

POWER MANAGEMENT

Features

- V_{IN} Range: 2.9 – 5.5V
- V_{OUT} Selectable: 0.8 - 3.3V
- Up to 1.8A Output Current for Each Channel
- Ultra-Small Footprint, <1mm Height Solution
- 2.5MHz Switching Frequency
- Efficiency Up to 93%
- Low Output Noise Across Load Range
- Excellent Transient Response
- Start Up into Pre-Bias Output
- 100% Duty-Cycle Low Dropout Operation
- <1 μ A Shutdown Current
- Internal Soft Start
- Input Under-Voltage Lockout
- Output Over-Voltage, Current Limit Protection
- Over-Temperature Protection
- Adjustable Output Voltage
- 2mm x 3mm x 0.8mm thermally enhanced MLPQ-W18 package
- -40 to +85°C Temperature Range
- Pb-Free product. RoHS/WEEE and Halogen Free compliant

Applications

- Desktop Computing
- Set-Top Box
- LCD TV
- Network Cards
- Printer

Typical Application Circuit

Description

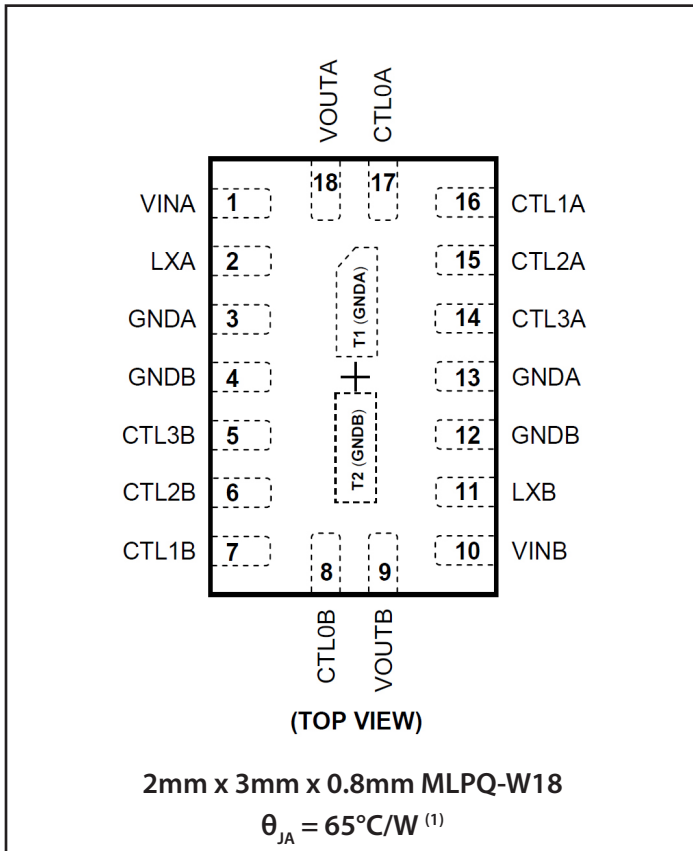

The SC283 is a dual channel 1.8A synchronous step-down regulator designed to operate with an input voltage range of 2.9 to 5.5 Volts. Each channel offers fifteen pre-determined output voltages via four control pins programmable from 0.8 to 3.3 Volts. The control pins allow for on-the-fly voltage changes, enabling system designers to implement dynamic power savings. The SC283 is also capable of adjusting the output voltage via an external resistor divider.

The device operates with a fixed 2.5MHz oscillator frequency, allowing the use of small surface mount external components.

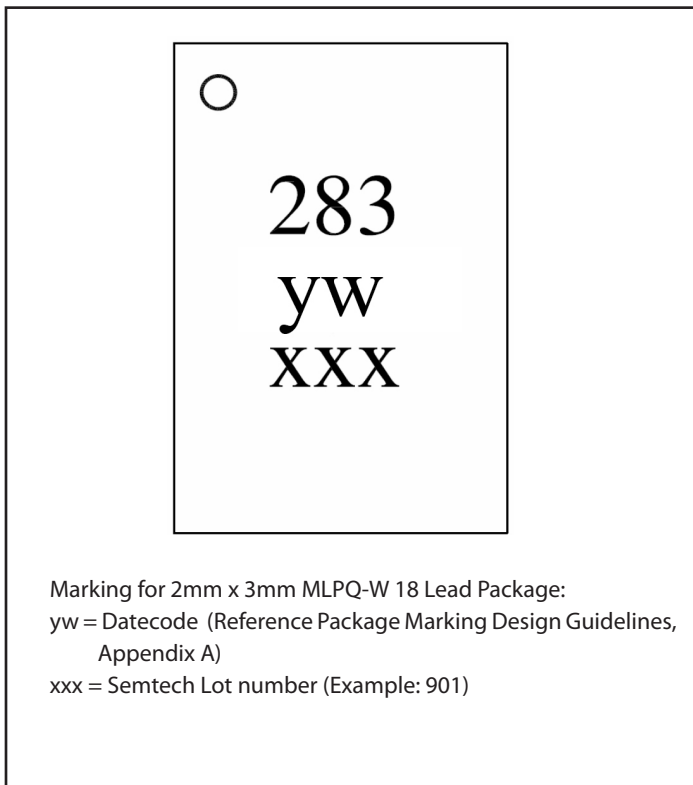

Connecting CTL0 — CTL3 to logic low forces the device into shutdown mode reducing the supply current to less than 1 μ A. Connecting any of the control pins to logic high enables the converter and sets the output voltage according to Table 1. Other features include under-voltage lockout, soft-start to limit inrush current, and over-temperature protection.

The SC283 is available in a thermally-enhanced, 2mm x 3mm x 0.8mm MLPQ-W18 package and has a rated temperature range of -40 to +85°C.

Pin Descriptions

Pin #	Pin Name	Pin Function
1	VINA	Channel A. Input supply voltage for the converter power stage and internal circuitry.
2	LXA	Switching node of Channel A - connect an inductor between this pin and the output capacitor.
3, 13, T1	GNDA	Channel A. Ground connection for converter power stage and internal circuitry.
4, 12, T2	GNDB	Channel B. Ground connection for converter power stage and internal circuitry.
5	CTL3B	Channel B. Control bit 3 - see Table 1 for decoding. This pin has a 1 M Ω internal pulldown resistor. This resistor is switched in circuit whenever the pin voltage is below the input high threshold, or when the part is in undervoltage lockout.
6	CTL2B	Channel B. Control bit 2 - see Table 1 for decoding. This pin has a 1 M Ω internal pulldown resistor. This resistor is switched in circuit whenever the pin voltage is below the input high threshold, or when the part is in undervoltage lockout.
7	CTL1B	Channel B. Control bit 1 - see Table 1 for decoding. This pin has a 1 M Ω internal pulldown resistor. This resistor is switched in circuit whenever the pin voltage is below the input high threshold, or when the part is in undervoltage lockout.
8	CTL0B	Channel B. Control bit 0 - see Table 1 for decoding. This pin has a 1 M Ω internal pulldown resistor. This resistor is switched in circuit whenever the pin voltage is below the input high threshold, or when the part is in undervoltage lockout.
9	VOUSB	Output voltage sense pin of Channel B.
10	VINB	Channel B. Input supply voltage for the converter power stage and internal circuitry.
11	LXB	Switching node of Channel B - connect an inductor between this pin and the output capacitor.
14	CTL3A	Channel A. Control bit 3 - see Table 1 for decoding. This pin has a 1 M Ω internal pulldown resistor. This resistor is switched in circuit whenever the pin voltage is below the input high threshold, or when the part is in undervoltage lockout.
15	CTL2A	Channel A. Control bit 2 - see Table 1 for decoding. This pin has a 1 M Ω internal pulldown resistor. This resistor is switched in circuit whenever the pin voltage is below the input high threshold, or when the part is in undervoltage lockout.
16	CTL1A	Channel A. Control bit 1 - see Table 1 for decoding. This pin has a 1 M Ω internal pulldown resistor. This resistor is switched in circuit whenever the pin voltage is below the input high threshold, or when the part is in undervoltage lockout.
17	CTL0A	Channel A. Control bit 0 - see Table 1 for decoding. This pin has a 1 M Ω internal pulldown resistor. This resistor is switched in circuit whenever the pin voltage is below the input high threshold, or when the part is in undervoltage lockout.
18	VOUSA	Output voltage sense pin of Channel A.

Block Diagram

Applications Information

Detailed Description

The SC283 is a two channel synchronous step-down converter. Both channels on this device are designed to operate in fixed-frequency PWM mode at 2.5MHz and provide the same current capacity of up to 1.8A. The switching frequency is chosen to minimize the size of the external inductor and capacitors while maintaining high efficiency. Both channels of SC283 are independent.

Operation

During normal operation, the PMOS MOSFET is activated on each rising edge of the internal oscillator. The voltage feedback loop uses an internal feedback resistor divider. The period is set by the internal oscillator. The device has an internal synchronous NMOS rectifier and does not require a Schottky diode on the LX pin. The device operates as a buck converter in PWM mode with a fixed frequency of 2.5MHz.

Programmable Output Voltage

Both channels on SC283 have fifteen pre-determined output voltage values which can be individually selected by programming the CTL input pins (see Table 1 — Output Voltage Settings). Each CTL pin has an active 1 MΩ internal pulldown resistor. The 1MΩ resistor is switched in circuit whenever the CTL input voltage is below the input threshold, or when the part is in undervoltage lockout. It is recommended to tie all high CTL pins together and use an external pull-up resistor to VIN if there is no enable signal, or if the enable input is an open drain/collector signal. The CTL pins may be driven by a microprocessor to allow dynamic voltage adjustment for systems that reduce the supply voltage when entering sleep states. Avoid all zeros being present on the CTL pins when changing programmable output voltages as this would disable the device.

SC283 is also capable of regulating a different (higher) output voltage, which is not shown in the Table 1, via an external resistor divider. There will be a typical 2μA current flowing into the VOUT pin. The typical schematic for an adjustable output voltage option from the standard 1.0V with CTLx=[0010], is shown in Figure 1. RFB1 and RFB2 are used to adjust the desired output voltage. If the RFB2 current is such that the 2μA VOUT pin current can be ignored, then RFB1 can be found by Equation 1. RFB2 needs to be low

enough in value for the current through the resistor chain to be at least 20μA in order to ignore the VOUT pin current.

$$R_{FB1} = \frac{V_{OUT} - V_{OSTD}}{V_{OSTD}} \cdot R_{FB2} \quad (1)$$

where V_{OSTD} is the pre-determined output voltage via the CTL pins.

C_{FF} is needed to maintain good transient response performance. The correct value of C_{FF} can be found using Equation 2.

$$C_{FF} [nF] = 2.5 \times \frac{(V_{OUT} - 0.5)^2}{R_{FB1} [k\Omega] \cdot (V_{OUT} - V_{OSTD})} \times \left(\frac{V_{OSTD}}{V_{OSTD} - 0.5} \right) \quad (2)$$

To simplify the design, it is recommended to program the desired output voltage from a standard 1.0V as shown in Figure 1 with the correct C_{FF} calculated from Equation 2. For programming the output voltage from other standard voltages, R_{FB1} , R_{FB2} and C_{FF} need to be adjusted to meet Equations 1 and 2.

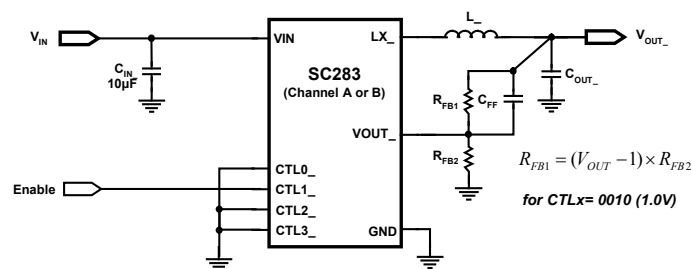

Figure 1 — Typical Schematic for Adjusting the Output Voltage Up from an Output Voltage of 1.0V (CTLx=[0010])

Maximum Power Dissipation

Each channel of SC283 has its own Θ_{JA} of 65°C/W when only one channel is in operation. Since both channels are within same package, there is about 50% heat which will be transferred to the adjacent channel. The equivalent total thermal impedance will be higher when the neighboring channel is also in operation. To guarantee an operating junction temperature of less than 125°C, Figure 2 shows the maximum allowable power loss of each channel. The curve is based upon the junction temperature of either channel reaching a maximum of 125°C. Each channel of SC283 can support up to 1.8A load current. Figures 3a

Applications Information (continued)

and 3b show the maximum allowable load current based upon the limit of maximum loss for $V_{IN}=3.3V$ and $V_{IN}=5.0V$, respectively. The curves are drawn for high duty-cycle operation. If the operating duty-cycle is lower, the loss is lower allowing higher load current.

Figure 2 — Maximum allowable loss for each channel for a maximum junction temperature of 125°C

Protection Features

The SC283 provides the following protection features:

- Current Limit
- Over-Voltage Protection
- Soft-Start Operation
- Thermal Shutdown

Current Limit and Protection

The internal PMOS power device in the switching stage is protected by a current limit feature. If the inductor current is above the PMOS current limit for 16 consecutive cycles, the part enters foldback current limit mode and the output current is limited to the current limit holding current (I_{CL_HOLD}) of a few hundred milliamperes. Under this condition, the output voltage will be the product of I_{CL_HOLD} and the load resistance. The current limit holding current will decrease when the output voltage increases. The load presented must fall below the current limit holding current for the part to exit foldback current limit mode. Figure 4 shows how the typical current limit holding current varies with output voltage. The SC283 is capable of sustaining an indefinite short circuit without damage and will resume normal operation when the fault is removed. The foldback current limit mode is disabled during soft-start. Current limit functionality is shown in Figure 6.

Figure 3 — Maximum allowable Load Current for each channel for a maximum junction temperature of 125°C

Figure 4 — Typical Current Limit Holding Current

Applications Information (continued)

vs. Output Voltage

Over-Voltage Protection

In the event of a 15% over-voltage on the output, the PWM drive is disabled leaving the LX pin floating.

Soft-Start

The soft-start mode is activated after VIN reaches its UVLO and one or more CTL pins are set high to enable the part. A thermal shutdown event will also activate the soft start sequence. Soft-start mode controls the maximum current during startup thus limiting inrush current. The PMOS current limit is stepped through four soft start levels of approximately 20%, 25%, 40%, & 100%. Each step is maintained for 200µs following an internal reference start up duration of 50µs giving a total nominal startup period of 850µs. During startup, the chip operates by controlling the inductor current swings between 0A and current limit. If at any time V_{OUT} reaches 86% of the target or at the end of the soft-start period, the SC283 will switch to PWM mode operation. Figure 5 shows the typical diagram of soft start operation.

The SC283 is capable of starting up into a pre-biased output. When the output is precharged by another supply rail, the SC283 will not discharge the output during the soft start interval.

Shut Down

When all CTL pins of each channel are low, the channel will run in shutdown mode, drawing less than 1µA from the input power supply. The internal switches and bandgap voltage will be immediately turned off.

Thermal Shutdown

The device has a thermal shutdown feature to protect the SC283 if the junction temperature exceeds 160°C. During thermal shutdown, the on-chip power devices are disabled, tri-stating the LX output. When the temperature drops by 10°C, it will initiate a soft start cycle to resume normal operation.

Inductor Selection

The SC283 converter has internal loop compensation. The compensation is designed to work with an output filter corner frequency of less than 40kHz for a V_{IN} of 5V and 50kHz for a V_{IN} of 3.3V over any operating condition. The

corner frequency of the output filter is shown in Equation 3.

$$f_c = \frac{1}{2\pi\sqrt{L \cdot C_{OUT}}} \quad (3)$$

Values outside this range may lead to instability, malfunction, or out-of-specification performance.

In general, the inductance is chosen by making the inductor ripple current to be less than 30% of maximum load current. When choosing an inductor, it is important to consider the change in inductance with DC bias current. The inductor saturation current is specified as the current at which the inductance drops a specific percentage from the nominal value. This is approximately 30%. Except for short-circuit or other fault conditions, the peak current must always be less than the saturation current specified by the manufacturer. The peak current is the maximum load current plus one half of the inductor ripple current at the maximum input voltage. Load and/or line transients can cause the peak current to exceed this level for short durations. Maintaining the peak current below the inductor saturation specification keeps the inductor ripple current and the output voltage ripple at acceptable levels. Manufacturers often provide graphs of actual inductance and saturation characteristics versus applied inductor current. The saturation characteristics of the inductor can vary significantly with core temperature. Core and ambient temperatures should be considered when examining the core saturation characteristics.

When the inductance has been determined, the DC resistance (DCR) must be examined. The efficiency that can be achieved is dependent on the DCR of the inductor. The lower values give higher efficiency. The RMS DC current rating of the inductor is associated with losses in the copper windings and the resulting temperature rise of the inductor. This is usually specified as the current which produces a 40°C temperature rise. Most copper windings are rated to accommodate this temperature rise above maximum ambient.

Magnetic fields associated with the output inductor can interfere with nearby circuitry. This can be minimized by the use of low noise shielded inductors which use the

Applications Information (continued)

minimum gap possible to limit the distance that magnetic fields can radiate from the inductor. However shielded inductors typically have a higher DCR and are thus less efficient than a similarly sized non-shielded inductor.

Final inductor selection depends on various design considerations such as efficiency, EMI, size, and cost. Table 2 lists the manufacturers of recommended inductor options. The saturation characteristics and DC current ratings are also shown.

Manufacturer Part Number	L (μH)	DCR Max (Ω)	Rated Current (A)	L at Rated Current (μH)	Dimensions LxWxH (mm)
TOKO 1071AS-2R2M	2.20±20%	0.060	1.80	1.54	2.8x3.0x1.5

Table 2 – Recommended Inductors

C_{OUT} Selection

The internal voltage loop compensation in the SC283 limits the minimum output capacitor value to 22μF if using a 2.2μH inductor or 44μF if using a 1μH inductor. This is due to its influence on the the loop crossover frequency, phase margin, and gain margin. Increasing the output capacitor above this minimum value will reduce the crossover frequency and provide greater phase margin. The total output capacitance should not exceed 50μF to avoid any start-up problems. For most typical applications it is recommended to use an output capacitance of 22μF to 44μF. When choosing the output capacitor's capacitance, verify the voltage derating effect from the capacitor vendor's data sheet.

Capacitors with X7R or X5R ceramic dielectric are recommended for their low ESR and superior temperature and voltage characteristics. Y5V capacitors should not be used as their temperature coefficients make them unsuitable for this application.

The output voltage droop due to a load transient is deter-

mined by the capacitance of the ceramic output capacitor. The ceramic capacitor supplies the load current initially until the loop responds. Within a few switching cycles the loop will respond and the inductor current will increase to match the required load. The output voltage droop during the period prior to the loop responding can be related to the choice of output capacitor by the relationship from Equation 4.

$$C_{OUT} = \frac{3 \cdot \Delta I_{LOAD}}{V_{DROOP} \cdot f_{OSC}} \quad (4)$$

The output capacitor RMS ripple current may be calculated from Equation 5.

$$I_{COUT(RMS)} = \frac{1}{2\sqrt{3}} \left(\frac{V_{OUT} \cdot (V_{IN(MAX)} - V_{OUT})}{L \cdot f_{OSC} \cdot V_{IN}} \right) \quad (5)$$

Table 3 lists the manufacturers of recommended output capacitor options.

Manufacturer Part Number	Value (μF)	Type	Rated Voltage (VDC)	Value at 3.3V (μF)	Dimensions LxWxH (mm)
Murata GRM21BR60J106K	10±10%	X5R	6.3	4.74	2.0x1.25x1.25 (EIA:0805)

Murata GRM31CR60J476M	47±20%	X5R	6.3	20.3	3.2x1.6x1.6 (EIA:1206)

Table 3 – Recommended Capacitors

C_{IN} Selection

The SC283 source input current is a DC supply current with a triangular ripple imposed on it. To prevent large input voltage ripple, a low ESR ceramic capacitor is required. A minimum value of 10μF should be used. It is important to consider the DC voltage coefficient characteristics when determining the actual required value. It should be noted a 10μF, 6.3V, X5R ceramic capacitor with 5V DC applied may exhibit a capacitance as low as 4.5μF.

Applications Information (continued)

To estimate the required input capacitor, determine the acceptable input ripple voltage and calculate the minimum value required for C_{IN} from Equation 6.

$$C_{IN} = \frac{\frac{V_{OUT}}{V_{IN}} \left(1 - \frac{V_{OUT}}{V_{IN}} \right)}{\left(\frac{\Delta V}{I_{OUT}} - ESR \right) \cdot f_{OSC}} \quad \text{..... (6)}$$

The input capacitor RMS ripple current varies with the input and output voltage. The maximum input capacitor RMS current is found from Equation 7.

$$I_{CIN(RMS)} = \sqrt{\frac{V_{OUT}}{V_{IN}} \left(1 - \frac{V_{OUT}}{V_{IN}} \right)} \quad \text{..... (7)}$$

The input voltage ripple and RMS current ripple are at a maximum when the input voltage is twice the output voltage or 50% duty cycle.

The input capacitor provides a low impedance loop for the edges of pulsed current drawn by the PMOS switch. Low ESR/ESL X5R ceramic capacitors are recommended for this function. To minimise stray inductance, the capacitor should be placed as closely as possible to the VIN and GND pins of the SC283.

Applications Information (continued)

PCB Layout Considerations

The layout diagram in Figure 7 shows a recommended top-layer PCB for the SC283 and supporting components. Figure 8 shows the bottom layer for this PCB. Fundamental layout rules must be followed since the layout is critical for achieving the performance specified in the Electrical Characteristics table. Poor layout can degrade the performance of the DC-DC converter and can contribute to EMI problems, ground bounce, and resistive voltage losses. Poor regulation and instability can result.

The following guidelines are recommended when developing a PCB layout:

1. The input capacitor, C_{IN} , should be placed as close to the VIN and GND pins as possible. This capacitor provides a low impedance loop for the pulsed currents present at the buck converter's input. Use short wide traces to connect as closely to the IC as possible. This will minimize EMI and input voltage ripple by localizing the high frequency current pulses.
2. Keep the LX pin traces as short as possible to minimize pickup of high frequency switching edges to other parts of the circuit. C_{OUT} and L should be connected as close as possible between the LX and GND pins, with a direct return to the GND pin from C_{OUT} .
3. Route the output voltage feedback/sense path away from the inductor and LX node to minimize noise and magnetic interference.
4. Use a ground plane referenced to the SC283 GND pin. Use several vias to connect to the component side ground to further reduce noise and interference on sensitive circuit nodes.
5. If possible, minimize the resistance from the output and GND pin to the load. This will reduce the voltage drop on the ground plane and improve the load regulation. It will also improve the overall efficiency by reducing the copper losses on the output and ground planes.
