

1°C Triple SMBus Sensor with Resistance Error Correction

PRODUCT FEATURES

Datasheet

General Description

The EMC1033 is an SMBus temperature sensor that monitors up to three temperature zones and can generate two system interrupts. With $\pm 1^\circ\text{C}$ measurement accuracy, the EMC1033 provides a low-cost solution for critical temperature monitoring applications. Features include automatic resistance error correction and programmable ideality factor configuration eliminating both major sources of temperature measurement error.¹

The EMC1033 generates two separate interrupts with programmable thermal trip points. The $\overline{\text{THERM}}$ output operates as a thermostat with programmable threshold and hysteresis. The $\overline{\text{ALERT}}$ output can be configured as a maskable SMBus alert with programmable window comparator limits, or as a second $\overline{\text{THERM}}$ output. Both interrupts are maintained in an 8-pin package while a third temperature zone is added with the anti-parallel diode technique. This allows the EMC1033 to be pin compatible with the ADT7461, ADM1032, LM99, and the MAX6649 with the advantage of a third temperature zone.

¹. Patents pending.

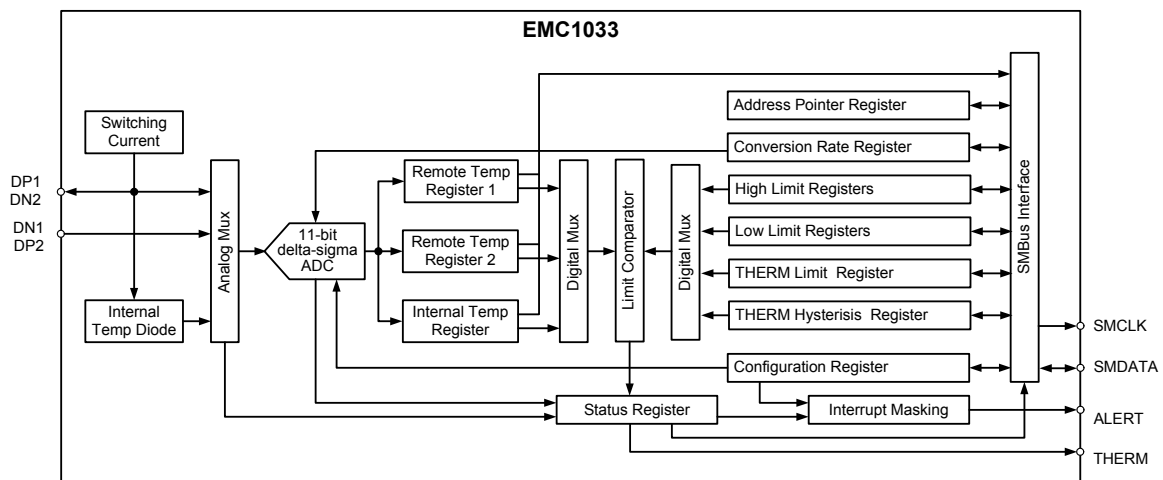

Features

- Resistance Error Correction
- Ideality Factor Configuration
- Select 1 of 4 SMBus addresses with external resistor
- Remote Thermal Zones
 - $\pm 1.0^\circ\text{C}$ Accuracy (40°C to 80°C)
 - 0.125°C resolution
- Internal Thermal Zone
 - $\pm 3.0^\circ\text{C}$ Accuracy (0°C to 85°C)
- Maskable Interrupt using $\overline{\text{ALERT}}$
- One-shot Command during standby
- Programmable temperature conversion rate
- Extended temperature (-64°C to 191°C) available
- Over-limit filtering with consecutive counter
- Small 8-pin SOIC or TSSOP lead-free RoHS compliant package

Applications

- Desktop and Notebook Computers
- Thermostats
- Smart batteries
- Industrial/Automotive

Chapter 1 Pin Configuration

Figure 1.1 EMC1033 Pin Configuration

Table 1.1 Pin Description

PIN	PIN NO.	DESCRIPTION
V _{DD}	1	Supply Voltage, 3.0V to 3.6V.
DP1/DN2	2	Anode connection for remote temperature diode 1 and cathode connection for remote temperature diode 2.
DN1/DP2	3	Cathode connection for remote temperature diode1 and anode connection for remote temperature diode 2.
ADDR/THERM	4	Logic output that can be used to turn on/off a fan or throttle a CPU clock in the event of an over-temperature condition. This is an open-drain output. This pin is sampled following reset and the value of the pull up resistor determines the SMBus slave address per Table 1.2 on page 3 . Total capacitance on this pin must not exceed 100 pF, and the pull-up resistor must be connected to the same supply voltage as V _{DD} .
GND	5	Ground.
ALERT/THERM2	6	Logic output used as interrupt, SMBus alert or as a second THERM output. This is an open-drain output.
SMDATA	7	SMBus data input/output. This is an open-drain output.
SMCLK	8	SMBus clock input.

Table 1.2 SMBus Slave Address

ADDR/THERM PULL-UP RESISTOR	SMBUS ADDRESS
7.5kΩ ±5% Note 1.1 Note 1.2	1001 100b
12kΩ ±5% Note 1.2	1001 101b
20kΩ ±5% Note 1.2	0111 100b
33kΩ ±5% Note 1.2	0111 101b

Note 1.1 This value must be greater than 1kΩ ±5% and less than or equal to 7.5kΩ ±5%.

Note 1.2 The pull-up resistor must be connected to V_{DD} (pin 1), and the total capacitance on this pin must be less than 100pF.

Table 1.3 Absolute Maximum Ratings

PARAMETER	RATING	UNIT
Supply Voltage V_{DD}	-0.3 to 5.0	V
Voltage on $\overline{ALERT}/\overline{THERM2}$, SMDATA and \overline{SMCLK} pins	-0.3 to 5.5	V
Voltage on any other pin	-0.3 to $V_{DD}+0.3$	V
Operating Temperature Range	-40 to +125	°C
Storage Temperature Range	-55 to +150	°C
Lead Temperature Range	Refer to JEDEC Spec. J-STD-020	
Package Thermal Characteristics for MSOP-8		
Power Dissipation	TBD	
Thermal Resistance (at 0 air flow)	109.6	°C/W
Package Thermal Characteristics for SOIC-8		
Power Dissipation	TBD	
Thermal Resistance (at 0 air flow)	135.9	°C/W
ESD Rating, All Pins (Human Body Model)	2000	V

Note: Stresses above those listed could cause damage to the device. This is a stress rating only and functional operation of the device at any other condition above those indicated in the operation sections of this specification is not implied. When powering this device from laboratory or system power supplies, it is important that the Absolute Maximum Ratings not be exceeded or device failure can result. Some power supplies exhibit voltage spikes on their outputs when the AC power is switched on or off. In addition, voltage transients on the AC power line may appear on the DC output. If this possibility exists, it is suggested that a clamp circuit be used.

Chapter 2 Electrical Characteristics

Table 2.1 Electrical Characteristics

Capacitive Load (each bus line)	C _b	0.6		400	pF	

Note 2.1 300nS rise time max is required for 400kHz bus operation. For lower clock frequencies, the maximum rise time is (0.1/F_{SMB})+50nS

Chapter 3 System Management Bus Interface Protocol

A host controller, such as an SMSC I/O controller, communicates with the EMC1033 via the two wire serial interface named SMBus. The SMBus interface is used to read and write registers in the EMC1033, which is a slave-only device. A detailed timing diagram is shown in [Figure 3.1](#).

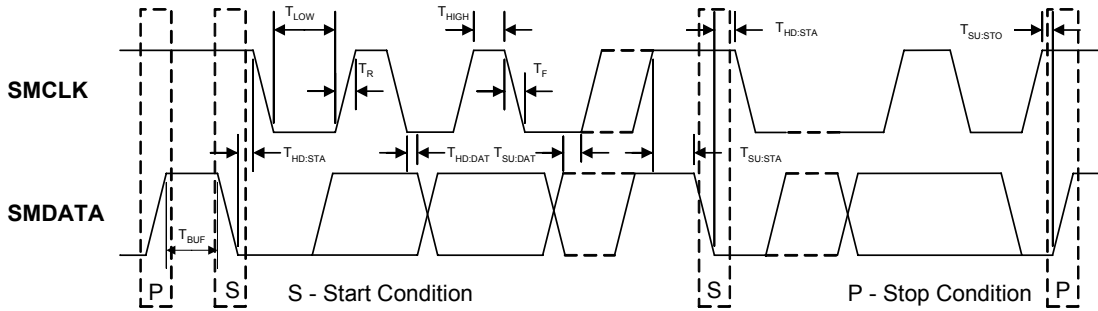

Figure 3.1 System Management Bus Timing Diagram

The EMC1033 implements a subset of the SMBus specification and supports Write Byte, Read Byte, Send Byte, Receive Byte, and Alert Response Address protocols. as shown. In the tables that describe the protocol, the “gray” columns indicate that the slave is driving the bus.

3.1 Write Byte

The Write Byte protocol is used to write one byte of data to the registers as shown below:

Table 3.1 SMBus Write Byte Protocol

START	SLAVE ADDRESS	WR	ACK	COMMAND	ACK	DATA	ACK	STOP
1	7	1	1	8	1	8	1	1

3.2 Read Byte

The Read Byte protocol is used to read one byte of data from the registers as shown below:

Table 3.2 SMBus Read Byte Protocol

START	SLAVE ADDRESS	WR	ACK	COMMAND	ACK	START	SLAVE ADDRESS	RD	ACK	DATA	NACK	STOP
1	7	1	1	8	1	1	7	1	1	8	1	1

3.3 Send Byte

The Send Byte protocol is used to set the Internal Address Register to the correct Address. The Send Byte can be followed by the Receive Byte protocol described below in order to read data from the register. The send byte protocol cannot be used to write data - if data is to be written to a register then the write byte protocol must be used as described in subsection above. The send byte protocol is shown in [Table 3.3](#), “SMBus Send Byte Protocol,” on page 7.

Table 3.3 SMBus Send Byte Protocol

FIELD:	START	SLAVE ADDR	WR	ACK	REG. ADDR	ACK	STOP
Bits:	1	7	1	1	8	1	1

3.4 Receive Byte

The Receive Byte protocol is used to read data from a register when the internal register address pointer is known to be at the right location (e.g. set via Send Byte). This can be used for consecutive reads of the same register as shown below:

Table 3.4 SMBus Receive Byte Protocol

FIELD:	START	SLAVE ADDR	RD	ACK	REG. DATA	NACK	STOP
Bits:	1	7	1	1	8	1	1

3.5 Alert Response Address

The $\overline{\text{ALERT/THERM2}}$ output can be used as an SMBALERT# as described in [Section 4.5 on page 12](#). The Alert Response Address is polled by the Host whenever it detects an SMBALERT#, i.e. when the $\overline{\text{ALERT/THERM2}}$ pin is asserted. The EMC1033 will acknowledge the Alert Response Address and respond with its device address as shown below.

Table 3.5 Modified SMBus Receive Byte Protocol Response to ARA

FIELD:	START	ALERT RESPONSE ADDRESS	RD	ACK	EMC1033 SLAVE ADDRESS	NACK	STOP
Bits:	1	7	1	1	8	1	1

3.6 SMBus Addresses

The EMC1033 may be configured to one of four 7-bit slave addresses that are enabled based on the pull-up resistor on the ADDR/THERM pin. The value of this pull up resistor determines the slave address per [Table 1.2 on page 3](#). Attempting to communicate with the EMC1033 SMBus interface with an invalid slave address or invalid protocol results in no response from the device and does not affect its register contents. The EMC1033 supports stretching of the SMCLK signal by other devices on the SMBus but will not perform this operation itself. The EMC1033 has an SMBus timeout feature. Bit 7 of the Consecutive Alert register enables this function when set to 1 (the default setting is 0). When this feature is enabled, the SMBus will timeout after approximately 25ms of inactivity.

Chapter 4 Product Description

The EMC1033 is an SMBus sensor that can monitor internal temperature and one or two remote diode temperatures. The sensor is typically used with an SMBus host such as an SMSC SIO device or an SMSC fan control chip.

Thermal management is performed in cooperation with the host device. The host reads the temperature data from the EMC1033 and takes appropriate action such as controlling fan speed or processor clock frequency. The EMC1033 has programmable temperature limit registers that define a safe operating window. After the host has configured the temperature limits, the EMC1033 can perform as a free-running independent watchdog to warn the host of temperature hot spots without requiring the host to poll the device.

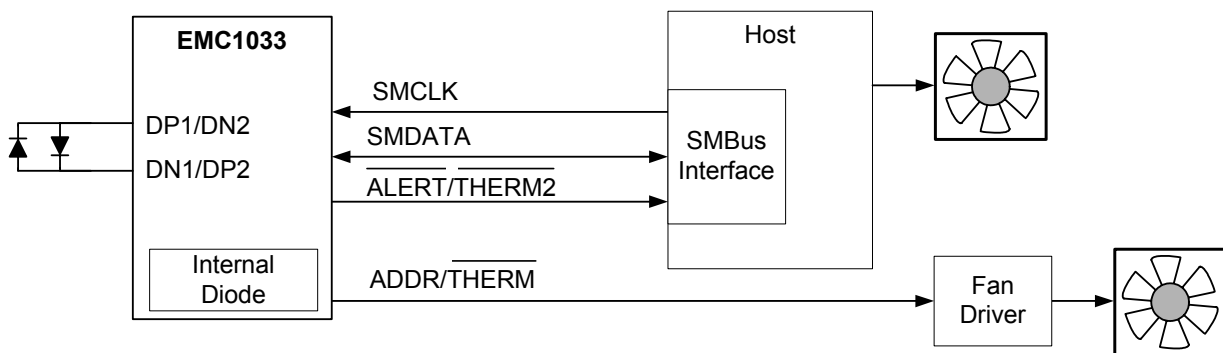

Figure 4.1 System Overview

Two separate temperature zones are monitored using only two pins on the EMC1033. This is accomplished using two anti-parallel diodes as shown in [Figure 4.1](#). This technique maintains high accuracy while minimizing pin count and reducing board routing complexity. The anti-parallel diode architecture performs very well with diode connected transistors. It is not compatible with substrate transistors (sometimes called thermal diodes or on-chip sense junctions). See the complete list of temperature sensor products available from SMSC for devices that can measure two or more remote zones including substrate transistors. The connections for the two discrete transistors are shown in [Figure 4.2](#).

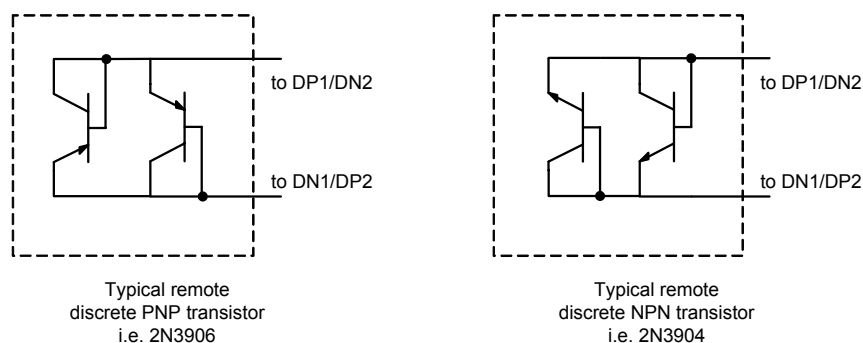

Figure 4.2 Anti-parallel Diodes

The EMC1033 has two basic modes of operation:

- **Run Mode:** In this mode, the EMC1033 continuously converts temperature data and updates its registers. The rate of temperature conversion is configured as shown in [Section 4.12, "Conversion Rate Register,"](#) on page 17.
- **Standby Mode:** In this mode, the EMC1033 is placed in standby to conserve power as described in [Section 4.7, "Standby Mode,"](#) on page 13.

4.1 Temperature Monitors

Thermal diode temperature measurements are based on the change in forward bias voltage (ΔV_{BE}) of a diode when operated at two different currents:

$$\Delta V_{BE} = V_{BE_HIGH} - V_{BE_LOW} = \frac{\eta k T}{q} \ln \left(\frac{I_{HIGH}}{I_{LOW}} \right)$$

where:

k = Boltzmann's constant

T = absolute temperature in Kelvin

q = electron charge

η = diode ideality factor

The change in ΔV_{BE} voltage is proportional to absolute temperature T .

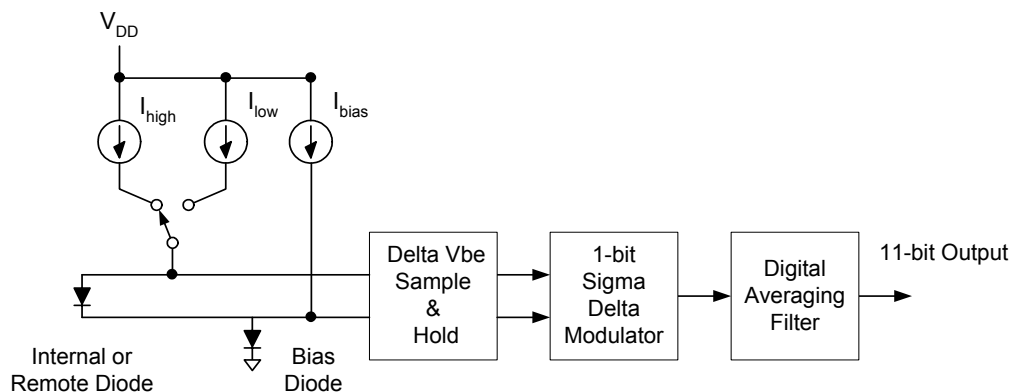

Figure 4.3 Detailed Block Diagram

Figure 4.3 shows a detailed block diagram of the temperature measurement circuit. The EMC1033 incorporates switched capacitor technology that integrates the temperature diode ΔV_{BE} from different bias currents. The negative terminal, DN, for the temperature diode is internally biased with a forward diode voltage referenced to ground.

The advantages of this architecture over Nyquist rate FLASH or SAR converters are superb linearity and inherent noise immunity. The linearity can be directly attributed to the delta-sigma ADC single-bit comparator while the noise immunity is achieved by the ~20ms integration time which translates to 50Hz input noise bandwidth.

4.2 Resistance Error Correction

The EMC1033 includes active resistance error correction implemented in the analog front end of the chip. Without this automatic feature, voltage developed across the parasitic resistance in the remote diode path causes the temperature to read higher than the true zone temperature. The error introduced by parasitic resistance is approximately +0.7°C per ohm. Sources of parasitic resistance include bulk resistance in the remote temperature transistor junctions along with resistance in the printed circuit board traces and package leads.

Resistance error correction in the EMC1033 eliminates the need to characterize and compensate for parasitic resistance in the remote diode path.

4.3 Programmable Ideality Factor

Temperature sensors like the EMC1033 are typically designed for remote diodes with an ideality factor of 1.008. When the diode does not have this exact factor, an error is introduced in the temperature measurement. Programmable offset registers are sometimes used to compensate for this error, but this correction is only perfect at one temperature since the error introduced by ideality factor mismatch

Datasheet

is a function of temperature. The higher the temperature measured, the greater the error introduced. To provide maximum flexibility to the user, the EMC1033 provides a 6-bit ideality factor register for each remote diode. The ideality factor of the remote diode is programmed in these registers to eliminate errors across all temperatures. See section [Section 4.18, "Ideality Factor Register,"](#) on [page 19](#) for details on programming these registers.

4.4 Temperature Measurement Results and Data

The 11-bit temperature measurement results are stored in temperature value registers. The EMC1033 has two temperature ranges and the default range is from 0 to 127°C. This range uses binary number format, and the most significant bit is not used. The extended range is from -64°C to +191°C and is binary offset by 64°C. [Table 4.1](#) shows the two temperature data formats with an LSB equivalent to 0.125°C. The format is selected as described in [Section 4.11, "Configuration Register,"](#) on [page 16](#)

Table 4.1 Temperature Data Format

ACTUAL TEMP. (°C)	DEFAULT RANGE BINARY	EXTENDED RANGE OFFSET BINARY
-63	0000 0000 000 Note 4.1	0000 0001 000 Note 4.2
-0.125	0000 0000 000 Note 4.1	0011 1111 111
0	0000 0000 000 Note 4.1	0100 0000 000
+0.125	0000 0000 001	0100 0000 001
+0.250	0000 0000 010	0100 0000 010
+1	0000 0001 000	0100 0001 000
+127	0111 1111 000 Note 4.3	1011 1110 000
+128	0111 1111 000 Note 4.3	1011 1111 000
+190	0111 1111 000 Note 4.3	1111 1110 000
+191	0111 1111 000 Note 4.3	1111 1111 000 Note 4.4

Note 4.1 Data in Binary Format reads 0000 0000 000 for all temperatures $\leq 0.00^\circ\text{C}$

Note 4.2 Data in Offset Binary Format reads 0000 0000 000 for all temperatures $\leq -64^\circ\text{C}$

Note 4.3 Data in Binary Format reads 0111 1111 000 for all temperatures $\geq +127^\circ\text{C}$

Note 4.4 Data in Offset Binary Format reads 1111 1111 000 for all temperatures $\geq +191^\circ\text{C}$

The 11-bit temperature data is stored with the 8 most significant bits stored in the High Byte register and the 3 least significant bits in the Low Byte register. The Low Byte register contains the three least significant bits as outlined in [Table 4.2](#). These bits are stored in the upper three bits of the register, and the five LSB positions of this register always read zero. In [Table 4.2](#), the upper case "B" shows the bit position of a 16-bit word created by concatenating the High Byte and Low Byte, and the lower case "b" shows the bit position in the 11-bit temperature data. The resolution of the internal temperature is 0.5°C and the b1 and b0 bits of the Internal Temperature Value Low Byte register will always read 0.

Table 4.2 Bit Position of Two Byte Values

HIGH BYTE								LOW BYTE							
B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0	0	0	0	0	0

4.5 ALERT/THERM2 Output

The $\overline{\text{ALERT/THERM2}}$ output asserts if an out of limit measurement is detected as described in [Section 4.13, "Limit Registers," on page 17](#). The $\overline{\text{ALERT/THERM2}}$ pin is an open drain output and requires a pull up resistor to V_{DD} . The $\overline{\text{ALERT/THERM2}}$ pin can be used as an SMBALERT#, or may be configured as a second THERM output.

As described in the SMBus specification, an SMBus slave may inform the SMBus master that it wants to talk by asserting the SMBALERT# signal. One or more $\overline{\text{ALERT}}$ outputs can be hardwired together as a wired-or bus to a common input.

The $\overline{\text{ALERT/THERM2}}$ pin de-asserts when the EMC1033 responds to an alert response address (ARA=0001 100) sent by the host, and if the out of limit condition no longer exists. It does not reset if the error condition remains. The $\overline{\text{ALERT/THERM2}}$ pin can be masked so that it will not assert in the event of an out of limit temperature measurement, except when it is configured as a second THERM pin.

Figure 4.4 $\overline{\text{ALERT/THERM2}}$ Response to Temperature Limits Exceeded

The $\overline{\text{ALERT/THERM2}}$ pin can be configured as a second THERM pin that asserts when the temperature measurement exceeds the Temperature High Limit value. In this mode, the output will not de-assert until the temperature drops below the Temperature High Limit minus the THERM Hysteresis value.

4.6 ADDR/THERM Output

The ADDR/THERM output asserts if the temperature measurement exceeds the programmable THERM limit. It can be used to drive a fan or other fail-safe devices. The ADDR/THERM pin is open drain and requires a pull up resistor to V_{DD} . The value of this pull up resistor determines the slave address per [Table 1.2 on page 3](#). The ADDR/THERM pin cannot be masked.

When the ADDR/THERM pin is asserted, it will not de-assert until the temperature drops below the THERM limit minus the THERM hysteresis value.

Figure 4.5 $\overline{\text{ADDR/THERM}}$ Output Response to Temperature Limit Exceeded

4.7 Standby Mode

The EMC1033 can be set to standby mode (low power) by setting a bit in the Configuration Register as described in [Section 4.11, "Configuration Register," on page 16](#). This shuts down all internal analog functions and the SMBus remains enabled. When the EMC1033 is in standby mode, a One-Shot command measurement can be initiated. The user may also write new values to the limit registers described in [Section 4.13, "Limit Registers," on page 17](#) while in standby. If the previously stored temperature is outside any of the new limits, the $\overline{\text{ALERT/THERM2}}$ output will respond as described in [Section 4.5](#) and the $\overline{\text{ADDR/THERM}}$ output will respond as described in [Section 4.6](#).

4.8 Register Allocation

The registers shown in [Table 4.3](#) are accessible through the SMBus.

Table 4.3 EMC1033 Register Map

READ ADDRESS (HEX)	WRITE ADDRESS (HEX)	REGISTER NAME	POWER-ON DEFAULT

Note 4.5 Revision number may change. Please obtain the latest version of this document from the SMSC web site.

At device power-up, the default values are stored in registers as shown. A power-on-reset is initiated when power is first applied to the part and the V_{DD} supply exceeds the POR threshold. Reads of undefined registers will return 00h and writes to undefined registers will be ignored.

Datasheet

The EMC1033 uses an interlock mechanism that locks the low byte value when the high byte register is read. This prevents updates to the low byte register between high byte and low byte reads. This interlock mechanism requires that the high byte register always be read prior to reading the low byte register.

4.9 Status Register

The status register is a read only register that stores the operational status of the part.

Table 4.4 Status Register

STATUS REGISTER		
BIT	NAME	FUNCTION
7	Busy	1 when ADC is converting
6	LHIGH	1 when Internal Temperature High Limit is exceeded
5	LLOW	1 when Internal Temperature Low Limit is exceeded
4	R1HIGH	1 when Remote 1 Temperature High Limit is exceeded
3	R1LOW	1 when Remote 1 Temperature Low Limit is exceeded
2	FAULT	1 when Remote 1 or Remote 2 is open circuit
1	R1THERM	1 when Remote 1 THERM Limit is exceeded
0	LTHERM	1 when Internal THERM Limit is exceeded

Bit 7 indicates that the ADC is busy converting a value. Bits 6 and 5 indicate that the internal temperature is above or below its high or low limits respectively. Likewise, bits 4 and 3 indicate that remote 1 temperature is above or below its limits. See [Section 4.13, "Limit Registers," on page 17](#) for detail on the limits are compared. Bit 2 indicates that an open circuit on one, or both, remote diode anode connections has been detected. See [Section 4.15, "Diode Fault Register"](#) for information on how to determine which diode has a fault. Bits 1 and 0 indicate that the remote 1 temperature or the internal temperature has exceeded their respective THERM limits. If bits 1 or 0 go high the $\overline{\text{ADDR/THERM}}$ signal will be asserted.

When the status register is read, bits 2 through 6 will individually clear provided that the error condition for that bit no longer exists. The $\overline{\text{ALERT/THERM2}}$ output is latched and will not be reset until the host has responded to the SMBALERT\# with an alert response address. The $\overline{\text{ALERT/THERM2}}$ signal will not reset if the status register has not been cleared.

4.10 Remote 2 Status Register

The Remote 2 Status register is a read only register that stores the operational status of the remote 2 temperature.

Table 4.5 Remote 2 Status Register

REMOTE 2 STATUS REGISTER		
BIT	NAME	FUNCTION
7-3		Reserved
2	R2HIGH	1 when Remote 2 Temperature High Limit is exceeded
1	R2LOW	1 when Remote 2 Temperature Low Limit is exceeded
0	R2THRM	1 when Remote 2 THERM limit is exceeded

Bits 2 and 1 indicate that the Remote 2 temperature is above or below its high or low limits. See [Section 4.13, "Limit Registers," on page 17](#) for detail on the limits are compared. Bit 0 indicates that the Remote 2 temperature has exceeded its THERM limit. If bit 0 goes high the $\overline{\text{ADDR/THERM}}$ signal will be asserted.

Bits 2 and 1 will be cleared individually when the status register is read provided that the error condition for that bit is gone.

4.11 Configuration Register

The configuration register controls the functionality of the temperature measurements.

Table 4.6 Configuration Register

CONFIGURATION REGISTER			
BIT	NAME	FUNCTION	DEFAULT
7	MASK1	0 = $\overline{\text{ALERT}}$ enabled 1 = ALERT disabled	0
6	RUN/STOP	0 = Active mode (continuously running) 1 = Standby mode	0
5	$\overline{\text{ALERT}}$ or $\overline{\text{THERM2}}$	0 = $\overline{\text{ALERT}}$ 1 = $\overline{\text{THERM2}}$	0
4 – 3	Reserved		0
2	Temperature Range Select	0 = 0°C to 127°C 1 = -64°C to 191°C	0
1	Reserved		0
0	APD	0 = Anti-Parallel Diode enabled 1 = Anti-Parallel Diode disabled	0

Bit 7 is used to mask the $\overline{\text{ALERT/THERM2}}$ output. When this bit is set to 0, any out of limit condition will assert $\overline{\text{ALERT/THERM2}}$. This bit is ignored if the $\overline{\text{ALERT/THERM2}}$ pin is configured as $\overline{\text{THERM2}}$ signal by bit 5.

Datasheet

Bit 6 initiates ADC conversions. When this bit is low, the ADC will convert temperatures in a continuous mode. When this bit is high, the ADC will be in standby mode, thus reducing supply current significantly though the SMBus will still be active. If bit 6 is 1 and the one-shot register is written to, the ADC will execute a temperature measurement and then return to standby mode.

Bit 5 sets the $\overline{\text{ALERT/THERM2}}$ pin to act as either an $\overline{\text{SMBALERT\#}}$ signal or as the $\overline{\text{THERM2}}$ signal. If bit 5 is set to 1 the $\overline{\text{ALERT/THERM2}}$ pin acts as the $\overline{\text{THERM2}}$ signal and bit 7 is ignored.

Bit 2 selects the range and format of the temperature as shown in [Table 4.1, "Temperature Data Format," on page 11](#)

Bit 0 enables the anti-parallel diode (remote 2 diode). If bit 0 is set to 0, the internal, remote 1 and remote 2 zones are active. This mode of operation is not compatible with substrate transistors such as those commonly used in CPUs. When bit 0 is set to 1, only the internal and remote 1 zones are active, and a substrate transistor may be used on remote 1.

4.12 Conversion Rate Register

The conversion rate register determines how many times the temperature value will be updated per second. The lowest 4 bits configure a programmable delay that waits between consecutive conversion cycles to obtain the desired conversion rate. [Table 4.7](#) shows the conversion rate and the associated quiescent current.

Table 4.7 Conversion Rates

CONVERSION RATE		
VALUE	CONVERSIONS/SECOND	TYPICAL QUIESCENT CURRENT (μA)
00h	0.0625	47
01h	0.125	TBD
02h	0.25	TBD
03h	0.5	TBD
04h	1	TBD
05h	2	TBD
06h	4	TBD
07h	8	TBD
08h	16	TBD
09h	32	TBD
0Ah	64	TBD
0Bh to FFh	Reserved	

4.13 Limit Registers

The EMC1033 compares the limit registers to the measured temperature. The data format of the programmed limits for this comparison is the same as the measurement data format determined by the Configuration Register. The user is required to update the limit registers to the new format when changing between measurement data formats.

The user can configure high and low temperature limits and an independent THERM limit. The temperature high limit (T_H) is an 11-bit value that is set by the Temperature High Limit High Byte register and the Temperature High Limit Low Byte register. The Temperature High Limit Low Byte register contains the three least significant bits as shown in [Table 4.2 on page 11](#).

The temperature low limit (T_L) is an 11-bit value that is set by the Temperature Low Limit High Byte register and the Temperature Low Limit Low Byte register as shown in [Table 4.2 on page 11](#).

The limits are automatically compared to the temperature measurement results (T_M) and have been exceeded if ($T_M \leq T_L$ or $T_M > T_H$). If either limit is exceeded then the appropriate bit is set high in the status register and the $\overline{\text{ALERT/THERM2}}$ output will respond as described in [Section 4.5 on page 12](#).

The THERM limit (T_{TH}) is a single byte value set by the THERM Limit register. Exceeding the THERM limit asserts the $\overline{\text{ADDR/THERM}}$ signal as described in [Section 4.6 on page 12](#). When the $\overline{\text{ALERT/THERM2}}$ pin is configured as $\overline{\text{THERM2}}$, then exceeding the high limit asserts this pin.

4.14 THERM Hysteresis Register

The THERM hysteresis register holds a hysteresis value that impacts the de-assertion of $\overline{\text{THERM}}$ as shown in [Figure 4.5 on page 13](#). It defaults to 10°C and can be set by the user at any time after power up. When the $\overline{\text{ALERT/THERM2}}$ pin is configured as $\overline{\text{THERM2}}$, then the output will not de-assert until the temperature drops below the Temperature High Limit minus the THERM Hysteresis value.

4.15 Diode Fault Register

The Diode Fault register holds the status of any diode faults that may have occurred as shown in [Table 4.8](#).

Table 4.8 Diode Fault Register

DIODE FAULT REGISTER			
BIT	NAME	FUNCTION	DEFAULT
1	EXFLT1	1 = Remote 1 is open circuit 0 = no fault	0
0	EXFLT2	1 = Remote 2 is open circuit 0 = no fault	0

4.16 One-Shot Register

Writing to the one-shot register while in standby mode initiates a conversion and comparison cycle. The EMC1033 will execute a temperature measurement, compare the data to the limit registers and return to the standby mode. A write to the one-shot register will be ignored if it occurs while the EMC1033 is in run mode.

4.17 Scratchpad Registers

The scratchpad registers may be used to verify communication via the SMBus. These registers do not have any affect on the operation of the device.

4.18 Ideality Factor Register

The ideality factor registers are used to program the remote diode ideality factor into the EMC1033 so that this error source can be eliminated. There are separate registers for both remote diodes so the ideality factor compensation for each diode is programmed independently. The default ideality factor is 1.008 and has a value of XX010010b or 12h.

Table 4.9 Diode Ideality Factor Values

DIODE IDEALITY FACTOR	VALUE	DIODE IDEALITY FACTOR	VALUE	DIODE IDEALITY FACTOR	VALUE	DIODE IDEALITY FACTOR	VALUE
0.9850	XX00 0000	1.0054	XX01 0000	1.0267	XX10 0000	1.0489	XX11 0000
0.9862	XX00 0001	1.0067	XX01 0001	1.0280	XX10 0001	1.0503	XX11 0001
0.9875	XX00 0010	1.0080	XX01 0010	1.0294	XX10 0010	1.0517	XX11 0010
0.9888	XX00 0011	1.0093	XX01 0011	1.0308	XX10 0011	1.0531	XX11 0011
0.9900	XX00 0100	1.0106	XX01 0100	1.0321	XX10 0100	1.0546	XX11 0100
0.9913	XX00 0101	1.0119	XX01 0101	1.0335	XX10 0101	1.0560	XX11 0101
0.9925	XX00 0110	1.0133	XX01 0110	1.0349	XX10 0110	1.0574	XX11 0110
0.9938	XX00 0111	1.0146	XX01 0111	1.0363	XX10 0111	1.0589	XX11 0111
0.9951	XX00 1000	1.0159	XX01 1000	1.0377	XX10 1000	1.0603	XX11 1000
0.9964	XX00 1001	1.0173	XX01 1001	1.0391	XX10 1001	1.0618	XX11 1001
0.9976	XX00 1010	1.0186	XX01 1010	1.0404	XX10 1010	1.0632	XX11 1010
0.9989	XX00 1011	1.0199	XX01 1011	1.0418	XX10 1011	1.0647	XX11 1011
1.0002	XX00 1100	1.0213	XX01 1100	1.0432	XX10 1100	1.0661	XX11 1100
1.0015	XX00 1101	1.0226	XX01 1101	1.0446	XX10 1101	1.0676	XX11 1101
1.0028	XX00 1110	1.0240	XX01 1110	1.0460	XX10 1110	1.0690	XX11 1110
1.0041	XX00 1111	1.0253	XX01 1111	1.0475	XX10 1111	1.0705	XX11 1111

4.19 Consecutive ALERT Register

Bit 7 of the Consecutive ALERT register enables the SMBus timeout feature when set to 1 (the default setting is 0). When enabled, the SMBus will timeout after approximately 25ms of inactivity. [Table 4.11](#) describes how bits 3-1 of the Consecutive ALERT register set how many consecutive error conditions must occur for each temperature measurement zone before the ALERT/THERM2 signal is asserted. These error conditions include diode faults and exceeding temperature limits. The default value is one which means that any out-of-limit measurement or any diode fault will cause the ALERT/THERM2 pin to be asserted. Any combination of bits 3-1 other than those shown will result in a value of one.

Table 4.10 Consecutive ALERT Register

BIT	NAME	FUNCTION	DEFAULT
7	SMBTE	0 = SMBus timeout disabled 1 = SMBus timeout enabled	0
6-4	Reserved		0
3-1	ALERTNUM	See Table 4.11	0
0	Reserved		0

Table 4.11 Consecutive ALERT Value

NUMBER OF EVENTS REQUIRED	VALUE		
	b3	b2	b1
1	0	0	0
2	0	0	1
3	0	1	1
4	1	1	1

Chapter 5 Application Information

This chapter provides information on maintaining accuracy when using diodes as remote sensors with SMSC Environmental Monitoring and Control devices. It is assumed that the users have some familiarity with hardware design and transistor characteristics.

SMSC supplies a family Environmental Monitoring and Control (EMC) devices that are capable of accurately measuring temperatures. Most devices include an internal temperature sensor along with the ability to measure one or more external sensors. The characteristics of an appropriate diode for use as the external sensor are listed in this chapter. Recommendations for the printed circuit board layout are provided to help reduce error caused by electrical noise or trace resistance.

5.1 Maintaining Accuracy

5.1.1 Physical Factors

Temperature measurement is performed by measuring the change in forward bias voltage of a diode when different currents are forced through the junction. The circuit board itself can impact the ability to accurately measure these small changes in voltage.

5.1.1.1 Layout

Apply the following guidelines when designing the printed circuit board:

1. Route the remote diode traces on the top layer.
2. Place a ground guard signal on both sides of the differential pair. This guard band should be connected to the ground plane at least every 0.25 inches.
3. Place a ground plane on the layer immediately below the diode traces.
4. Keep the diode traces as short as possible.
5. Keep the diode traces parallel, and the length of the two traces identical within 0.3 inches.
6. Use a trace width of 0.01 inches with a 0.01 inch guard band on each side.
7. Keep the diode traces away from sources of high frequency noise such as power supply filtering or high speed digital signals.
8. When the diode traces must cross high speed digital signals, make them cross at a 90 degree angle.
9. Avoid joints of copper to solder that can introduce thermocouple effects.

These recommendations are illustrated in [Figure 5.1 Routing the Diode Traces on page 21](#).

Figure 5.1 Routing the Diode Traces

5.1.1.2 Bypass Capacitors

Accurate temperature measurements require a clean, stable power supply. Locate a 0.1 μ F capacitor as close as possible to the power pin with a good ground. A low ESR capacitor (such as a 10 μ F ceramic) should be placed across the power source. Add additional power supply filtering in systems that have a noisy power supply.

A capacitor may be placed across the DP/DN pair at the remote sensor in noisy environments. Do not exceed a value of 2.2nF if this capacitor is installed.

5.1.1.3 Manufacturing

Circuit board assembly processes may leave a residue on the board. This residue can result in unexpected leakage currents that may introduce errors if the circuit board is not clean. For example, processes that use water-soluble soldering fluxes have been known to cause problems if the board is not kept clean.

5.1.1.4 Thermal Considerations

Keep the sensor in good thermal contact with the component to be measured. The temperature of the leads of a discrete diode will greatly impact the temperature of the diode junction. Make use of the printed circuit board to disperse any self-heating that may occur.

5.1.1.5 Remote Sensors Connected by Cables

When connecting remote diodes with a cable (instead of traces on the PCB) use shielded twisted pair cable. The shield should be attached to ground near the EMC1033, and should be left unconnected at the sensor end. Belden 8451 cable is a good choice for this application.

5.1.2 Sensor Characteristics

The characteristics of the diode junction used for temperature sensing will affect the accuracy of the measurement.

5.1.2.1 Selecting a Sensor

A diode connected small signal transistor is recommended. Silicon diodes are not a good choice for remote sensors. Small signal transistors such as the 2N3904 or the 2N3906 are recommended. Select a transistor with a constant value of h_{FE} in the range of 2.5 to 220 microamps. The magnitude of h_{FE} is not critical, because the variation in h_{FE} from one device to another cancels out of the temperature equations.

5.1.2.2 Compensating for Ideality of the diode

The remote diode may have an ideality factor based on the manufacturing process. Inaccuracy in the temperature measurement resulting from this ideality factor may be eliminated by configuring the ideality factor register. The EMC1033 is trimmed to an ideality factor of 1.008.

5.1.2.3 Circuit Connections

The more negative terminal for the remote temperature diode, DN, is internally biased with a forward diode voltage. Terminal DN is not referenced to ground. Remote temperature diodes can be constructed as shown in [Figure 5.2 Remote Temperature Diode Examples on page 23](#).

Datasheet

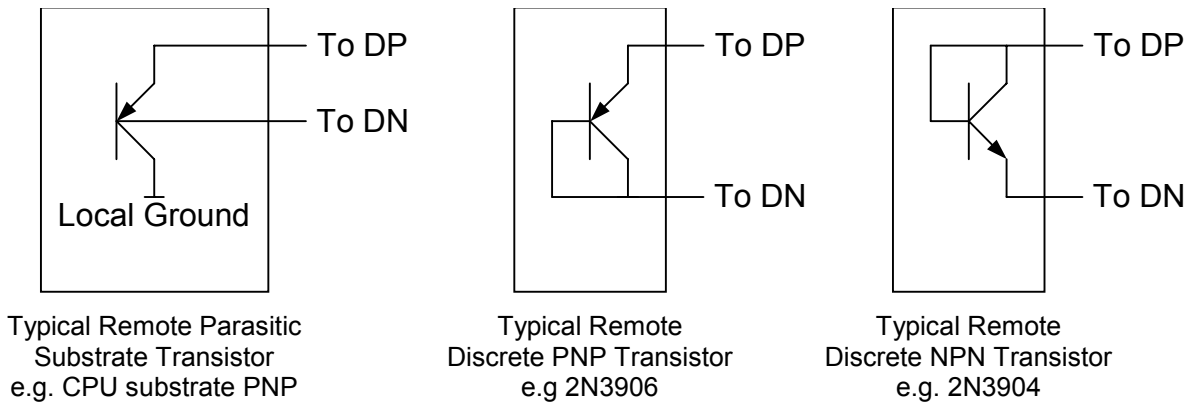

Figure 5.2 Remote Temperature Diode Examples

Environmental Monitoring and Control (EMC) devices supplied by SMSC are designed to make accurate temperature measurements. Careful design of the printed circuit board and proper selection of the remote sensing diode will help to maintain the accuracy.

Chapter 6 Package Outlines

Figure 6.1 8-Pin TSSOP Package Outline - 3x3mm Body 0.65mm Pitch

Table 6.1 8-Pin TSSOP Package Parameters

	MIN	NOMINAL	MAX	REMARKS
A	0.80	~	1.10	Overall Package Height
A1	0.05	~	0.15	Standoff
A2	0.75	0.85	0.95	Body Thickness
D	2.80	3.00	3.20	X Body Size
E	4.65	4.90	5.15	Y Span
E1	2.80	~	3.20	Y body Size
H	0.08	~	0.23	Lead Foot Thickness
L	0.40	~	0.80	Lead Foot Length
L1	0.95 REF			Lead Length
e	0.65 BSC			Lead Pitch
θ	0°	~	8°	Lead Foot Angle
W	0.22	~	0.38	Lead Width
ccc	~	~	0.10	Coplanarity

Notes:

1. Controlling Unit: millimeters.
2. Tolerance on the true position of the leads is ± 0.065 mm maximum.
3. Package body dimensions D and E1 do not include mold protrusion or flash. Dimensions D and E1 to be determined at datum plane H. Maximum mold protrusion or flash is 0.15mm (0.006 inches) per end, and 0.15mm (0.006 inches) per side.
4. Dimension for foot length L measured at the gauge plane 0.25 mm above the seating plane.
5. Details of pin 1 identifier are optional but must be located within the zone indicated.
