-AGTL Signals ²	$0 \rightarrow 1$	Vcmos_ref + 0.200	V	21
Non-AGTL Signals ²	$1 \rightarrow 0$	Vcmos_ref – 0.300	V	21
PWRGOOD	$0 \rightarrow 1$	1.44	V	21

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all Intel[®] Pentium[®] III processor based on 0.13 micron process frequencies.

2. Non-AGTL signals except PWRGOOD.

3.3.3 Settling Limit Guideline

Settling limit defines the maximum amount of ringing at the receiving pin that a signal must reach before its next transition. The amount allowed is 10% of the total signal swing (V_{HI} - V_{LO}) above and below its final value. A signal should be within the settling limits of its final value, when either in its high state or low state, before it transitions again.

Signals that are not within their settling limit before transitioning are at risk of unwanted oscillations which could jeopardize signal integrity. Simulations to verify settling limit may be done either with or without the input protection diodes present. Violation of the settling limit guideline is acceptable if simulations of 5 to 10 successive transitions do not show the amplitude of the ringing increasing in the subsequent transitions.

4.0 Thermal Specifications and Design Considerations

This chapter provides needed data for designing a thermal solution. However, for the correct thermal measuring processes, refer to the *Intel[®] Pentium[®] III Processor in the FC-PGA2 Package Thermal Design Guidelines* document. The Pentium III processor based on 0.13 micron process uses flip chip pin grid array packaging technology with a Integrated Heat Spreader and has a **case** temperature (T_{case}) specified.

4.1 Thermal Specifications

Table 30 provides the thermal design power dissipation and maximum temperatures for the Pentium III processor based on 0.13 micron process. Systems should design for the highest possible processor power, even if a processor with a lower thermal dissipation is planned. A thermal solution should be designed to ensure the case temperature never exceeds these specifications.

Table 30. Intel[®] Pentium[®] III Processor Based on 0.13 micron Process Thermal Design Power ¹

Processor	Processor Core Frequency (GHz)	L2 Cache Size (KBs)	Processor Power ² (W)	Maximum T _{CASE} (°C)
1A	1.00	256	27.6	69
1.13A	1.13	256	29.1	69
1.20	1.20	256	29.9	69
1.33	1.33	256	33.9	71

NOTES:

1. These values are specified at nominal $\ensuremath{\mathsf{Vcc}_{\mathsf{CORE}}}$ for the processor pins.

2. Processor power includes the power dissipated by the processor core, the L2 cache, and the AGTL bus termination. The maximum power for each of these components does not occur simultaneously.

3. Processor core power includes only the power dissipated by the core die.

4.1.1 THERMTRIP# Requirement

In the event the processor drives the THERMTRIP# signal active during valid operation, both the VCC and VTT supplies to the processor must be turned off to prevent thermal runaway of the processor. Valid operation refers to the operating conditions where the THERMTRIP# signal is guaranteed valid. The time required from THERMTRIP# asserted to VCC rail at 1/2 nominal is 5 sec and THERMTRIP# asserted to VTT rail at 1/2 nominal is 5 sec.

Table 31. THERMTRIP# Time Requirement

Power Rail	Power Target	Time Required For Power Drop
Vcc	1/2 Nominal Vcc	5 seconds
VTT	1/2 Nominal VTT	5 seconds

NOTE: Once Vcc and VTT supplies are turned off the THERMTRIP# signal will be deactivated. System logic should ensure no "unsafe" power cycling occurs due to this deassertion.

4.1.2 **Thermal Diode**

The Pentium III processor based on 0.13 micron process incorporates an on-die diode that may be used to monitor the die temperature (junction temperature). A thermal sensor located on the motherboard, or a stand-alone measurement kit, may monitor the die temperature of the processor for thermal management or instrumentation purposes. Table 32 and Table 33 provide the diode parameter and interface specifications.

The Pentium III processor based on 0.13 micron process uses an Integrated Heat Spreader (IHS) and has a case temperature requirement. See the Intel[®] Pentium[®] III Processor in the FC-PGA2 Package Thermal Design Guidelines document for details on measuring the case temperature. The thermal diode should be used for system thermal management and not determining specification compliance.

Table 32. Thermal Diode Parameters¹

Symbol	Parameter	Min	Тур	Max	Unit	Notes
I _{fw}	Forward Bias Current	5	N/A	150	μΑ	1
n	Diode Ideality Factor	1.001452	1.007152	1.012852		2, 4, 5
I _{fw}	Forward Bias Current	5	N/A	300	μΑ	1
n	Diode Ideality Factor	1.000807	1.009528	1.018249		3, 4, 5

NOTES:

1. Intel does not support or recommend operation of the thermal diode under reverse bias.

- 2. Characterized at 75° C with a forward bias current of 5 150 μ A. 3. Characterized at 75° C with a forward bias current of 5 300 μ A.
- 4. The ideality factor, n, represents the deviation from ideal diode behavior as exemplified by the diode equation:

 $I_{fw} = Is(e^{(Vd^*q)/(nkT))} - 1)$, where Is = saturation current, q = electronic charge, Vd = voltage across the diode, k = Boltzmann Constant, and T = absolute temperature (Kelvin).

5. Not 100% tested. Specified by design characterization.

Table 33. Thermal Diode Interface

Pin Name	PGA370 Socket pin #	Pin Description
THERMDP	AL31	diode anode (p_junction)
THERMDN	AL29	diode cathode (n_junction)

4.2 **Thermal Metrology**

The thermal metrology for the Pentium III processor based on 0.13 micron process in the FC-PGA2 package should be followed to evaluate the thermal performance of proposed cooling solutions. The thermal metrology is contained in the Intel[®] Pentium[®] III Processor in the FC-PGA2 Package Thermal Design Guidelines document.

5.0 Mechanical Specifications

The Pentium III processor based on 0.13 micron process uses a FC-PGA2 package technology. Mechanical specifications for the processor are given in this section. See Section 1.1.1 for a complete terminology listing.

The processor utilizes a PGA370 socket for installation into the motherboard. Details on the socket are available in the *370-Pin Socket (PGA370) Design Guidelines*.

- *Note:* For Figure 22, the following apply:
 - 1. Unless otherwise specified, the following drawings are dimensioned in inches.
 - 2. All dimensions provided with tolerances are guaranteed to be met for all normal production product.
 - 3. Figures and drawings labeled as "Reference Dimensions" are provided for informational purposes only. Reference dimensions are extracted from the mechanical design database and are nominal dimensions with no tolerance information applied. Reference dimensions are NOT checked as part of the processor manufacturing. Unless noted as such, dimensions in parentheses without tolerances are reference dimensions.
 - 4. Drawings are not to scale.

5.1 FC-PGA2 Mechanical Specifications

Figure 22 is provided to aid in the design of heatsink and clip solutions as well as demonstrate where pin-side capacitors will be located on the processor. Table 34 includes the measurements for these dimensions in both inches and millimeters.

Figure 22. Package Dimensions

0		Millimeters			Inches	
Symbol	Minimum	Maximum	Notes	Minimum	Maximum	Notes
A1	2.266	2.690		0.089	0.106

Table 34. Intel[®] Pentium[®] III Processor Based on 0.13 micron Process Package Dimensions

NOTE: Capacitors will be placed on the pin-side of the FC-PGA2 package in the area defined by G1, G2, and G3. This area is a keepout zone for motherboard designers.

For Table 35, the following apply:

- 1. It is not recommended to use any portion of the processor substrate as a mechanical reference or load bearing surface for thermal solutions.
- 2. Parameters assume uniformly applied loads.

Table 35. Processor Case Loading Parameters

Parameter	Dynamic (max) ¹	Static (max) ^{2,3}	Unit
IHS Surface	200	100	lbf
IHS Edge	125	N/A	lbf
IHS Corner	75	N/A	ibf

NOTES:

- 1. This specification applies to a uniform and a non-uniform load.
- 2. This is the maximum static force that can be applied by the heatsink and clip to maintain the heatsink and processor interface.
- 3. See socket manufacturer's force loading specification also to ensure compliance. Maximum static loading listed here does not account for the maximum reaction forces on the socket tabs or pins.

5.2 Recommended Mechanical Keep-Out Zones

Figure 23. Volumetric Keep-Out

Figure 24. Component Keep-Out

5.3 Processor Markings

Figure 25 shows the processor top-side markings; the markings are provided to aid in the identification of a Pentium III processor based on 0.13 micron process. Table 34 lists the measurements for the package dimensions.

Figure 25. Top Side Processor Markings

5.4 Processor Signal Listing

Table 36 and Table 37 provide the processor pin definitions. The signal locations on the PGA370 socket are to be used for signal routing, simulation, and component placement on the baseboard. Figure 26 provides a pin-side view of the Pentium III processor based on 0.13 micron process pinout.

Figure 26. Intel [®] Pentium [®] III Processor Based on 0.13 micron P	Process Pinout

6.0 Boxed Processor Specifications

The Pentium III processor based on 0.13 micron process for the PGA370 socket may also be offered as an Intel boxed processor. Intel boxed processors are intended for system integrators who build systems from motherboards and standard components. The boxed Pentium III processor based on 0.13 micron process will be supplied with an unattached fan heatsink.

This section documents motherboard and system requirements for the fan heatsink that will be supplied with the boxed Pentium III processor based on 0.13 micron process. This section is particularly important for OEMs that manufacture motherboards for system integrators. Unless otherwise noted, all figures in this section are dimensioned in inches. Figure 27 shows a mechanical representation of the boxed Intel Pentium III processor based on 0.13 micron process in the Flip Chip Pin Grid Array 2 (FC-PGA2) package.

- *Note:* Drawings in this section reflect only the specifications on the Intel Boxed processor product. These dimensions should not be used as a generic keep-out zone for all heatsinks. It is the system designer's responsibility to consider their proprietary solution when designing to the required keep-out zone on their system platform and chassis. Refer to the *Intel*[®] *Pentium*[®] *III processor Thermal/Mechanical Functional Specification* for further guidance. Contact your local Intel Sales Representative for this document.
- Figure 27. Conceptual Boxed Intel[®] Pentium[®] III Processor Based on 0.13 micron Process for the PGA370 Socket

6.1 Mechanical Specifications

6.1.1 Mechanical Specifications for the FC-PGA2 Package

This section documents the mechanical specifications of the boxed Pentium III processor based on 0.13 micron process fan heatsink in the FC-PGA2 Package. The boxed processor in the FC-PGA2 Package ships with an un-attached fan heatsink. Figure 27 shows a mechanical representation of the boxed Pentium III processor based on 0.13 micron process for the PGA370 socket in the Flip Chip Pin Grid Array 2 (FC-PGA2) package.

The boxed processor fan heatsink is also asymmetrical in that the mechanical step feature, Figure 30, must sit over the socket's cam. The step allows the heatsink to securely interface with the processor in order to meet the processor's thermal requirements.

The dimensions for the boxed processor with the integrated fan heatsink are shown in Figure 29. All dimensions are in inches.

The Pentium III processor based on 0.13 micron process uses a new technology termed FC-PGA2. The FC-PGA2 package leverages the previous FC-PGA package technology used on Intel Pentium III processors based on 0.18 micron technology (CPUID=068xh). The FC-PGA2 package adds an Integrated Heat Spreader (IHS) to improve heat conduction from the processor die. This new solution prevent the need for exotic thermal solutions in the higher power density processors. See Section 5.0 of this document for the mechanical specifications of the PGA370 socket.

Section 5.2 of this document also shows the recommended mechanical keepout zones for the boxed processor fan heatsink assembly. Figure 23 and Figure 24 show the REQUIRED keepout dimensions for the boxed processor thermal solution. The cooling fin orientation on the heatsink relative to the PGA370 socket is subject to change. Contact your local Intel Sales Representative for documentation specific to the boxed fan heatsink orientation relative to the PGA370 socket.

Figure 28 shows the changes to the package mechanicals between the FC-PGA and FC-PGA2 designs. Note that the boxed fan heatsinks and associated clips are not compatible with earlier boxed Intel Pentium III processors based on 0.18 micron technology (CPUID=068xh) fan heatsinks.

Figure 28. Comparison between FC-PGA and FC-PGA2 package

Figure 29. Side View of Space Requirements for the Boxed Processor

 Table 38. Boxed Processor Fan Heatsink Spatial Dimensions

Dimensions (Inches)	Min	Тур	Max	Units
Fan Heatsink Length			3.14	Inches
Fan Heatsink Height			1.81	Inches
Fan Heatsink Width			2.6	Inches
Fan Heatsink height above motherboard	0.29	0.30	0.33	Inches
Air Keepout Zones from end of Fan Heatsink	0.20			Inches

Figure 30. Dimensions of Mechanical Step Feature in Heatsink Base

6.1.2 Boxed Processor Heatsink Weight

The boxed processor thermal cooling solution will not weigh more than 180 grams.

6.2 Thermal Specifications

This section describes the cooling requirements of the thermal cooling solution utilized by the boxed processor.

6.2.1 Boxed Processor Cooling Requirements

The boxed processor is directly cooled with a fan heatsink. However, meeting the processor's temperature specification is also a function of the thermal design of the entire system and ultimately the responsibility of the system integrator. The processor temperature specification is found in Section 4.1 of this document. The boxed processor fan heatsink is able to keep the processor temperature within the specifications (see Table 30 in Section 4.1) in chassis that provide good thermal management.

For the boxed processor fan heatsink to operate properly, it is critical that the airflow provided to the fan heatsink is unimpeded. Airflow of the fan heatsink is into the center and out of the sides of the fan heatsink. Airspace is required around the fan to ensure that the airflow through the fan heatsink is not blocked. Blocking the airflow to the fan heatsink reduces the cooling efficiency and decreases fan life. Figure 31 illustrate an acceptable airspace clearance for the fan heatsink. It is also recommended that the air temperature entering the fan be kept below 45 °C. Again, meeting the processor's temperature specification is the responsibility of the system integrator. The processor temperature specification is found in Section 4.1 of this document.

Figure 31. Thermal Airspace Requirement for all Boxed Intel[®] Pentium[®] III Processor Based on 0.13 micron Process Fan Heatsinks in the PGA370 Socket

6.2.2 Boxed Processor Thermal Cooling Solution Clip

The boxed processor thermal solution requires installation by a system integrator to secure the thermal cooling solution to the processor after it is installed in the 370-pin socket ZIF socket. Motherboards designed for use by system integrators should take care to consider the implications of clip installation and potential scraping of the motherboard PCB underneath the 370-pin socket attach tabs. Motherboard components should not be placed too close to the 370-pin socket attach tabs in a way that interferes with the installation of the boxed processor thermal cooling solution Figure 24 show the REQUIRED keepout dimensions for the boxed processor thermal solution.

6.3 Electrical Requirements for the Boxed Intel[®] Pentium[®] III Processor Based on 0.13 micron Process

6.3.1 Electrical Requirements

The boxed processor's fan heatsink requires a +12 V power supply. A fan power cable is attached to the fan and will draw power from a power header on the motherboard. The power cable connector and pinout are shown in Figure 32. Motherboards must provide a matched power header to support the boxed processor. Table 38 contains specifications for the input and output signals at the fan heatsink connector. The fan heatsink outputs a SENSE signal (an open-collector output) that pulses at a rate of two pulses per fan revolution. A motherboard pull-up resistor provides V_{OH} to match the motherboard-mounted fan speed monitor requirements, if applicable. Use of the SENSE signal is optional. If the SENSE signal is not used, pin 3 of the connector should be tied to GND.

The power header on the baseboard must be positioned to allow the fan heatsink power cable to reach it. The power header identification and location should be documented in the motherboard documentation or on the motherboard. Figure 33 shows the recommended location of the fan power connector relative to the PGA370 socket. The motherboard power header should be positioned within 4.00 inches (lateral) of the fan power connector for the FC-PGA2 package.

Figure 32. Boxed Processor Fan Heatsink Power Cable Connector Description

Table 39. Fan Heatsink Power and Signal Specifications

Description	Min	Тур	Мах
+12 V: 12 volt fan power supply	10.8 V	12 V	13.2 V
IC: Fan current draw			100 mA
SENSE: SENSE frequency (motherboard should pull this pin up to appropriate Vcc with resistor)		2 pulses per fan revolution

7.0 Processor Signal Description

This section provides an alphabetical listing of all the Pentium III processor based on 0.13 micron process signals. The tables at the end of this section summarize the signals by direction: output, input, and I/O.

7.1 Alphabetical Signals Reference

 Table 40. Signal Description (Sheet 1 of 8)

Name	Туре	Description
A20M#	I	If the A20M# (Address-20 Mask) input signal is asserted, the processor masks physical address bit 20 (A20#) before looking up a line in any internal cache and before driving a read/write transaction on the bus. Asserting A20M# emulates the 8086 processor's address wrap-around at the 1 MB boundary. Assertion of A20M# is only supported in real mode. A20M# is an asynchronous signal. However, to ensure recognition of this signal following an I/O write instruction, it must be valid along with the TRDY# assertion of
		the corresponding I/O Write bus transaction. The A[35:3]# (Address) signals define a 2 ³⁶ -byte physical memory address space.
A[35:3]#	I/O	When ADS# is active, these pins transmit the address of a transaction; when ADS# is inactive, these pins transmit transaction type information. These signals must connect the appropriate pins of all agents on the processor system bus. The A[35:24]# signals are parity-protected by the AP1# parity signal, and the A[23:3]# signals are parity-protected by the AP0# parity signal.
		On the active-to-inactive transition of RESET#, the processors sample the A[35:3]# pins to determine their power-on configuration. See the Intel [®] <i>Pentium[®] II Processor Developer's Manual</i> for details.
ADS#	I/O	The ADS# (Address Strobe) signal is asserted to indicate the validity of the transaction address on the A[35:3]# pins. All bus agents observe the ADS# activation to begin parity checking, protocol checking, address decode, internal snoop, or deferred reply ID match operations associated with the new transaction. This signal must connect the appropriate pins on all processor system bus agents.
AERR#	I/O	The AERR# (Address Parity Error) signal is observed and driven by all processor system bus agents, and if used, must connect the appropriate pins on all processor system bus agents. AERR# observation is optionally enabled during power-on configuration; if enabled, a valid assertion of AERR# aborts the current transaction. If AERR# observation is disabled during power-on configuration, a central agent may handle an assertion of AERR# as appropriate to the error handling architecture of the system.
AP[1:0]#	I/O	The AP[1:0]# (Address Parity) signals are driven by the request initiator along with ADS#, A[35:3]#, REQ[4:0]#, and RP#. AP1# covers A[35:24]#, and AP0# covers A[23:3]#. A correct parity signal is high if an even number of covered signals are low and low if an odd number of covered signals are low. This allows parity to be high when all the covered signals are high. AP[1:0]# should connect the appropriate pins of all processor system bus agents.
BCLK/BCLK#	I	The BCLK (Bus Clock) and BCLK# (for differential clock) signals determines the bus frequency. All processor system bus agents must receive this signal to drive their outputs and latch their inputs on the rising edge of BCLK. For differential clocking, all processor system bus agents must receive this signal to drive their outputs and latch their inputs on the BCLK and BCLK# crossing point. All external timing parameters are specified with respect to the BCLK signal.

Table 40.	Signal	Description	(Sheet 2 of 8)
-----------	--------	-------------	----------------

Name	Туре	Description
		The BERR# (Bus Error) signal is asserted to indicate an unrecoverable error without a bus protocol violation. It may be driven by all processor system bus agents, and must connect the appropriate pins of all such agents, if used. However, Pentium III processors based on 0.13 micron process do not observe assertions of the BERR# signal.
BERR#	I/O	BERR# assertion conditions are configurable at a system level. Assertion options are defined by the following options:
		Enabled or disabled.
		 Asserted optionally for internal errors along with IERR#.
		 Asserted optionally by the request initiator of a bus transaction after it observes an error.
		 Asserted by any bus agent when it observes an error in a bus transaction.
		The BINIT# (Bus Initialization) signal may be observed and driven by all processor system bus agents, and if used must connect the appropriate pins of all such agents. If the BINIT# driver is enabled during power on configuration, BINIT# is asserted to signal any bus condition that prevents reliable future information.
BINIT#	I/O	If BINIT# observation is enabled during power-on configuration, and BINIT# is sampled asserted, all bus state machines are reset and any data which was in transit is lost. All agents reset their rotating ID for bus arbitration to the state after Reset, and internal count information is lost. The L1 and L2 caches are not affected.
		If BINIT# observation is disabled during power-on configuration, a central agent may handle an assertion of BINIT# as appropriate to the error handling architecture of the system.
		The BNR# (Block Next Request) signal is used to assert a bus stall by any bus agent who is unable to accept new bus transactions. During a bus stall, the current bus owner cannot issue any new transactions.
BNR#	I/O	Since multiple agents might need to request a bus stall at the same time, BNR# is a wire-OR signal which must connect the appropriate pins of all processor system bus agents. In order to avoid wire-OR glitches associated with simultaneous edge transitions driven by multiple drivers, BNR# is activated on specific clock edges and sampled on specific clock edges.
BP[3:2]#	I/O	The BP[3:2]# (Breakpoint) signals are outputs from the processor that indicate the status of breakpoints.
BPM[1:0]#	I/O	The BPM[1:0]# (Breakpoint Monitor) signals are breakpoint and performance monitor signals. They are outputs from the processor which indicate the status of breakpoints and programmable counters used for monitoring processor performance.
BPRI#	I	The BPRI# (Bus Priority Request) signal is used to arbitrate for ownership of the processor system bus. It must connect the appropriate pins of all processor system bus agents. Observing BPRI# active (as asserted by the priority agent) causes all other agents to stop issuing new requests, unless such requests are part of an ongoing locked operation. The priority agent keeps BPRI# asserted until all of its requests are completed, then releases the bus by deasserting BPRI#.
BR0#	I/O	The BR0# (Bus Request) pins drive the BREQ[0]# signal in the system. During power-up configuration, the central agent asserts the BR0# bus signal in the system to assign the symmetric agent ID to the processor. The processor samples its BR0# pin on the active-to-inactive transition of the RESET# to obtain its symmetric agent ID. The processor asserts the BR0# pin to request the system bus. BR0# must be connected to a 10–56 Ω resistor to Vss. Refer to the platform design guide for implementation detail and resistor tolerance.

Table 40. Signal Description (Sheet 3 of 8)

Name	Туре		Dese	cription	
BSEL[1:0]	0	The BSEL signals are CMOS signals which are used to select the system bus frequency. A BSEL[1:0] = '11' selects a 133 MHz system bus frequency. The frequency is determined by the processor(s), chipset, and frequency synthesizer capabilities. All system bus agents must operate at the same frequency. The Pentium III processor based on 0.13 micron process operates at 133 MHz system bus frequency. These signals must be pulled up to 3.3 V power rail with 330–1 k Ω resistors and provided as a frequency selection signal to the clock driver/synthesizer and chipset.			
		Refer to the platfo	rm design guide for in	F input is a filtered 1.25 V supply voltage for	
CLKREF	I	the processor PLL	. A voltage divider an	d decoupling solution is provided by the mplementation details.	
		When the process BCLK#.	or operates in differer	tial clock mode, this signal becomes

			Occupation Truth Table		
CPUPRES#	0	Signal	Value	Status	
		CPUPRES# VID[25mV,3:0]	0 Anything other than '11111'	Processor core installed in the PGA370 socket.	
		CPUPRES# VID[25mV,3:0]	1 Any value	PGA370 socket not occupied.	
D[63:0]#	I/O	The D[63:0]# (Data) signals are the data signals. These signals provide a 64-bit data path between the processor system bus agents, and must connect the appropriate pins on all such agents. The data driver asserts DRDY# to indicate a valid data transfer.			
DBSY#	I/O	data on the proces bus is released aff	The DBSY# (Data Bus Busy) signal is asserted by the agent responsible for driving data on the processor system bus to indicate that the data bus is in use. The data bus is released after DBSY# is deasserted. This signal must connect the appropriate pins on all processor system bus agents.		
DEFER#	I	guaranteed in-ord of the addressed r	The DEFER# signal is asserted by an agent to indicate that a transaction cannot be guaranteed in-order completion. Assertion of DEFER# is normally the responsibility of the addressed memory or I/O agent. This signal must connect the appropriate pins of all processor system bus agents.		
DEP[7:0]#	I/O	The DEP[7:0]# (Data Bus ECC Protection) signals provide optional ECC protection for the data bus. They are driven by the agent responsible for driving D[63:0]#, and must connect the appropriate pins of all processor system bus agents that use them. The DEP[7:0]# signals are enabled or disabled for ECC protection during power on configuration.			
DETECT	0	A tri-state (high-impedance) output. Can be used for platforms that need to differentiate Pentium III processors based on 0.13 micron process that support VTT =1.25 V only, from Pentium III processors (AF36=VSS) that support VTT =1.50 V only. The output on this signal is stable when VTT is stable. Refer to the appropriate platform design guide for implementation details.			
DRDY#	I/O	transfer, indicating may be deasserte	The DRDY# (Data Ready) signal is asserted by the data driver on each data transfer, indicating valid data on the data bus. In a multi-cycle data transfer, DRDY# may be deasserted to insert idle clocks. This signal must connect the appropriate pins of all processor system bus agents.		

Table 40.	Signal	Description	(Sheet 4 of 8)
-----------	--------	-------------	----------------

Name	Туре	Description
DYN_OE	I	The DYN_OE allows the BSEL and VID signals to be driven out from the processor. When this signal is low (a condition that will occur if the Pentium III processor based on 0.13 micron process is installed in a non-supported platform), the VID and BSEL signals will be tri-stated and the platform pull-up resistors will set the VID and BSEL to all 1s which is a safe setting. This signal must be connected to a 1 k Ω resistor to VTT. Refer to the platform design guide for implementation detail and resistor tolerance.
FERR#	ο	The FERR# (Floating-point Error) signal is asserted when the processor detects an unmasked floating-point error. FERR# is similar to the ERROR# signal on the Intel 387 coprocessor, and is included for compatibility with systems using MS-DOS*-type floating-point error reporting.
		When the FLUSH# input signal is asserted, processors write back all data in the Modified state from their internal caches and invalidate all internal cache lines. At the completion of this operation, the processor issues a Flush Acknowledge transaction. The processor does not cache any new data while the FLUSH# signal remains asserted. FLUSH# is an asynchronous signal. However, to ensure recognition of this signal
FLUSH#	I	following an I/O write instruction, it must be valid along with the TRDY# assertion of the corresponding I/O Write bus transaction.
		On the active-to-inactive transition of RESET#, each processor samples FLUSH# to determine its power-on configuration. See the <i>P6 Family of Processors Hardware Developer's Manual</i> for details.
		This signal must be connected to a 150 Ω resistor to VCC _{CMOS1.5} . Refer to the platform design guide for implementation detail and resistor tolerance.
HIT# HITM#	I/O I/O	The HIT# (Snoop Hit) and HITM# (Hit Modified) signals convey transaction snoop operation results, and must connect the appropriate pins of all processor system bus agents. Any such agent may assert both HIT# and HITM# together to indicate that it requires a snoop stall, which can be continued by reasserting HIT# and HITM# together.
IERR#	0	The IERR# (Internal Error) signal is asserted by a processor as the result of an internal error. Assertion of IERR# is usually accompanied by a SHUTDOWN transaction on the processor system bus. This transaction may optionally be converted to an external error signal (e.g., NMI) by system core logic. The processor will keep IERR# asserted until the assertion of RESET#, BINIT#, or INIT#.
IGNNE#	I	The IGNNE# (Ignore Numeric Error) signal is asserted to force the processor to ignore a numeric error and continue to execute noncontrol floating-point instructions. If IGNNE# is deasserted, the processor generates an exception on a noncontrol floating-point instruction if a previous floating-point instruction caused an error. IGNNE# has no effect when the NE bit in control register 0 is set.
		IGNNE# is an asynchronous signal. However, to ensure recognition of this signal following an I/O write instruction, it must be valid along with the TRDY# assertion of the corresponding I/O Write bus transaction.
INIT#	I	The INIT# (Initialization) signal, when asserted, resets integer registers inside all processors without affecting their internal (L1 or L2) caches or floating-point registers. Each processor then begins execution at the power-on Reset vector configured during power-on configuration. The processor continues to handle snoop requests during INIT# assertion. INIT# is an asynchronous signal and must connect the appropriate pins of all processor system bus agents.
		If INIT# is sampled active on the active to inactive transition of RESET#, then the processor executes its Built-in Self-Test (BIST).
KEY	I	Can be used to prevent legacy processors from booting in incompatible platforms. Legacy processors use this pin as a RESET and should be tied to ground for a Pentium III processor based on 0.13 micron process only platform but for flexible platform implementations this pin should be a No Connect. Refer to the appropriate platform design guide for implementation details.

Table 40. Signal Description (Sheet 5 of 8)

Name	Туре	Description
LINT[1:0]	I	The LINT[1:0] (Local APIC Interrupt) signals must connect the appropriate pins of all APIC Bus agents, including all processors and the core logic or I/O APIC component. When the APIC is disabled, the LINT0 signal becomes INTR, a maskable interrupt request signal, and LINT1 becomes NMI, a nonmaskable interrupt. INTR and NMI are backward compatible with the signals of those names on the Intel Pentium processor. Both signals are asynchronous. Both of these signals must be software configured via BIOS programming of the APIC register space to be used either as NMI/INTR or LINT[1:0]. Because the APIC is enabled by default after Reset, operation of these pins as LINT[1:0] is the default
		configuration.
LOCK#	I/O	The LOCK# signal indicates to the system that a transaction must occur atomically. This signal must connect the appropriate pins of all processor system bus agents. For a locked sequence of transactions, LOCK# is asserted from the beginning of the first transaction end of the last transaction.
	""	When the priority agent asserts BPRI# to arbitrate for ownership of the processor system bus, it will wait until it observes LOCK# deasserted. This enables symmetric agents to retain ownership of the processor system bus throughout the bus locked operation and ensure the atomicity of lock.
NCHCTRL	I	The NCHCTRL input signal provides AGTL pull-down strength control. The Pentium III processor based on 0.13 micron process samples this input to determine the N-channel device strength for pull-down when it is the driving agent. This signal must be connected to a 14 Ω resistor to VTT. Refer to the platform design guide for implementation detail and resistor tolerance.
PICCLK	I	The PICCLK (APIC Clock) signal is an input clock to the processor and core logic or I/O APIC which is required for operation of all processors, core logic, and I/O APIC components on the APIC bus.
PICD[1:0]	I/O	The PICD[1:0] (APIC Data) signals are used for bidirectional serial message passing on the APIC bus, and must connect the appropriate pins of all processors and core logic or I/O APIC components on the APIC bus.
PLL1, PLL2	I	All Pentium III processors based on 0.13 micron process have an internal analog PLL clock generator that requires a quiet power supply. PLL1 and PLL2 are inputs to this PLL and must be connected to Vcc_{CORE} through a low pass filter that minimizes jitter. See the platform design guide for implementation details.
PRDY#	0	The PRDY (Probe Ready) signal is a processor output used by debug tools to determine processor debug readiness.
PREQ#	I	The PREQ# (Probe Request) signal is used by debug tools to request debug operation of the processors.
PWRGOOD	I	The PWRGOOD (Power Good) signal is processor input. The processor requires this signal to be a clean indication that the clocks and power supplies (Vcc _{CORE} , etc.) are stable and within their specifications. Clean implies that the signal will remain low (capable of sinking leakage current), without glitches, from the time that the power supplies are turned on until they come within specification. The signal must then transition monotonically to a high state. PWRGOOD can be driven inactive at any time, but clocks and power must again be stable before a subsequent rising edge of PWRGOOD. It must also meet the minimum pulse width specification in Table 18, and be followed by a 1 ms RESET# pulse. The PWRGOOD signal must be supplied to the processor; it is used to protect internal circuits against voltage sequencing issues. It should be driven high throughout boundary scan operation.
REQ[4:0]#	I/O	The REQ[4:0]# (Request Command) signals must connect the appropriate pins of all processor system bus agents. They are asserted by the current bus owner over two clock cycles to define the currently active transaction type.

Table 40.	Signal	Description	(Sheet 6	of 8)
-----------	--------	-------------	----------	-------

Name	Туре	Description
		Asserting the RESET# signal resets all processors to known states and invalidates their L1 and L2 caches without writing back any of their contents. For a power-on Reset, RESET# must stay active for at least one millisecond after Vcc _{CORE} and CLK have reached their proper specifications. On observing active RESET#, all processor system bus agents will deassert their outputs within two clocks. A number of bus signals are sampled at the active-to-inactive transition of RESET#
DEDET		for power-on configuration. These configuration options are described in the <i>P6 Family of Processors Hardware Developer's Manual</i> for details.
RESET#	1	The processor may have its outputs tristated via power-on configuration. Otherwise, if INIT# is sampled active during the active-to-inactive transition of RESET#, the processor will execute its Built-in Self-Test (BIST). Whether or not BIST is executed, the processor will begin program execution at the power on Reset vector (default 0_FFFF_FFF0h). RESET# must connect the appropriate pins of all processor system bus agents. RESET# is the only AGTL signal which does not have on-die termination. Therefore, it is necessary to place a discrete 56 Ω resistor to VTT. Refer to the
RESET2#	I	platform design guide for implementation detail and resistor tolerance. RESET2# pin is provided to differentiate the Pentium III processor based on 0.13 micron process from legacy Pentium III processors. The Pentium III processor based on 0.13 micron process does not use the RESET2# pin. Refer to the platform design guide for the proper connections of this signal.
	I/O	The RP# (Request Parity) signal is driven by the request initiator, and provides parity protection on ADS# and REQ[4:0]#. It must connect the appropriate pins of all processor system bus agents.
RP#		A correct parity signal is high if an even number of covered signals are low and low if an odd number of covered signals are low. This definition allows parity to be high when all covered signals are high.
RS[2:0]#	I/O	The RS[2:0]# (Response Status) signals are driven by the response agent (the agent responsible for completion of the current transaction), and must connect the appropriate pins of all processor system bus agents.
RSP#	I	The RSP# (Response Parity) signal is driven by the response agent (the agent responsible for completion of the current transaction) during assertion of RS[2:0]#, the signals for which RSP# provides parity protection. It must connect the appropriate pins of all processor system bus agents.
		A correct parity signal is high if an even number of covered signals are low and low if an odd number of covered signals are low. While RS[2:0]# = 000, RSP# is also high, since this indicates it is not being driven by any agent guaranteeing correct parity.
RTTCTRL	I	The RTTCTRL input signal provides AGTL termination control. The Pentium III processor based on 0.13 micron process samples this input to set the termination resistance value for the on-die AGTL termination. This signal must be connected to a 56 Ω resistor to Vss on a uni-processor platform or a 68 Ω resistor to Vss on a dual-processor platform. Refer to the platform design guide for implementation detail and resistor tolerance.
SLEWCTRL	I	The SLEWCTRL input signal provides AGTL slew rate control. The Pentium III processor based on 0.13 micron process samples this input to determine the slew rate for AGTL signals when it is the driving agent. This signal must be connected to a 110 Ω resistor to Vss. Refer to the platform design guide for implementation detail and resistor tolerance.
SLP#	I	The SLP# (Sleep) signal, when asserted in Stop-Grant state, causes processors to enter the Sleep state. During Sleep state, the processor stops providing internal clock signals to all units, leaving only the Phase-Locked Loop (PLL) still operating. Processors in this state will not recognize snoops or interrupts. The processor will recognize only assertions of the SLP#, STPCLK#, and RESET# signals while in Sleep state. If SLP# is deasserted, the processor exits Sleep state and returns to Stop-Grant state, restarting its internal clock signals to the bus and APIC processor core units.

Table 40. Signal Description (Sheet 7 of 8)

Name	Туре	Description
SMI#	I	The SMI# (System Management Interrupt) signal is asserted asynchronously by system logic. On accepting a System Management Interrupt, processors save the current state and enter System Management Mode (SMM). An SMI Acknowledge transaction is issued, and the processor begins program execution from the SMM handler.
STPCLK#	I	The STPCLK# (Stop Clock) signal, when asserted, causes processors to enter a low power Stop-Grant state. The processor issues a Stop-Grant Acknowledge transaction, and stops providing internal clock signals to all processor core units except the bus and APIC units. The processor continues to snoop bus transactions and latch interrupts while in Stop-Grant state. When STPCLK# is deasserted, the processor restarts its internal clock to all units, services pending interrupts while in the Stop-Grant state, and resumes execution. The assertion of STPCLK# has no effect on the bus clock; STPCLK# is an asynchronous input.
тск	I	The TCK (Test Clock) signal provides the clock input for the processor Test Bus (also known as the Test Access Port).
трі	I	The TDI (Test Data In) signal transfers serial test data into the processor. TDI provides the serial input needed for JTAG specification support.
TDO	0	The TDO (Test Data Out) signal transfers serial test data out of the processor. TDO provides the serial output needed for JTAG specification support.
THERMDN	0	Thermal Diode Cathode. Used to calculate core (junction) temperature. See Section 4.1.
THERMDP	Ι	Thermal Diode Anode. Used to calculate core (junction) temperature. See Section 4.1.
THERMTRIP#	0	The processor protects itself from catastrophic overheating by use of an internal thermal sensor. This sensor is set well above the normal operating temperature to ensure that there are no false trips. The processor will stop all execution when the junction temperature exceeds approximately 135 °C. This is signaled to the system by the THERMTRIP# (Thermal Trip) pin. Once activated, the signal remains latched, and the processor stopped, until RESET# goes active or core power is removed. There is no hysteresis built into the thermal sensor itself; as long as the die temperature drops below the trip level, a RESET# pulse will reset the processor and execution will continue. If the temperature has not dropped below the trip level, the processor will continue to drive THERMTRIP# and remain stopped.
		In the event the processor drives the THERMTRIP# signal active during valid operation, both the VCC and VTT supplies to the processor must be turned off to prevent thermal runaway of the processor. Valid operation refers to the operating conditions where the THERMTRIP# signal is guaranteed valid. The time required from THERMTRIP# asserted to VCC rail at 1/2 nominal is 5 seconds and THERMTRIP# asserted to VTT rail at 1/2 nominal is 5 seconds. Once VCC and VTT supplies are turned off, the THERMTRIP# signal will be deactivated. System logic should ensure no "unsafe" power cycling occurs due to this deassertion.
TMS	I	The TMS (Test Mode Select) signal is a JTAG specification support signal used by debug tools.
TRDY#	I/O	The TRDY# (Target Ready) signal is asserted by the target to indicate that it is ready to receive a write or implicit writeback data transfer. TRDY# must connect the appropriate pins of all processor system bus agents.
TRST#	I	The TRST# (Test Reset) signal resets the Test Access Port (TAP) logic. TRST# must be driven low during power on Reset.
V _{CMOS_REF}	I	The V _{CMOS_REF} input pin supplies non-AGTL reference voltage, which is typically 2/ 3 of V _{CMOS} . V _{CMOS_REF} is used by the non-AGTL receivers to determine if a signal is a logical 0 or a logical 1.

Name	Туре	Description
VID [3:0,25mV]	0	The VID[3:0, 25 mV] (Voltage ID) pins can be used to support automatic selection of power supply voltages. These pins are CMOS signals that must be pulled up to 3.3 V power rail with 1 k Ω resistors. The VID pins are needed to cleanly support voltage specification variations on processors. See Table 3 for definitions of these pins. The power supply must supply the voltage that is requested by these pins, or disable itself.
VREF	I	The VREF input pins supply the AGTL reference voltage, which is typically 2/3 of VTT. VREF is used by the AGTL receivers to determine if a signal is a logical 0 or a logical 1.
VTT_PWRGD	I	The VTT_PWRGD signal informs the system that the VID/BSEL signals are in their correct logic state. During Power-up, the VID signals will be in a indeterminate state for a small period of time. The voltage regulator or the VRM should not sample and/ or latch the VID signals until the VTT_PWRGD signal is asserted. The assertion of the VTT_PWRGD signal indicates the VID signals are stable and are driven to the final state by the processor. Refer to Figure 6 for power-up timing sequence for the VTT_PWRGD and the VID signals.

REQ[4:0]#	Low	BCLK	AGTL I/O	ADS#, ADS#+1
RP#	Low	BCLK	AGTL I/O	ADS#, ADS#+1
RS[2:0]#	Low	BCLK	AGTL Input	Always
TRDY#	Low	BCLK	AGTL Input	

Table 43. Input/Output Signals (Single Driver)

Table 44. Input/Output Signals (Multiple Driver)

Name	Active Level	Clock	Signal Group	Qualified
AERR#	Low	BCLK	AGTL I/O	ADS#+3
BERR#	Low	BCLK	AGTL I/O	Always
BINIT#	Low	BCLK	AGTL I/O	Always
BNR#	Low	BCLK	AGTL I/O	Always
HIT#	Low	BCLK	AGTL I/O	Always
HITM#	Low	BCLK	AGTL I/O	Always
PICD[1:0]	High	PICCLK	APIC I/O	Always
