

VL86C310

RISC VIDEO CONTROLLER (VIDC)

FEATURES

- Pixel rate selectable as 8, 12, 16, or 24 MHz
- Serializes data to 1-, 2-, 4-, or 8- bits per pixel
- 16 x 13-bit words - 4096 color lookup palette
- Three 4-bit DACs (one for each CRT gun)
- Fully programmable screen parameters
- Screen border in any of the 4096 possible colors
- Flexible cursor sprite
- Support for interlaced display format
- External synchronization capability
- Very high resolution monochrome mode support
- High quality stereo sound generation

DESCRIPTION

The Video Controller (VIDC) accepts video data from DRAM under DMA control, serializes and passes it through a color look-up palette, and converts it to analog signals for driving the CRT guns. The chip also controls all the display timing parameters plus the position and pattern of the cursor sprite. In addition, the VIDC includes an exponential DAC and stereo image table for the generation of high quality sound from data in the DRAM.

The VIDC requests data from the RAM when required, and buffers it in one of three first-in, first-out memories (FIFOs). Note that the addressing of the data in RAM is controlled elsewhere in the system (usually in the VL86C110 Memory Controller, MEMC). Data is requested in blocks of four 32-bit words, allowing efficient use of page-mode DRAM without locking up the system data bus for long periods.

The VIDC is a highly programmable device, offering a very wide choice of display formats. The pixel rate can be se-

lected in a range between 8 and 24 MHz and the data can be serialized to either 8-, 4-, 2-, or 1-bit per pixel. The horizontal timing parameters can be controlled to units of 2 pixels, and the vertical timing parameters can be controlled in units of a raster. The color lookup palette which drives the three on-chip DACs is 13-bits wide, offering a choice from 4096 colors or an external video source.

Extensive use is made of pipelining throughout the device.

The cursor sprite is 32 pixels wide, and any number of rasters high. Three simultaneous colors (from the 4096 possible) are supported, and any pixel can be defined as transparent, making possible cursors of many shapes. The cursor can be positioned anywhere on the screen.

The sound system implemented on the device can support up to eight channels, each with a separate stereo position.

BLOCK DIAGRAM

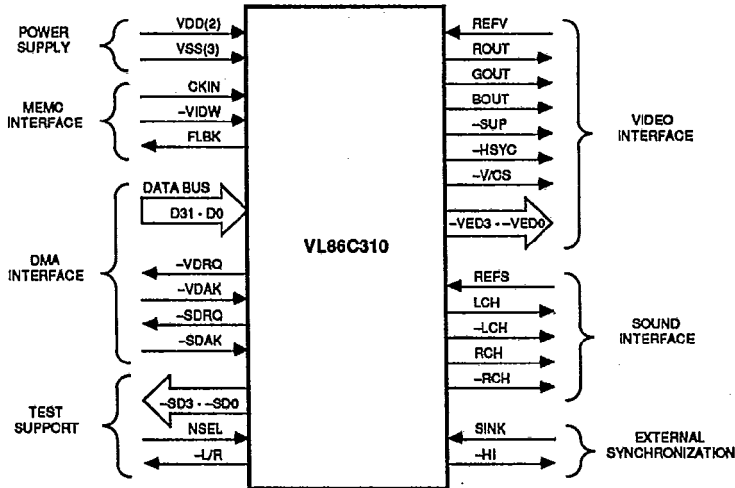

**SIGNAL DESCRIPTIONS**

Signal Name	Pin Number	Signal Description
CKIN	19	Clock In (TTL level input); Master 24 MHz system clock input - Usually this is the same signal as the VL86C110 Memory Controller (MEMC) uses to generate system timing. Since VIDC resynchronizes all its inputs to this clock reference, these two clocks are not required to be the same frequency, allowing the display frequency to be independent of the processor.
-VIDW	27	Register Write Strobe (TTL level input) - An active low on this line writes data into one of the VIDC registers. The address of the register is supplied on the upper bits, and the data to be written on the lower bits of the data bus. Normally, this signal is generated by MEMC as it is the device that decodes the memory address map in the system.
D31-D0	7-1, 68-44	Data Bus (TTL level inputs) - This 32-bit bus carries data for register writes, video DMA, cursor DMA, and sound DMA, according to which type of data strobe is present.
-VDRQ	23	Video Data Request (CMOS level output) - This signal is driven active (low) when the VIDC requires another block of 16 bytes of video data (when -HSYC is high) or cursor data (when -HSYC is low). It is driven high again by the first valid video data acknowledge, -VDAK.
-VDAK	8	Video Data Acknowledge (TTL level input) - An active low on this signal strobes a data word into the video or cursor FIFO depending on the state of HSYNC when the request was made. Note that a low on -VDRQ signifies a request for four words of data, and so -VDAK must go low four times to service each request.
-SDRQ	24	Sound Data Request (CMOS level output) - This signal is driven low when the VIDC requires another block of 16 bytes of sound data. It is driven high again by the first valid -SDAK.
-SDAK	9	Sound Data Acknowledge (TTL level input) - An active low on this signal strobes a data word into the sound FIFO. Note that a low on -SDRQ signifies a request for four words of data, and so -SDAK must go low four times to service each request.
FLBK	22	Vertical Flyback (CMOS level output) - This signal is driven high when the display is in vertical flyback (retrace). Specifically, it is set high at the start of the first raster which is not display data, although this may be border, (at the bottom of the screen), and is cleared down at the start of the first raster which is display data (at the top of the screen).
SINK	20	External Synchronization pulse (TTL level input) - A high on this signal resets the vertical timing counter, and if interlaced display format is being used, the odd field is selected. The horizontal timing counter, and all other registers are unaffected by this signal.
-HI	21	Horizontal Interlace Marker (Test pin - CMOS level output) - When an interlaced display format is selected this signal is driven low half way along the raster and stays low until the end of each raster. If non-interlaced displays are used, this pin may be used as a programmable timer on each raster.
-SD3 --SD0	34-37	Multiplexed Sound Data (Test pins - CMOS level outputs) - These pins are used for testing the digital data paths through the chip. Normally, depending on the state of NSEL, they output the inverse of one of the two nibbles of the data byte being fed to the sound DAC, but in test mode three, they output the inverse of the data being fed to the green or blue DACs, again depending on the state of NSEL. For more information on test mode three, refer to the control register section.
NSEL	33	Sound Data Output Selector (Test pin - TTL level input) - When this signal is low, the sound data bus port outputs the low nibble of the sound data, or the green DAC data. When NSEL is high, the sound data bus port outputs the high nibble of the sound data, or the blue DAC data.
-L/R	17	Left/Right (Test pin - TTL level output) - This signal is driven low when the sound output is steered to the left output port, and is high when the sound output is steered to the right output port. In test mode three, the pin changes its function, and outputs the sound sampling clock instead.
REFV	43	Video DAC Reference Current (Analog input) - A current must be fed into this pin to set the output current of the video DACs. The full scale output current is 15 times this current. In most applications a resistor from VDD to this pin is sufficient to set the current.

SIGNAL DESCRIPTIONS (Cont.)

Signal Name	Pin Number	Signal Description
ROUT	39	Red Analog output (Analog output) - The output to the CRT guns is in the form of a current sink. Maximum brightness is defined as 15 times the reference current, and "black" is defined as zero current. Level shifting and buffering is normally required to drive the CRT inputs.
GOUT	40	Green Analog output (Analog output) - Same description as for ROUT.
BOUT	41	Blue Analog output (Analog output) - Same description as for ROUT.
-SUP	28	Supremacy output signal (CMOS level output) - This signal is used to control a multiplexer between the output of VIDC and an external source when video mixing is required. If bit 12 of the video or cursor palette for any logical color is set, -SUP is driven low when that logical color is displayed. In this way any logical color can be defined as being supreme or not, on a pixel-by-pixel basis.
-HSYC	25	Horizontal Synchronization pulse (CMOS level output) - This signal is required by some monitors. It is also used by the MEMC to discriminate between cursor and video data requests. The pulse is active low, and the pulse width is programmable in units of two pixels, though there are certain system-related restrictions. See section Restrictions On Parameters.
-VICS	26	Vertical/Composite Synchronization pulse (CMOS level output) - Depending on bit seven in the control register, this pin can be either the vertical sync pulse, or a form of composite sync pulse. The vertical sync pulse width is programmable in units of a raster and, if selected, is active low. The composite sync pulse is the XNOR of -HSYC and -VSYC.
-VED0		
-VED3 -	39-32	Video External Data output (CMOS level output) - The inverse of the four bits of data which are fed to the red DAC are output on these pins. With an external serializer, this data can be used to produce very high resolution monochrome displays.
REFS	12	Sound DAC Reference Current (Analog input) - A current must be fed into this pin to set the output current of the sound DAC. The full scale output current is approximately 32 times this current. In most applications, a resistor from VDD to this pin is sufficient to set the current.
LCH	13	Left Channel Positive Sound output (Analog output) - The sound output is the form of a current sink which is switched to one of four pins (pins 13-16). The left channel signal is produced by externally integrating and subtracting the two signals, LCH and -LCH. Similarly, the right channel signal is produced by externally integrating and subtracting the two signals RCH and -RCH.
-LCH	14	Left Channel Negative Sound output (Analog output) - See description of LCH.
RCH	15	Right Channel Positive Sound output (Analog output) - See description of LCH.
-RCH	16	Right Channel Negative Sound output (Analog output) - See description of LCH.
VSSD	18	Power (Digital ground) - This pin is the ground supply to the digital circuits in the device.
VSSS	10	Power (Sound ground) - This pin is the ground supply to the sound DAC in the device. It must be connected to the pin VSSD outside the chip.
VSSV	42	Power (Video ground) - This pin is the ground supply to the video DACs in the device. It must be connected to the pin VSSD outside the chip.
VDDD	38	Power (Digital +5 V $\pm 5\%$ supply) - This pin is the positive supply to the digital circuits in the device.
VDDS	11	Power (Sound +5 V $\pm 5\%$ supply) - This pin is the positive supply to the sound DAC in the device. It must be at the same potential as VDDD, and should be decoupled to VSSS. Note that the sound reference current input and the sound analog output currents are all referenced to this signal.

FUNCTIONAL PIN DIAGRAM

FUNCTIONAL DESCRIPTION

Apart from the three 32-bit wide FIFOs (video, cursor, and sound), the VIDC contains 46 write-only registers of up to 13-bits each. In all cases the address of the register is contained in the top 6-bits (31-26) of the data field. Bits 25 and 24 are not used. The actual data bits are distributed among the remaining 24-bits of the data field according to the register in question. The encoding format is shown in Figure 1.

Treating bit 24 as the least significant address bit, the register map is shown in Table 1 on the following page. Note that there are 18 undefined locations. These

locations should never be written to as they may actually contain other registers. (Some registers are dual-mapped within the device.)

In order to define the display format, eleven registers must be programmed. Screen parameter definitions are shown in Figure 2 on the following page.

Video Palette Logical Colors 0-FH: Addresses 00-3CH

In 1-, 2-, and 4-bits per pixel mode, data bits D12-D0 define the physical color corresponding to that logical color. The data bus encoding is shown in Figure 3. Figure 4 shows the physical color field specification.

- D3-D0 define the red amplitude (D0 least significant)
- D7-D4 define the green amplitude (D4 least significant)
- D11-D8 define blue amplitude (D8 least significant)
- D12 defines the supremacy bit for that color

5

In 8-bits per pixel mode, only 9-bits are defined as shown in Figure 5. The palette outputs define the least significant bits of each color. The most significant bits for each color now come directly from the upper 4-bits of the logical color field, giving the physical data field as shown in Figure 6.

In four and 8-bits per pixel mode, all 16 locations should be programmed. In 2-bits per pixel mode only colors zero, one, two, and three need to be defined. In 1-bit per pixel mode, only colors zero and one need to be programmed.

Border Color Register: Address 40H

In all modes, this register defines the border physical color. The data bus encoding is shown in Figure 7.

- D3-D0 define the red amplitude (D0 least significant)
- D7-D4 define the green amplitude (D4 least significant)
- D11-D8 define the blue amplitude (D8 least significant)
- D12 defines the supremacy bit for the border

FIGURE 14. HORIZONTAL DISPLAY END REGISTER DATA BUS ENCODING

FIGURE 15. HORIZONTAL BORDER END REGISTER DATA BUS ENCODING

FIGURE 16. HORIZONTAL CURSOR START REGISTER DATA BUS ENCODING

Horizontal Border End Register (HBER): Address 94H

This register defines the time, in units of two-pixel periods, from the start of -HSYC pulse to the end of the border display (i.e., the first pixel which is not border). If M pixels are required in this time, then value (M-1)/2 should be programmed into the HBER. [M must be odd.] Again, if no border is required, this register must still be programmed such that M[HBER] = M[HDER]. This is a 10-bit register, with bit 14 the least significant. Data bus encoding for this register is shown in Figure 15.

Horizontal Cursor Start Register (HCSR): Address 98H

This register defines the time, in units of single pixel periods, from the start of the -HSYC pulse to the start of the cursor display. If M pixels are required in this time, then value (M-6) should be programmed into the HCSR. This is normally an 11-bit register, with bit 13 the least significant. Bits 11 and 12 must be zero except in the High Resolution mode.

In this mode, where each 24 MHz pixel is further divided into four pixels, the cursor sub-position can be defined by programming bits 11 and 12 of the HCSR, which will move the cursor position within the 24 MHz pixel. Refer to the High Resolution Mode section.

Note that only the cursor start position needs to be defined, as the cursor is automatically disabled after 32 pixels. If a cursor smaller than this is required, then the remaining bits in the cursor pattern should be programmed to logical color 00 (transparent). Figure 16 shows the data bus encoding scheme.

Horizontal Interlace Register (HIR): Address 9CH

This register must be programmed if an interlaced sync display is required. Otherwise, it may be ignored. If value L is written into the HCR, the value (L+1)/2 should be written into the HIR. [L is odd.] This is a 10-bit register with bit 14 the least significant. Data bus encoding is shown in Figure 17.

Vertical Cycle Register (VCR): Address A0H

This register defines the period, in units of a raster, of the vertical scan, i.e., display time + flyback time. If N rasters

always be programmed, even when a border is not required. If a border is not required, then the value in the HBSR must be such as to start the border in the same place as the display start (i.e., M[HBSR] = M[HDSR]). This is a 10-bit register with bit 14 the least significant. Data bus encoding is shown in Figure 12.

Horizontal Display Start Register (HDSR): Address 8CH

This register defines the time, in units of two pixel periods, from the start of the -HSYC pulse to the beginning of the video display. The value programmed here depends on the screen mode in use. If M pixels are required in this time, then: in 8-bits per pixel mode, the value (M-5)/2 should be programmed into the HDSR; in 4-bits per pixel mode, value (M-7)/2 should be programmed into the HDSR; in 2-bits per pixel mode, value (M-11)/2 should be programmed into the HDSR; in 1-bit per pixel mode, value (M-19)/2 should be programmed into the HDSR. M must be odd in all

cases. This is a 10-bit register, with bit 14 the least significant. Data bus encoding for this register is shown in Figure 13.

Horizontal Display End Register (HDER): Address 90H

This register defines the time, in units of two-pixel periods, from the start of the horizontal sync pulse to the end of the video display (i.e., the first pixel which is not displayed). The value programmed here depends on the screen mode used. If M pixels are required in this time, then: in 8-bits per pixel mode, value (M-5)/2 should be programmed into the HDSR; in 4-bits per pixel mode, value (M-7)/2 should be programmed into the HDSR; in 2-bits per pixel mode, value (M-11)/2 should be programmed into the HDSR; in 1-bit per pixel mode, value (M-19)/2 should be programmed into the HDSR. M must be odd in all cases. This is a 10-bit register, with bit 14 the least significant. Figure 14 shows data bus encoding of register values.

Data

are required in a complete frame, then value (N-1) should be programmed into the VCR. If interlaced display is used, (N-3)/2 must be programmed into the VCR. [N is odd.] Here N is still the number of rasters in a complete frame, not a field. This is a 10-bit register, with bit 14 the least significant. Figure 18 shows the data bus encoding scheme.

Vertical Sync Width Register (VSWR): Address A4H

This register defines the width, in units of a raster, of the -V/CS pulse. If N rasters are required in the vertical sync pulse, then value (N-1) should be programmed into the VSWR. The minimum value allowed for N is 1. This is a 10-bit register, with bit 14 the least significant. Data bus encoding is shown in Figure 19.

Vertical Border Start Register (VBSSR): Address A8H

This register defines the time, in units of a raster, from the start of the vertical sync pulse to the start of the border display. If N rasters are required in this time, then value (N-1) should be programmed into the VBSSR. If no border is required, then this register must still be programmed, in this case to the same value as the VDSR. This is a 10-bit register, with bit 14 the least significant. Figure 20 shows the data bus encoding.

Vertical Display Start Register (VDSR): Address ACH

This register defines the time, in units of a raster, from the start of the vertical sync pulse to the start of the video display. If N rasters are required in this

time, then value (N-1) should be programmed in the VDSR. This is a 10-bit register, with bit 14 the least significant. The data bus encoding is shown in Figure 21.

Vertical Display End Register (VDER): Address B0H

This register defines the time, in units of a raster, from the start of the vertical sync pulse to the end of the video display (i.e., the first raster on which the display is not present). If N rasters are required in this time, then the value (N-1) should be programmed into the VDER. This is a 10-bit register, with bit 14 the least significant. Figure 22 illustrates the data bus encoding.

Vertical Border End Register (VBBER): Address B4H

This register defines the time, in units of a raster, from the start of the vertical sync pulse to the end of the border display (i.e., the first raster on which the border is not present). If N rasters are required in this time, then the value (N-1) should be programmed into the VBBER. If no border is required, then this register must be programmed to the same value as the VDER. This is a 10-bit register, with bit 14 the least significant. Data bus encoding for this register is shown in Figure 23.

Vertical Cursor Start Register (VCSR): Address B8H

This register defines the time, in units of a raster, from the start of the vertical sync pulse to the start of the cursor display. If N rasters are required in this time, then value (N-1) should be programmed into the VCSR. This is a 10-bit register, with bit 14 being the least significant. Figure 24 shows the data bus encoding for this register.

Vertical Cursor End Register (VCER): Address BCH

This register defines the time, in units of a raster, from the start of the vertical sync pulse to the end of the cursor display (i.e., the first raster on which the cursor is not present). If N rasters are required in this time, then value (N-1) should be programmed into the VCER. This is a 10-bit register, with bit 14 the least significant. Data bus encoding is shown in Figure 25.

5

USING THE VIDC

The DMA Interface

The VIDC has three FIFOs into which DMA data is written. The sound FIFO is four 32-bit words deep, and works independently from the other two FIFOs. The video FIFO is eight 32-bit words deep, and the cursor FIFO is again four 32-bit words deep.

Sound FIFO

Each word of data is strobed into the FIFO on the rising edge of -SDAK. Data is read out of the FIFO into a byte wide latch which then drives the DAC. When the last byte in the FIFO is read into the latch, the signal -SDRQ is driven low, requesting another 16 bytes of data. The signal -SDRQ is driven high when the first -SDAK is received.

The time available to service this data request is dependent on the sound data rate. The minimum value of the SFR is three, which defines a byte-rate of 3 μ s. Therefore, the first word must be loaded into the FIFO less than 3 μ s after the -SDRQ signal is generated.

Cursor FIFO

The cursor FIFO contains 16 bytes of data, which is enough for two rasters of cursor display. When the VIDC is programmed to display a cursor, -VDRQ is driven low at the same time as -HSYC goes low on the first raster on which the cursor is to appear. Data is loaded into the FIFO on the rising edge of -VDAK. The load cycle must be complete before the -HSYC pulse has ended.

-VDRQ is driven high again when the first -VDAK is received. The cursor may be any number of rasters high, and the cursor FIFO requests data during the -HSYC of every alternate raster on which it is displayed.

Video FIFO

The video FIFO is eight 32-bit words deep, and it is arranged as a circular buffer. Data must always be loaded into it in blocks of four words, and this FIFO shares the same -VDRQ and -VDAK signals as the cursor FIFO.

To accommodate the vastly different rates at which video data is required in the different modes, and to accommodate different DRAM speeds, the point at which more data is requested can be varied. This is done by bits 4 and 5 in the Control Register.

During the vertical sync pulse, the FIFO is cleared, and the signal -VDRQ is high. After the -HSYC pulse of the first displayed raster, -VDRQ is driven low. Eight words must now be written into the FIFO by driving -VDAK low eight times. This fills the FIFO. -VDRQ is set high again when the fifth -VDAK is received.

Thereafter, the -VDRQ signal is set low whenever the FIFO empties to the point predetermined by bits 4 and 5 in the Control Register. The -VDRQ signal is normally set high when the first -VDAK signal is received. However, if the data request is not serviced quickly, and the FIFO has emptied to the point where another four words have been read out when the first new data word arrives, then the -VDRQ signal will stay low, requesting another four words of data.

The Video DMA Interface

As noted above, the cursor and video FIFOs share the same DMA Interface signals. Normally, a -VDRQ low during the -HSYC pulse is a request for cursor data, and -VDRQ low at any other times is a request for video data. Figure 28 shows the relationships graphically.

However, often a video request happens just before the end of a raster

requesting data for the next raster. The load cycle for this video request is allowed to overlap the -HSYC pulse, even if a cursor request happens during the -HSYC pulse. Note that in this case the -VDRQ signal may not be driven high between these two cycles. The first cycle must be video data and the second cycle must be cursor data. The cursor load cycle must still be complete before the end of the -HSYC pulse. This is shown in Figure 29.

Figure 30 shows the situation where a cursor is displayed on the first raster of the frame. Note the double video load cycle. The cursor load cycle must not overlap the end of the -HSYC pulse (otherwise data will be loaded into the wrong FIFO), and the first word of video data must be present in the FIFO before the display starts.

Restrictions On Parameters

It is clear from the above that certain restrictions must be applied to the screen parameters, most of which are system dependent. The following paragraphs assume the VIDC is being used in a system with the processor and MEMC and two/one clock page-mode DRAM memory. In this system DRAM cycles consist of an N-cycle (two RCLK clocks) followed by up to three sequential S-cycles (one RCLK clock).

5

FIGURE 28. VIDEO AND CURSOR DMA OPERATION

FIGURE 29. VIDEO DMA OVERLAPPING -HSYC PULSE

FIGURE 30. CURSOR DMA AT THE BEGINNING OF A FRAME

Hence, a VIDC FIFO load cycle consists of $1N + 3S$ requiring five RCLK clocks (417 ns at 12 MHz).

FIFO Request Pointer Values (Control Register Bits [4:5])

The video FIFO is a circular buffer, although the core is asynchronous, with a ripple-through time of 150 ns from the top to the bottom. Data is loaded in blocks of four words, and is read out in bytes, starting with byte 0 of word zero and so on. -VDRQ can be set low half way through reading the last byte of any of word 0-3 (and correspondingly 7-4) according to bits 5-4 in the Control Register. In the high resolution video modes where the bytes are being consumed quickly, the request signal must be set at an earlier point than in the low resolution modes. Selections are defined in Table 3.

The request signal -VDRQ should be brought low as soon as the FIFO can accept the four words of data when they arrive. The minimum time between setting the request and receiving the last word of data is 187 ns + 625 ns = 812 ns (at 8 MHz). [The 187 ns figure

is the minimum time in which MEMC can start a DMA cycle.] If the FIFO is full at the start, then it will have four words spare 150 ns after the start of word 4. [150 ns is the ripple-through time of the FIFO.] Hence, the request should be made at the first opportunity after (812 ns - 150 ns = 662 ns) before the start of word four. The request can be made halfway through the last byte of any of words 0-3 by programming the Control Register.

Depending on the video mode in use, data can be read from the FIFO at 1.5, 2, 3, 4, 6, 8, 12, or 16 Mbytes/second.

Figure 31 shows the case for the 16 Mbytes/second mode. The request must be set at the end of words one and five.

Figure 32 shows the case for the 12 Mbytes/second mode. The request must be set at the end of words two and six.

Figure 33 shows 8 Mbytes per second mode. Again, the request must be set at the end of words two and six.

In all other modes, the request should be set at the end of words three and seven.

Horizontal Sync Pulse Width

The -HSYC pulse width must be long enough to allow a complete load of the cursor FIFO. This is made up as follows:

$$2*[N+3S] (\text{current} + \text{cursor cycles}) + \text{syncmax} + 2*T_{\text{prop}}$$

$$\text{i.e. } 2*625 + 312 + 100 = 1662 \text{ ns.}$$

1	1	3, 7

Syncomax is the maximum time MEMC can take to recognize the DMA request. Tprop is the time taken for the -VDRQ signal to reach MEMC, or the time taken for -VDK to reach VIDC.

The pulse must also be long enough to allow the processor to write to the DMA address generator (DAG) in the MEMC to reset the screen pointer. This may be as follows:

$$3*[N+3S] \text{ (current + cursor + sound cycles) + DAG write.}$$

i.e. $3*625 + 250 = 2125$ ns. Since both these parameters must be met, this larger value must therefore be used.

Horizontal Front Porch Width

The front porch may be zero length. The total time from the end of display to the end of the -HSYC pulse must be more than 1912 ns. As the -HSYC pulse width has to be at least 2125 ns, this does not impose a restriction on the value of the back porch.

Horizontal Front Porch Width

The back porch must be long enough to allow the load of at least one word into the video FIFO before the data is read out again. This is important at the start of the frame because data is required in the bottom of the FIFO at least four pixel-times before the start of display, due to the pipeline delays. Hence the back porch must be greater than:

$$N+3S+N \text{ (current cycle + video N cycle) + syncomax + 2*Tprop + FIFO-ripple + 4 pixels.}$$

$$\text{i.e. } 250 + 375 + 250 + 312 + 100 + 150 + 4*83 = 1769 \text{ ns for 12 MHz displays.}$$

$$\text{or } 250 + 375 + 250 + 312 + 100 + 150 + 4*125 = 1937 \text{ ns for 8 MHz displays.}$$

Vertical Sync Pulse and Porch Width

There are no restrictions on the values of the vertical front porch, back porch, or sync width. The Vertical Sync Width Register (VSWR) may be programmed to a value of 0 which gives a vertical sync width of one raster.

Horizontal Display Width

The number of bits in the pixels of each raster must be a multiple of 128.

Border

The border cannot be disabled. If no border is required, then it should be programmed to start and finish in exactly the same place as the display

TABLE 4. SCREEN MODE SUPPORT

Pixel Rate	Bits/Pixel	FIFO Data Rate	Pixel Rate	Bits/Pixel	FIFO Data Rate
24 MHz	8	Not Supported	12 MHz	8	12 Mbytes / Second
	4	12 Mbytes / Second		4	6 Mbytes / Second
	2	6 Mbytes / Second		2	3 Mbytes / Second
	1	3 Mbytes / Second		1	1.5 Mbytes / Second
16 MHz	8	16 Mbytes / Second	8 MHz	8	8 Mbytes / Second
	4	8 Mbytes / Second		4	4 Mbytes / Second
	2	4 Mbytes / Second		2	2 Mbytes / Second
	1	2 Mbytes / Second		1	Not Supported

(both vertically and horizontally).

Cursor Position

The cursor should not be programmed to be outside the display area vertically, but it may be programmed to start or end outside the display area horizontally. Note that the cursor will not be displayed outside the border area either vertically or horizontally.

DISPLAY FORMATS

Screen Modes

Fourteen of the possible 16 display modes are supported (See Table 4).

Data Display

Pixels are displayed starting at the top left hand corner of the screen, with the least significant end of the first word loaded into the FIFO. In 8-bits per pixel mode, bits 0-7 of word zero are the first displayed pixel. In 4-bits per pixel mode, bits 0-3 of word zero are the first displayed pixel. In 2-bits per pixel mode, bits 0-1 of word zero are the first displayed pixel. In 1-bit per pixel mode, bit zero of word zero is the first displayed pixel.

Logical Data Fields

In 1-bit per pixel mode, the data field selects the palette at location zero or one. The other 14 locations need not be programmed. In 2-bits per pixel mode, the data field addresses the palette at locations zero through three. The other

12 locations need not be programmed. In 4-bits/pixel mode, the data field addresses the palette at all 16 locations. In 8-bits per pixel mode, the least significant 4-bits drive the palette as in 4-bits per pixel mode, and the most significant four bits drive the most significant bits of the RGB DACs directly.

Physical Data Fields

In 1-, 2-, and 4- bits per pixel mode, the physical data field is shown in Figure 34. In 8-bits per pixel mode, the physical data field is shown in Figure 35. The Dn bits come from the palette field and the Ln bits come from the logical field.

Cursor Format

The cursor, in all video modes, is defined to be 32 pixels wide and any number of rasters high. Any pixel may be defined as being transparent, enabling cursors of any shape to be constructed within the 32 pixel horizontal limit. It is always 2-bits per pixel, with bits zero, one in the first word to be loaded into the cursor FIFO representing the first pixel, etc. The logical cursor pixel bit-pairs are defined in Table 5.

The cursor physical field is exactly as the video physical field in 1-, 2-, or 4-bits per pixel modes.

FIGURE 34. PHYSICAL COLOR FIELD DEFINITIONS

TABLE 5. CURSOR LOGICAL COLORS

Cursor Bit		Color
MSB	LSB	
0	0	Transparent
0	1	Logical Color 1
1	0	Logical Color 2
1	1	Logical Color 3

Border Field

The border physical field is exactly as the video physical field in 1-, 2-, and 4-bits per pixel modes.

Controlling the Screen On / Off

The simplest method of turning the screen off is to program the Vertical Display End Register (VDER) to be less than the VDSR. This will not generate any video requests, but will display the border color over the whole screen.

The border can be turned off either by programming it to physical color black, or by programming the VBSR to be greater than the VBER. Doing the latter will also disable the cursor, though cursor data requests will still be generated. Turning the screen back on should only be done during vertical flyback.

Cursor On / Off

The cursor should be turned off by setting the VCER to be less than VCSR. [Value 0 is suggested.] This will also disable cursor data requests. Turning the cursor on, and moving it around should only be done during vertical flyback to prevent flash.

FIGURE 36. EXAMPLE VIDEO OUTPUT CIRCUIT

Suggested Component Values

- Rr - 10 kΩ
- R1 - 330 Ω
- R2 - 68 Ω

D1 should have similar characteristics to the emitter-base junction of Q1

Writing to the Palettes and Other Registers

The palettes may be programmed reliably at any time, but are best programmed during vertical flyback. Changing the values of other registers should only be done during vertical flyback. The signal FLBK is set high from the start of the first raster after the end of display (though it may still be border), until the start of the first raster which is display.

Video DAC Outputs

The video DAC outputs are in the form of current sinks. Each DAC has a resolution of 4-bits, giving a linear transfer characteristic with 16 values.

A digital input value of four zeros gives zero current sink, and a digital input value of four ones gives the maximum current sink. The magnitude of the output is a function of the video reference input current, with the maximum current sink being 15 times the reference input current.

High Resolution Modes

The four bits of digital data which normally drive the red DAC are available to the user on pins -VED3 through -VED0. This pixel rate bit-stream can be externally serialized to a single bit-stream of four times the VIDC pixel rate. With the VIDC operating at 24 MHz, four bits per pixel mode, 96 MHz bit rates are generated giving very high resolution monochrome displays. Alternatively, with an external DAC, 48 MHz grey-level displays are possible.

Referring to the block diagram, it will be noted that the data passes through the High Res. Shifter block before reaching the pins -VED3 - -VED0. This block enables the cursor to be positioned to any (96 MHz) pixel. Note that this block also inverts the data from the red DAC.

When used in this mode, the VIDC must be programmed to a different set of values. But note that the "normal" analog modes of VIDC are still available simply by reprogramming: the addition of the shifter hardware will not affect the other modes, and the sound system is totally independent from this.

- (1) Four-bits per pixel should always be selected.
- (2) The programmed VIDC pixel rate is one quarter of the external pixel

rate. The vertical timing parameters are unaffected by this as they are defined in units of a raster, but the horizontal timing parameters which are defined in units of two (24 MHz) pixels can only be programmed in units of eight (96 MHz) pixels. There are now four times as many pixels on a line as are actually programmed. For example, if a display of 1024 * 1024 is required, the VIDC should be programmed to generate a display of 256 (horizontal) by 1024 (vertical).

- (3) All 16 locations of the video palette should be programmed to a 1:1 logical to physical mapping. Only D[0:3] (red DAC values) need to be programmed, as D[4:11] are ignored. The supremacy bit (D[12]) may be used if required.
- (4) D[4,5] in the Border Color Register must be set to zero. D[0:3] and D[12] may also be programmed if a border is required.
- (5) The cursor palette should be programmed to the following values:
 - cursor color 1 : 10H
 - cursor color 2 : 20H
 - cursor color 3 : 30H
 Supremacy may also be used.

Then the 2-bits which define each cursor pixel are defined in Table 6.

Note that the cursor can only be defined horizontally in units of four (96 MHz) pixels, though it can be positioned anywhere on the screen to within one (96 MHz) pixel. See the section on Horizontal Cursor Start Register for more detail. The hardware should be arranged so that -VED0 is the first bit to be serialized.

TABLE 6. CURSOR COLOR IN HIGH-RESOLUTION MODE

Cursor Bits		Definition
MSB	LSB	
0	0	Transparent
0	1	Cursor Black
1	0	Do Not Use
1	1	Cursor White

FIGURE 37. HIGH RESOLUTION PIXEL GENERATOR

External Synchronization and Mixing

The VIDC has two signals associated with external synchronization applications: SUP and SINK. SUP is an output which can be used to control an external multiplexer for mixing the VIDC output with that from an external source. All video and cursor logical colors from the palettes and the border color can control SUP. When D[12] in any of the above registers is set and that color is being displayed, SUP is driven low. The output is pipelined and is synchronous with the DAC outputs and the -VED3 - -VED0 signals.

The signal SINK is an input which when driven high resets the vertical counters to the first raster. If an interlaced sync display is being generated, then SINK will reset the counters to the first raster of the odd field. The pulse applied to this pin must be shorter than a raster time. The horizontal counters are not affected by this signal. The horizontal synchronization must be done by

phase-locking (or in simple applications, by interrupting) the input clock CKIN. Remember that the sound system is also driven from a derivative of CKIN.

Composite Sync

According to the setting of D[7] in the Control Register, the -VCS can output a composite sync pulse. This is synthesized from the XNOR of vertical and horizontal syncs as shown in Figure 38.

Interlaced Displays

The VIDC can generate an interlaced sync display. An example of interlace timing is shown in Figure 39. Normally the video data in each field is the same. The VIDC Vertical Cycle Register is set to a value $(N-3)/2$, where N is the total number of rasters in a frame. There are $N/2$ raster in the even and odd fields. On raster $(N+1)/2$, the vertical sync pulse is output and the cycle repeats, but this is now the odd field, so the vertical sync pulse is delayed by half a raster time as defined by the value in

FIGURE 38. COMPOSITE SYNC GENERATION

FIGURE 39. INTERLACE DISPLAY TIMING GENERATION

FIGURE 40. SOUND OUTPUT CIRCUIT

the HIR. On the first raster in the odd field which is not vertical sync, a dummy raster is inserted. This makes the odd field $N/2$ rasters long as well.

Sound System

The sound system consists of a four word FIFO and byte wide latch which drive a 7-bit exponential DAC. The eighth bit steers the DAC output to one of two pairs of output pins, one pair designated "+", and the other pair designated "-". The sound signal is generated externally by integrating and then subtracting these two pairs of signals. An example circuit is shown in Figure 40. The integration is performed by the capacitor C.

Stereo image is synthesized by time-division multiplexing the output between the "left" and "right" pair of output signals as shown in Figure 41. The first quarter of each sample is muted to allow for DAC settling and deglitching. The stereo image is specified for each channel by programming the corresponding Stereo Image Register.

The system can operate in 1, 2, 4, or 8 channel modes. In 8 channel mode, the channels are sampled sequentially, starting with the first byte of data, which is channel 0; the second byte of data is channel 1 and so on. The external integrating time constant must be long enough to integrate over a complete sample cycle. In 4 channel mode, the fifth byte to be sampled is again channel 0, so Stereo Image Register 4 must be programmed to the same value as Stereo Image Register 0, and so on. In 2 channel mode, Stereo Image Registers 0, 2, 4, and 6 correspond to channel 0 and Stereo Image Registers 1, 3, 5, and 7 correspond to channel 1. In single channel mode, all eight Stereo Image Registers should contain the same value.

5

FIGURE 41. STEREO IMAGE SYNTHESIS

The sample rate is selectable by the SFR in units of 1 μ s, with a minimum value of 3 μ s. Clearly, in eight channel mode the bytes for each channel are sampled with one-eighth of the frequency of single channel mode for a given value in the SFR.

The DAC transfer characteristic consists of eight linear segments (chords). Each chord consists of 16 steps, and the step size in one chord is twice the step in the preceding chord. This gives an approximation to the "125 law." The sound data field format is shown in Figure 42.

The outputs are in the form of current sinks. The magnitude of the output is a function of the sound reference input current. The reference current is equal to the step size in the highest chord, which is 8i in Figure 43.

A.C. TEST WAVEFORMS

A.C. TEST LOAD CIRCUIT

- Notes:**
1. The data must be setup before -VIDW goes active (low) because the data also contains the register address.
 2. For pixel rates of 12 and 24 MHz, the outputs are referenced to the rising edge of CKIN. For pixel rates of 8 and 16MHz, the outputs are alternately referenced to either edge of CKIN.
 3. The -SD3 - -SD0 signals are output one pixel time before the corresponding -VED3 - -VED0 due to pipeline differences.
 4. Assumes a 5 pF external load.
 5. -VDRQ or -SDRQ are cleared by the first -VDAK or -SDAK respectively, as long as no request is pending.

		Sound DAC	-	VDD - 1.5	-	V	ISOUT = -2.0 mA
CCOMP	Current Compliance	Video DACs	-	4.5	-	mA	VOUT = VDD - 0.7
		Sound DAC	-	3	-	mA	VOUT = VDD - 0.7

- Notes:**
1. Measured at 24 MHz pixel rate. This value does not include any current output by the video DACs.
 2. Not more than one output should be shorted to either rail and for no longer than one second.
 3. This assumes 10 kΩ resistors to VDD.
 4. This value is the current that inputs or outputs can tolerate before the chip latches up. This condition should be avoided to prevent device damage.

PACKAGE OUTLINES (Cont.)
84-PIN PLASTIC LEADED CHIP CARRIER (PLCC)

- NOTES: UNLESS OTHERWISE SPECIFIED.
1. TOLERANCE TO BE +/- .005 (0.127).
 2. LEADFRAME MATERIAL: COPPER.
 3. LEAD FINISH: MATTE TIN PLATE OR SOLDER DIP.
 4. SPACING TO BE MAINTAINED BETWEEN FORMED LEAD AND MOLDED PLASTIC ALONG FULL LENGTH OF LEAD.
 5. MOLDED PLASTIC DIMENSION DOES NOT INCLUDE SIDE FLASH BURR, WHICH IS .010 (0.254) MAX ON FOUR SIDES.
 6. CONTROLLING DIMENSIONS ARE METRIC, ALL METRIC DIMENSIONS ARE IN PARENTHESES.
