## 2K x 16 Reprogrammable State Machine PROM

### Features

- High speed: 100-MHz operation
  - $t_{CP} = 10 \text{ ns}$
  - $t_{CKO} = 8 \text{ ns}$
  - $t_{AS} = 2 \text{ ns}$
- 11-bit-wide state word
- Can be programmed as asynchronous PROM  $t_{AA} = 18 \text{ ns}$
- Optimum speed/power
- Individually bypassable input and output registers
- Individually programmable address/feedback muxes
- Synchronous and asynchronous chip select
- Synchronous and asynchronous INIT and programmable initialize word
- 16 outputs (CY7C259)
- Software support
- CY7C258 available in 28-pin, 300-mil plastic and ceramic DIP, LCC, PLCC
- CY7C259 available in 44-pin LCC and PLCC
- Reprogrammable in windowed packages
- Capable of withstanding greater than 2001V static discharge

### Functional Description

The CY7C258 and CY7C259 are 2K x 16 CMOS PROMs specifically designed for use in state machine applications.

State machines are one of the most common applications for registered PROMs. The CY7C258 and CY7C259 feature internal state feedback and a variety of programmable features to support 100-MHz state machines with as many as 2,048 distinct states.

It is easy to use a PROM as a state machine. Each array location contains output data as well as information fed back to select the next state. Note that a PROM is only limited by the number of array inputs. If a given state machine can be implemented in the number of inputs/feedbacks available (11 on the CY7C258/259), then it will always fit in the device. No software minimization is required.

Among the programmable features of the CY7C258/CY7C259 are individually bypassable input and output registers. The registers run off the same clock for pipeline capability. Each individual register can be programmed to capture data at the rising edge of the clock or to be transparent.

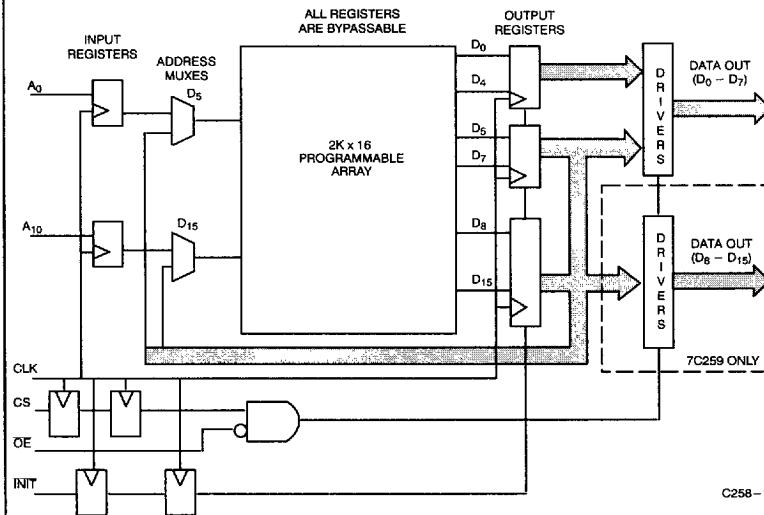

The registers at the inputs are useful for signals that require short set-up times ( $t_{AS} = 2 \text{ ns}$ ). The input register does introduce a cycle of latency, however. For signals that directly affect the next state of the machine, each input register can be bypassed. Note that the cycle time remains the same (10-ns min.), even if the inputs are bypassed.

Registers at the output are used to hold both state information and output data. These registers are also bypassable for maximum flexibility. Occasionally, an individual output cannot wait for the next clock edge. These outputs are sometimes called Mealy outputs, and can be created by bypassing the appropriate output register.

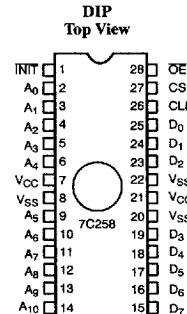

Since the CY7C258 and CY7C259 contain a 2K array, they each require 11 inputs. Each of these inputs can come from an input pin or from internal output register feedback. Eleven individually programmable address muxes allow the user to select the ratio of pin input and state feedback.

These devices have both an asynchronous output ( $OE$ ) and a synchronous chip select ( $CS$ ). The  $CS$  input is polarity programmable and registered twice. Each of

### Logic Block Diagram

### Functional Description (continued)

the CS registers can be bypassed in the same manner as the address input and output registers.

A separately controllable INIT input is included for user resets. If INIT is sampled LOW on the rising edge of CLK, the user programmable initialization word will appear at the outputs after the next CLK cycle. Each of the INIT registers can be bypassed in the same manner as the address input and output registers.

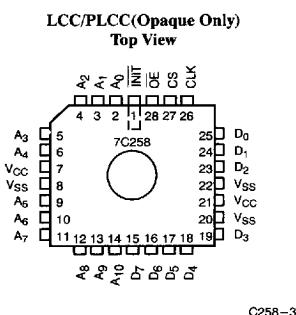

The difference between the CY7C258 and CY7C259 is in the packaging. The CY7C258 has three different types of outputs. D<sub>4</sub> – D<sub>0</sub> are dedicated outputs that do not feed back to the input muxes. D<sub>5</sub> – D<sub>7</sub> appear on the output pins and are fed back to the input muxes. Finally, D<sub>8</sub> – D<sub>15</sub> are dedicated feedback lines that do not appear at the output pins. The dedicated feedback allows the CY7C258 to be packaged in 28-pin packages. The CY7C258 is available in 28-pin LCC, PLCC, and slim 300-mil DIP packages.

On the CY7C259, all 16 array outputs are available at the pins. Outputs D<sub>4</sub> – D<sub>0</sub> remain as dedicated outputs while D<sub>5</sub> – D<sub>15</sub> appear at the pins and are also fed back to the input muxes. This organization allows the user maximum flexibility in selecting the ratio of outputs to state feedback. The availability of state information at pins also improves testability. The CY7C259 is packaged in 44-pin LCC and PLCC packages.

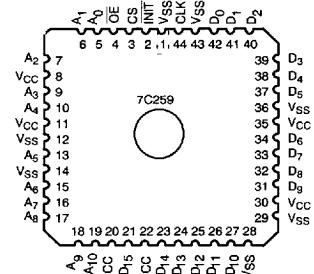

Several third-party programmers feature support for PROMs as state machines, including Data I/O (ABEL), ISDATA (LOG/iC), and CUPL. The devices are also supported on the Cypress Warp2 and Warp3 development software.

The CY7C258 and CY7C259 offer the advantage of low power, superior performance, and programming yield. The EPROM cells allow for each memory location to be 100% tested, with each location being written into, erased, and repeatedly exercised prior to encapsulation. Each PROM is also tested for AC performance to guarantee that the product will meet DC and AC specification limits after customer programming.

## Notes:

2. Contact a Cypress representative for industrial temperature range specification.
3. T<sub>A</sub> is the "instant on" case temperature.
4. See the last page of this specification for Group A subgroup testing information.
5. See Introduction to CMOS PROMs in this Data Book for general information on testing.
6. For test purposes, not more than one output at a time should be shorted. Short circuit test duration should not exceed 30 seconds.
7. Add  $1\text{ mA/MHz}$  for AC power component.
