

## DMOS driver for three-phase brushless DC motor

### Features

- Operating supply voltage from 8 to 52 V
- 2.8 A output peak current (1.4 A RMS)
- $R_{DS(on)}$  0.73  $\Omega$  typ. value @  $T_J = 25\text{ }^\circ\text{C}$
- Operating frequency up to 100 kHz
- Non dissipative overcurrent detection and protection
- Diagnostic output
- Constant  $t_{OFF}$  PWM current controller
- Slow decay synchronous rectification
- 60° and 120° hall effect decoding logic
- Brake function
- Cross conduction protection
- Thermal shutdown
- Under voltage lockout
- Integrated fast free wheeling diodes

### Description

The L6229Q is a DMOS fully integrated three-phase motor driver with overcurrent protection.

Realized in BCDmultipower technology, the device combines isolated DMOS power transistors with CMOS and bipolar circuits on the same chip.

The device includes all the circuitry needed to drive a three-phase BLDC motor including: a three-phase DMOS bridge, a constant off time PWM current controller and the decoding logic for single ended hall sensors that generates the required sequence for the power stage.

Available in VFQFPN-32 5 x 5 package, the L6229Q features a non-dissipative overcurrent protection on the high side power MOSFETs and thermal shutdown.

### 3 Pin connection

Figure 2. Pin connection (top view)

- Note:
- 1 The pins 2 to 8 are connected to die PAD.
  - 2 The die PAD must be connected to GND pin.

Table 5. Pin description

N°	Pin	Type	Function
1, 21	GND	GND	Ground terminals.
9	TACHO	Open drain output	Frequency-to-voltage open drain output. Every pulse from pin H <sub>1</sub> is shaped as a fixed and adjustable length pulse.
11	RCPULSE	RC pin	RC network pin. A parallel RC network connected between this pin and ground sets the duration of the monostable pulse used for the frequency-to-voltage converter.
12	SENSE <sub>B</sub>	Power supply	Half bridge 3 source Pin. This pin must be connected together with pin SENSE <sub>A</sub> to power ground through a sensing power resistor. At this pin also the Inverting Input of the sense comparator is connected.
13	FWD/REV	Logic input	Selects the direction of the rotation. HIGH logic level sets forward operation, whereas LOW logic level sets reverse operation. If not used, it has to be connected to GND or +5 V.
14	EN	Logic input	Chip enable. LOW logic level switches OFF all power MOSFETs. If not used, it has to be connected to +5 V.
15	VREF	Logic input	Current controller reference voltage. Do not leave this pin open or connect to GND.
16	BRAKE	Logic input	Brake input pin. LOW logic level switches ON all high side power MOSFETs, implementing the brake function. If not used, it has to be connected to +5 V.
17	VBOOT	Supply voltage	Bootstrap voltage needed for driving the upper power MOSFETs.
19	OUT <sub>3</sub>	Power output	Output half bridge 3.
20	VS <sub>B</sub>	Power supply	Half bridge 3 power supply voltage. It must be connected to the supply voltage together with pin VS <sub>A</sub> .
22	VS <sub>A</sub>	Power supply	Half bridge 1 and half bridge 2 power supply voltage. It must be connected to the supply voltage together with pin VS <sub>B</sub> .
23	OUT <sub>2</sub>	Power output	Output half bridge 2.
24	VCP	Output	Charge pump oscillator output.
25	H <sub>2</sub>	Sensor input	Single ended hall effect sensor input 2.
26	H <sub>3</sub>	Sensor input	Single ended hall effect sensor input 3.
27	H <sub>1</sub>	Sensor input	Single ended hall effect sensor input 1.
28	DIAG	Open drain output	Overcurrent detection and thermal protection pin. An internal open drain transistor pulls to GND when an overcurrent on one of the high side MOSFETs is detected or during thermal protection.
29	SENSE <sub>A</sub>	Power supply	Half bridge 1 and half bridge 2 source pin. This pin must be connected together with pin SENSE <sub>B</sub> to power ground through a sensing power resistor.
30	RCOFF	RC pin	RC network pin. A parallel RC network connected between this pin and ground sets the current controller OFF-Time.
31	OUT <sub>1</sub>	Power output	Output half bridge 1.

## 4 Electrical characteristics

**Table 6. Electrical characteristics**

## 5 Circuit description

### 5.1 Power stages and charge pump

The L6229Q integrates a three-phase bridge, which consists of 6 power MOSFETs connected as shown on the block diagram (see [Figure 1](#)). Each power MOS has an  $R_{DS(ON)} = 0.73 \Omega$  (typical value @ 25 °C) with intrinsic fast freewheeling diode. Switching patterns are generated by the PWM current controller and the hall effect sensor decoding logic (see relative paragraph 3.3 and 3.5). Cross conduction protection is implemented by using a dead time ( $t_{DT} = 1 \mu s$  typical value) set by internal timing circuit between the turn off and turn on of two power MOSFETs in one leg of a bridge.

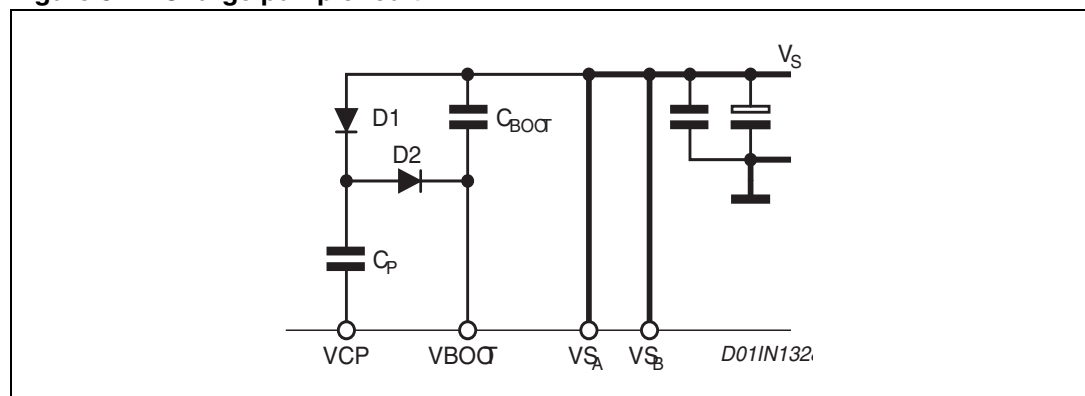

Pins  $VS_A$  and  $VS_B$  must be connected together to the supply voltage ( $V_S$ ).

Using N-channel power MOS for the upper transistors in the bridge requires a gate drive voltage above the power supply voltage. The bootstrapped supply ( $V_{BOOT}$ ) is obtained through an internal oscillator and few external components to realize a charge pump circuit as shown in [Figure 5](#). The oscillator output (pin VCP) is a square wave at 600 kHz (typically) with 10 V amplitude. Recommended values/part numbers for the charge pump circuit are shown in [Table 7](#).

**Table 7. Charge pump external component values**

Component	Value
$C_{BOOT}$	220 nF
$C_P$	10 nF
D1	1N4148
D2	1N4148

**Figure 5. Charge pump circuit**

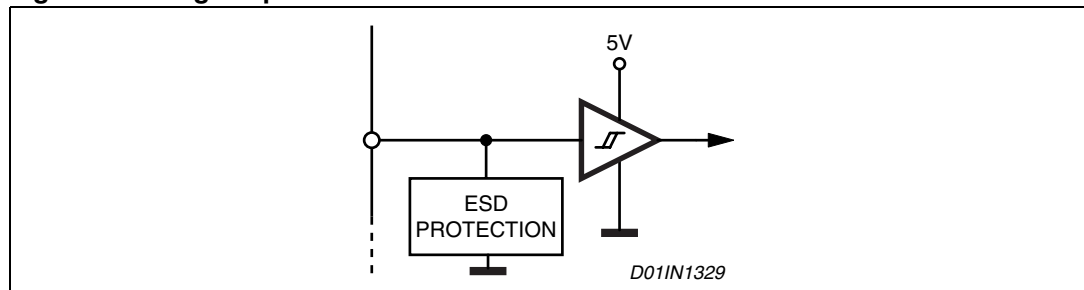

## 5.2 Logic inputs

Pins FWD/REV, BRAKE, EN, H1, H2 and H3 are TTL/CMOS and microcontroller compatible logic inputs. The internal structure is shown in *Figure 6*. Typical value for turn-on and turn-off thresholds are respectively  $V_{th(ON)} = 1.8\text{ V}$  and  $V_{th(OFF)} = 1.3\text{ V}$ .

Pin EN (Enable) has identical input structure with the exception that the drain of the Overcurrent and thermal protection MOSFET is also connected to this pin. Due to this connection some care needs to be taken in driving this pin. The EN input may be driven in one of two configurations as shown in *Figure 10* or *Figure 11*. If driven by an open drain (collector) structure, a pull-up resistor  $R_{EN}$  and a capacitor  $C_{EN}$  are connected as shown in *Figure 10*. If the driver is a standard Push-Pull structure the resistor  $R_{EN}$  and the capacitor  $C_{EN}$  are connected as shown in *Figure 11*. The resistor  $R_{EN}$  should be chosen in the range from 2.2 k $\Omega$  to 180 k $\Omega$ . Recommended values for  $R_{EN}$  and  $C_{EN}$  are respectively 10 k $\Omega$  and 5.6 nF. More information on selecting the values is found in the overcurrent protection section.

**Figure 6. Logic inputs internal structure**

**Figure 7. Pin EN open collector driving**

**Figure 8. Pin EN push-pull driving**

### 5.3 PWM current control

The L6229Q includes a constant off time PWM current controller. The current control circuit senses the bridge current by sensing the voltage drop across an external sense resistor connected between the source of the three lower power MOS transistors and ground, as shown in *Figure 9*. As the current in the motor increases the voltage across the sense resistor increases proportionally. When the voltage drop across the sense resistor becomes greater than the voltage at the reference input pin VREF the sense comparator triggers the monostable switching the bridge off. The power MOS remain off for the time set by the monostable and the motor current recirculates around the upper half of the bridge in slow decay mode as described in the next section. When the monostable times out, the bridge will again turn on. Since the internal dead time, used to prevent cross conduction in the bridge, delays the turn on of the power MOS, the effective off time  $t_{OFF}$  is the sum of the monostable time plus the dead time.

*Figure 10* shows the typical operating waveforms of the output current, the voltage drop across the sensing resistor, the pin RC voltage and the status of the bridge. More details regarding the synchronous rectification and the output stage configuration are included in the next section.

Immediately after the power MOS turn on, a high peak current flows through the sense resistor due to the reverse recovery of the freewheeling diodes. The L6229Q provides a 1 μs blanking time  $t_{BLANK}$  that inhibits the comparator output so that the current spike cannot prematurely re trigger the monostable.

**Figure 9. PWM current controller simplified schematic**

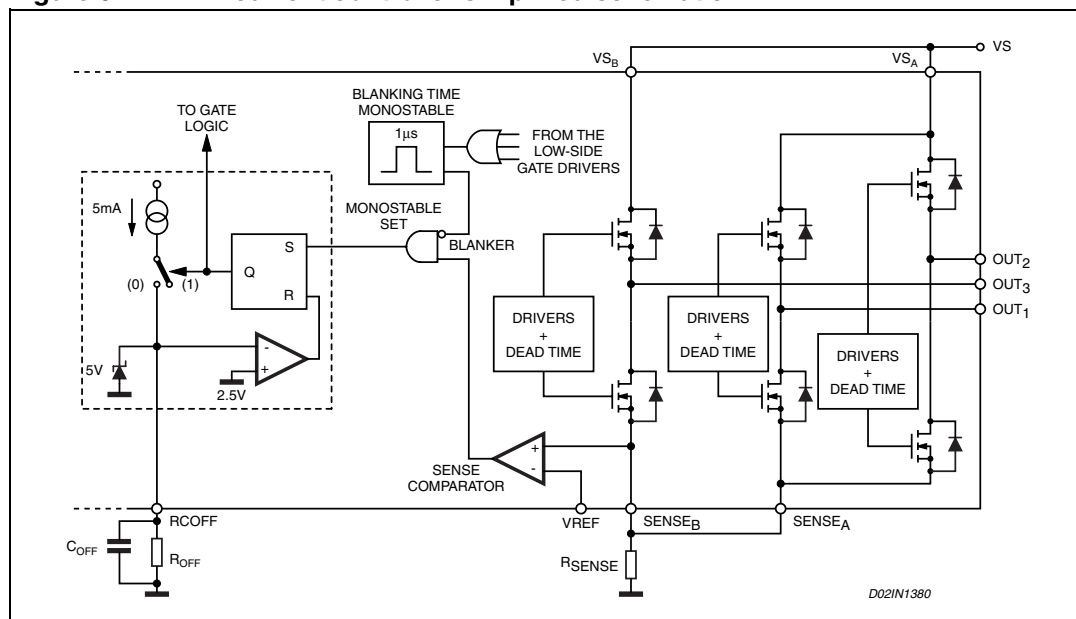

Figure 10. Output current regulation waveforms

Figure 11 shows the magnitude of the Off Time  $t_{OFF}$  versus  $C_{OFF}$  and  $R_{OFF}$  values. It can be approximately calculated from the equations:

$$t_{RCFALL} = 0.6 \cdot R_{OFF} \cdot C_{OFF}$$

$$t_{OFF} = t_{RCFALL} + t_{DT} = 0.6 \cdot R_{OFF} \cdot C_{OFF} + t_{DT}$$

where  $R_{OFF}$  and  $C_{OFF}$  are the external component values and  $t_{DT}$  is the internally generated Dead Time with:

$$20 \text{ k}\Omega \leq R_{OFF} \leq 100 \text{ k}\Omega$$

$$0.47 \text{ nF} \leq C_{OFF} \leq 100 \text{ nF}$$

$$t_{DT} = 1 \text{ }\mu\text{s (typical value)}$$

Therefore:

$$t_{OFF(MIN)} = 6.6 \text{ }\mu\text{s}$$

$$t_{OFF(MAX)} = 6 \text{ ms}$$

These values allow a sufficient range of  $t_{OFF}$  to implement the drive circuit for most motors.

The capacitor value chosen for  $C_{OFF}$  also affects the Rise Time  $t_{RCRISE}$  of the voltage at the pin RCOFF. The rise time  $t_{RCRISE}$  will only be an issue if the capacitor is not completely charged before the next time the monostable is triggered. Therefore, the on time  $t_{ON}$ , which depends by motors and supply parameters, has to be bigger than  $t_{RCRISE}$  for allowing a good current regulation by the PWM stage. Furthermore, the on time  $t_{ON}$  can not be smaller than the minimum on time  $t_{ON(MIN)}$ .

$$\begin{cases} t_{ON} > t_{ON(MIN)} = 2.5\mu s & (\text{typ. value}) \\ t_{ON} > t_{RCRISE} - t_{DT} \end{cases}$$

$$t_{RCRISE} = 600 \cdot C_{OFF}$$

Figure 12 shows the lower limit for the on time  $t_{ON}$  for having a good PWM current regulation capacity. It has to be said that  $t_{ON}$  is always bigger than  $t_{ON(MIN)}$  because the device imposes this condition, but it can be smaller than  $t_{RCRISE} - t_{DT}$ . In this last case the device continues to work but the off time  $t_{OFF}$  is not more constant.

So, small  $C_{OFF}$  value gives more flexibility for the applications (allows smaller on time and, therefore, higher switching frequency), but, the smaller is the value for  $C_{OFF}$  the more influential will be the noises on the circuit performance.

Figure 11.  $t_{OFF}$  versus  $C_{OFF}$  and  $R_{OFF}$

Figure 12. Area where  $t_{ON}$  can vary maintaining the PWM regulation

## 5.4 Slow decay mode

*Figure 13* shows the operation of the bridge in the slow decay mode during the off time. At any time only two legs of the three-phase bridge are active, therefore only the two active legs of the bridge are shown in the figure and the third leg will be off. At the start of the Off Time, the lower power MOS is switched off and the current recirculates around the upper half of the bridge. Since the voltage across the coil is low, the current decays slowly. After the dead time the upper power MOS is operated in the synchronous rectification mode reducing the impedance of the freewheeling diode and the related conducting losses. When the monostable times out, upper MOS that was operating the synchronous mode turns off and the lower power MOS is turned on again after some delay set by the dead time to prevent cross conduction.

**Figure 13. Slow decay mode output stage configurations**

## 5.5 Decoding logic

The decoding logic section is a combinatory logic that provides the appropriate driving of the three-phase bridge outputs according to the signals coming from the three hall sensors that detect rotor position in a 3-phase BLDC motor. This novel combinatory logic discriminates between the actual sensor positions for sensors spaced at 60, 120, 240 and 300 electrical degrees. This decoding method allows the implementation of a universal IC without dedicating pins to select the sensor configuration.

There are eight possible input combinations for three sensor inputs. Six combinations are valid for rotor positions with 120 electrical degrees sensor phasing (see *Figure 14*, positions 1, 2, 3a, 4, 5 and 6a) and six combinations are valid for rotor positions with 60 electrical degrees phasing (see *Figure 15*, positions 1, 2, 3b, 4, 5 and 6b). Four of them are in common (1, 2, 4 and 5) whereas there are two combinations used only in 120 electrical degrees sensor phasing (3a and 6a) and two combinations used only in 60 electrical degrees sensor phasing (3b and 6b).

The decoder can drive motors with different sensor configuration simply by following the *Table 8*. For any input configuration ( $H_1$ ,  $H_2$  and  $H_3$ ) there is one output configuration ( $OUT_1$ ,  $OUT_2$  and  $OUT_3$ ). The output configuration 3a is the same than 3b and analogously output configuration 6a is the same than 6b.

The sequence of the Hall codes for 300 electrical degrees phasing is the reverse of 60 and the sequence of the Hall codes for 240 phasing is the reverse of 120. So, by decoding the 60

and the 120 codes it is possible to drive the motor with all the four conventions by changing the direction set.

**Table 8. 60 and 120 electrical degree decoding logic in forward direction**

Hall 120°	1	2	3a	-	4	5	6a	-
Hall 60°	1	2	-	3b	4	5	-	6b
H <sub>1</sub>	H	H	L	H	L	L	H	L

**Figure 14. 120° hall sensor sequence**

**Figure 15. 60° hall sensor sequence**

## 5.6 Tacho

A tachometer function consists of a monostable, with constant off time ( $t_{PULSE}$ ), whose input is one hall effect signal ( $H_1$ ). It allows developing an easy speed control loop by using an external op amp, as shown in [Figure 17](#). For component values refer to Application Information section.

The monostable output drives an open drain output pin (TACHO). At each rising edge of the hall effect sensors  $H_1$ , the monostable is triggered and the MOSFET connected to pin TACHO is turned off for a constant time  $t_{PULSE}$  (see [Figure 16](#)). The off time  $t_{PULSE}$  can be set using the external RC network ( $R_{PUL}$ ,  $C_{PUL}$ ) connected to the pin RCPULSE. [Figure 18](#) gives the relation between  $t_{PULSE}$  and  $C_{PUL}$ ,  $R_{PUL}$ . We have approximately:

$$t_{PULSE} = 0.6 \cdot R_{PUL} \cdot C_{PUL}$$

where  $C_{PUL}$  should be chosen in the range 1 nF ... 100 nF and  $R_{PUL}$  in the range 20 k $\Omega$  ... 100 k $\Omega$ .

By connecting the tachometer pin to an external pull-up resistor, the output signal average value  $V_M$  is proportional to the frequency of the hall effect signal and, therefore, to the motor speed. This realizes a simple frequency-to-voltage converter. An op amp, configured as an integrator, filters the signal and compares it with a reference voltage  $V_{REF}$  which sets the speed of the motor.

$$V_M = \frac{t_{PULSE}}{T} \cdot V_{DD}$$

**Figure 16. Tacho operation waveforms**

Figure 17. Tachometer speed control loop

Figure 18.  $t_{PULSE}$  versus  $C_{PUL}$  and  $R_{PUL}$

## 5.7 Non-dissipative overcurrent detection and protection

The L6229Q integrates an overcurrent detection circuit (OCD) for full protection. This circuit provides output-to-output and output-to-ground short circuit protection as well. With this internal over current detection, the external current sense resistor normally used and its associated power dissipation are eliminated. *Figure 19* shows a simplified schematic for the overcurrent detection circuit.

To implement the over current detection, a sensing element that delivers a small but precise fraction of the output current is implemented with each high side power MOS. Since this current is a small fraction of the output current there is very little additional power dissipation. This current is compared with an internal reference current  $I_{REF}$ . When the output current reaches the detection threshold (typically  $I_{SOVER} = 2.8\text{ A}$ ) the OCD comparator signals a fault condition. When a fault condition is detected, an internal open drain MOS with a pull down capability of 4 mA connected to pin DIAG is turned on.

The pin DIAG can be used to signal the fault condition to a  $\mu\text{C}$  or to shut down the three-phase bridge simply by connecting it to pin EN and adding an external R-C (see  $R_{EN}$ ,  $C_{EN}$ ).

**Figure 19. Overcurrent protection simplified schematic**

*Figure 20* shows the overcurrent detection operation. The disable time  $t_{DISABLE}$  before recovering normal operation can be easily programmed by means of the accurate thresholds of the logic inputs. It is affected whether by  $C_{EN}$  and  $R_{EN}$  values and its magnitude is reported in *Figure 21*. The delay time  $t_{DELAY}$  before turning off the bridge when an overcurrent has been detected depends only by  $C_{EN}$  value. Its magnitude is reported in *Figure 22*

$C_{EN}$  is also used for providing immunity to pin EN against fast transient noises. Therefore the value of  $C_{EN}$  should be chosen as big as possible according to the maximum tolerable delay time and the  $R_{EN}$  value should be chosen according to the desired disable time.

The resistor  $R_{EN}$  should be chosen in the range from 2.2 k $\Omega$  to 180 k $\Omega$ . Recommended values for  $R_{EN}$  and  $C_{EN}$  are respectively 100 k $\Omega$  and 5.6 nF that allow obtaining 200  $\mu\text{s}$  disable time.

## 6 Application information

A typical application using L6229Q is shown in [Figure 23](#). Typical component values for the application are shown in [Table 9](#). A high quality ceramic capacitor ( $C_2$ ) in the range of 100 nF to 200 nF should be placed between the power pins  $VS_A$  and  $VS_B$  and ground near the L6229Q to improve the high frequency filtering on the power supply and reduce high frequency transients generated by the switching. The capacitor ( $C_{EN}$ ) connected from the EN input to ground sets the shut down time when an over current is detected (see overcurrent protection). The two current sensing inputs ( $SENSE_A$  and  $SENSE_B$ ) should be connected to the sensing resistor  $R_{SENSE}$  with a trace length as short as possible in the layout. The sense resistor should be non-inductive resistor to minimize the  $di/dt$  transients across the resistor. To increase noise immunity, unused logic pins are best connected to 5 V (high logic level) or GND (low logic level) (see pin description). It is recommended to keep power ground and signal ground separated on PCB.

**Table 9. Component values for typical application**

Component	Value
$C_1$	100 $\mu$ F
$C_2$	100 nF
$C_3$	220 nF
$C_{BOOT}$	220 nF
$C_{OFF}$	1 nF
$C_{PUL}$	10 nF
$C_{REF1}$	33 nF
$C_{REF2}$	100 nF
$C_{EN}$	5.6 nF
$C_P$	10 nF
$D_1$	1N4148
$D_2$	1N4148
$R_1$	5 k $\Omega$
$R_2$	1 k $\Omega$
$R_3$	4 k $\Omega$
$R_4$	1 M $\Omega$
$R_{DD}$	1 k $\Omega$
$R_{EN}$	100 k $\Omega$
$R_{SENSE}$	0.6 $\Omega$
$R_{OFF}$	33 k $\Omega$
$R_{PUL}$	47 k $\Omega$
$R_{H1}, R_{H2}, R_{H3}$	10 k $\Omega$

Figure 23. Typical application

## 6.1 Output current capability and ic power dissipation

In [Figure 24](#) is shown the approximate relation between the output current and the IC power dissipation using PWM current control.

For a given output current the power dissipated by the IC can be easily evaluated, in order to establish which package should be used and how large must be the on-board copper dissipating area to guarantee a safe operating junction temperature (125 °C maximum).

Figure 24. IC power dissipation versus output power

## 6.2 Thermal management

In most applications the power dissipation in the IC is the main factor that sets the maximum current that can be delivered by the device in a safe operating condition. Therefore, it has to be taken into account very carefully. Besides the available space on the PCB, the right package should be chosen considering the power dissipation. Heat sinking can be achieved using copper on the PCB with proper area and thickness.

For instance, using a VFQFPN32L 5 x 5 package the typical  $R_{th(JA)}$  is about 42 °C/W when mounted on a double-layer FR4 PCB with a dissipating copper area of 0.5 cm<sup>2</sup> on the top side plus 6 cm<sup>2</sup> ground layer connected through 18 via holes (9 below the IC).

## 7 Package mechanical data

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK® packages, depending on their level of environmental compliance. ECOPACK® specifications, grade definitions and product status are available at: [www.st.com](http://www.st.com). ECOPACK® is an ST trademark.

**Table 10. VFQFPN 5 x 5 x 1.0, 32 lead, pitch 0.50**

Dim.	Databook (mm)		
	Min	Typ	Max
A	0.80	0.85	0.95
b	0.18	0.25	0.30
b1	0.165	0.175	0.185
D	4.85	5.00	5.15
D2	3.00	3.10	3.20
D3	1.10	1.20	1.30
E	4.85	5.00	5.15
E2	4.20	4.30	4.40
E3	0.60	0.70	0.80
e		0.50	
L	0.30	0.40	0.50
ddd			0.08

*Note:* VFQFPN stands for thermally enhanced very thin profile fine pitch quad flat package no lead. Very thin profile:  $0.80 < A < 1.00$  mm.

*Details of terminal 1 are optional but must be located on the top surface of the package by using either a mold or marked features.*
