

# 60V, 500mA, Ultra-Small, High-Efficiency, Synchronous Step-Down DC-DC Converter

### **General Description**

The MAX17501 high-efficiency, high-voltage, synchronous step-down DC-DC converter operates over a 4.5V to 60V input voltage range and is designed for a wide range of applications. The ultra-wide-input operation makes it ideal for not only industrial control and building automation, but also base stations, telecom, home entertainment and automotive applications. It delivers output currents up to 500mA, at output voltages of 3.3V and 5V. The output voltage is accurate within  $\pm 1.6\%$  over temperature. The device operates over the -40°C to +125°C industrial temperature range and is available in a tiny, 10-pin (3mm x 2mm) TDFN with an exposed pad.

The device features peak-current-mode control with pulse-width modulation (PWM). The PWM operation ensures constant switching frequency at all operating conditions. The low-resistance, on-chip, pMOS/nMOS switches ensure high efficiency at full load while minimizing the critical inductances, making the layout a much simpler task compared to discrete solutions.

The device offers fixed switching frequency of 600kHz. To reduce input inrush current, the device offers an adjustable voltage soft-start feature with an external capacitor from the SS pin to ground. The device also incorporates an output enable/undervoltage lockout pin (EN/UVLO) that allows the user to turn on the part at the desired input-voltage level. An open-drain RESET pin provides a delayed power-good signal to the system upon achieving successful regulation of the output voltage. The device supports hiccup-mode current-limit protection for low power dissipation under overload and output short-circuit conditions.

### **Applications**

Industrial Process Control HVAC and Building Control General-Purpose Point-of-Load Base Station, VOIP, Telecom Home Theater Automotive Battery-Powered Equipment

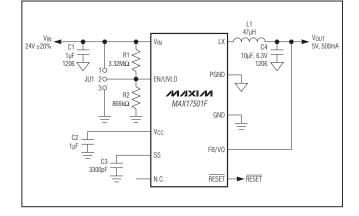

Dattory i oworod Equipmont

Ordering Information appears at end of data sheet.

### **Benefits and Features**

- Eliminate External Components and Reduce Total Cost
  - No Schottky-Synchronous Operation for High Efficiency and Reduced Cost
  - ♦ Internal Compensation for Ultra-Compact Layout
  - ♦ All-Ceramic Capacitors
- Reduce Number of DC-DC Regulators to Stock
  Wide 4.5V to 60V Operating-Voltage Range
  - ♦ Fixed 3.3V and 5V Output
  - Oelivers Up to 500mA Over Temperature
  - ♦ 600kHz Switching Frequency
- Reduce Power Dissipation
  - ♦ Peak Efficiency > 90%
  - ♦ Shutdown Current = 1µA (typ)
- Operate Reliably in Adverse Industrial Environments
  Hiccup-Mode Current Limit and Autoretry Startup
  - ♦ Built-In Output-Voltage Monitoring (Open-Drain RESET Pin)
  - Resistor-Programmable UVLO Threshold
  - Increased Safety with Adjustable Soft-Start and Prebiased Power-Up
  - Optional Adjustable Output and PFM (Available Upon Factory Request)

### **ABSOLUTE MAXIMUM RATINGS**

V <sub>IN</sub> to GND	0.3V to +70V
EN/UVLO to GND	0.3V to V <sub>IN</sub> + 0.3V
LX to PGND	0.3V to +70V
FB, RESET, COMP, SS to GND	0.3V to 6V
V <sub>CC</sub> to GND	0.3V to +6V
GND to PGND	0.3V to +0.3V
LX Total RMS Current	±1.6A
Output Short-Circuit Duration	Continuous

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### PACKAGE THERMAL CHARACTERISTICS (Note 1)

Thermal Resistance

TDFN

Junction-to-Ambient Thermal Resistance ( $\theta_{JA}$ ) .......67.3°C/W

Note 1: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a fourlayer board. For detailed information on package thermal considerations, refer to <u>www.maxim-ic.com/thermal-tutorial</u>.

**Pin Configuration** 

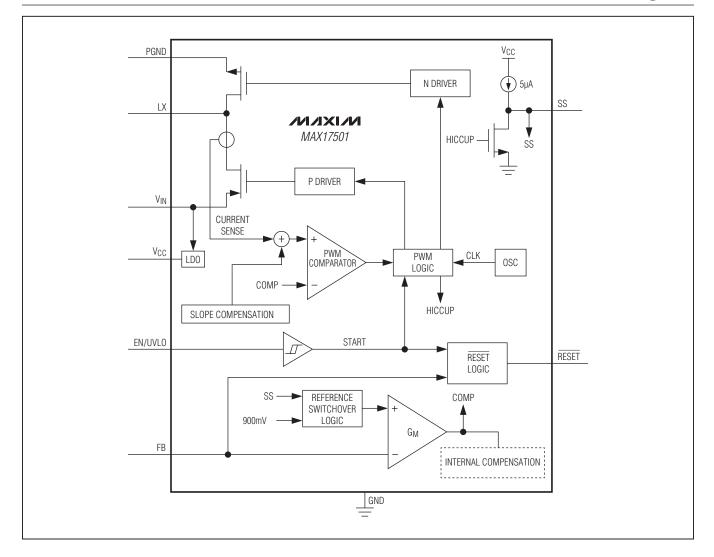

### **Pin Description**

PIN	NAME	FUNCTION
1	PGND	Power Ground. Connect PGND externally to the power ground plane. Connect GND and PGND pins together at the ground return path of the $V_{CC}$ bypass capacitor.
2	V <sub>IN</sub>	Power-Supply Input. The input supply range is from 4.5V to 60V.
3	EN/UVLO	Enable/Undervoltage Lockout Input. Drive EN/UVLO high to enable the output voltage. Connect to the center of resistive divider between $V_{\rm IN}$ and GND to set the input voltage (undervoltage threshold) at which the device turns on. Pull up to $V_{\rm IN}$ for always on.
4	V <sub>CC</sub>	5V LDO Output. Bypass V <sub>CC</sub> with 1µF ceramic capacitance to GND.
5	FB	Feedback Input. Directly connect FB to the output.
6	SS	Soft-Start Input. Connect a capacitor from SS to GND to set the soft-start time.
7	N.C.	No Connection. Leave unconnected.
8	RESET	Open-Drain RESET Output. The RESET output is driven low if FB drops below 92.5% of its set value. RESET goes high 1024 clock cycles after FB rises above 95.5% of its set value.
9	GND	Analog Ground
10	LX	Switching Node. Connect LX to the switching side of the inductor. LX is high impedance when the device is in shutdown mode.
	EP	Exposed Pad. Connect to the GND pin of the IC. Connect to a large copper plane below the IC to improve heat dissipation capability.

# 60V, 500mA, Ultra-Small, High-Efficiency, Synchronous Step-Down DC-DC Converter

**Block Diagram** 

# 60V, 500mA, Ultra-Small, High-Efficiency, Synchronous Step-Down DC-DC Converter

### **Detailed Description**

The MAX17501 step-down regulator operates from 4.5V to 60V and delivers up to 500mA load current. Output voltage regulation accuracy meets  $\pm 1.6\%$  over load, line, and temperature.

The device uses a peak-current-mode-control scheme. It employs synchronous rectification. An internal transconductance error amplifier produces an integrated error voltage. The error voltage sets the duty cycle using a PWM comparator, a high-side current-sense amplifier, and a slope-compensation generator. At each rising edge of the clock, the high-side p-channel MOSFET turns on and remains on until either the appropriate or maximum duty cycle is reached, or the peak-current limit is detected.

During the high-side MOSFET's on-time, the inductor current ramps up. During the second half of the switching cycle, the high-side MOSFET turns off and the low-side n-channel MOSFET turns on. The inductor releases the stored energy as its current ramps down, and provides current to the output (the internal low RD<sub>SON</sub> pMOS/ nMOS switches ensure high efficiency at full load).

This device also integrates enable/undervoltage lockout (EN/UVLO), adjustable soft-start time (SS), and opendrain reset output (RESET) functionality.

#### **Linear Regulator (Vcc)**

An internal linear regulator (V<sub>CC</sub>) provides a 5V nominal supply to power the internal blocks and the low-side MOSFET driver. The output of the V<sub>CC</sub> linear regulator should be bypassed with a 1µF ceramic capacitor to GND. The device employs an undervoltage-lockout circuit that disables the internal linear regulator when V<sub>CC</sub> falls below 3.7V (typ). The 300mV UVLO hysteresis prevents chattering on power-up/power-down. The internal V<sub>CC</sub> linear regulator can source up to 40mA (typ) to supply the device and to power the low-side gate driver.

#### **Switching Frequency**

The devices have a fixed 600kHz switching frequency. The minimum duty ratio at which the devices can operate is 7.7%.

#### **Overcurrent Protection/Hiccup Mode**

The device is provided with a robust overcurrentprotection scheme that protects the device under overload and output short-circuit conditions. A cycle-bycycle peak-current limit turns off the high-side MOSFET whenever the high-side switch current exceeds an internal limit of 800mA (typ). A runaway-current limit on the high-side switch current at 900mA (typ) protects the device under high input voltage, short-circuit conditions when there is insufficient output voltage available to restore the inductor current that built up during the on period of the step-down converter. One occurrence of the runaway-current limit triggers a hiccup mode. In addition, if due to a fault condition, output voltage drops to 71.1% (typ) of its nominal value any time after soft-start is complete, and hiccup mode is triggered. In hiccup mode, the converter is protected by suspending switching for a hiccup timeout period of 32,768 clock cycles. Once the hiccup timeout period expires, soft-start is attempted again.

#### **RESET** Output

The device includes a RESET comparator to monitor the output voltage. The open-drain RESET output requires an external pullup resistor. RESET can sink 2mA of current while low. RESET goes high (high impedance) 1024 switching cycles after the regulator output increases above 95.5% of the designed nominal regulated voltage. RESET goes low when the regulator output voltage drops to below 92.5% of the nominal regulated voltage. RESET goes low during thermal shutdown.

#### **Prebiased Output**

When the device starts into a prebiased output, both the high-side and low-side switches are turned off so that the converter does not sink current from the output. Highside and low-side switches do not start switching until the PWM comparator commands the first PWM pulse, at which point switching commences first with the high-side switch. The output voltage is then smoothly ramped up to the target value in alignment with the internal reference.

#### **Thermal-Overload Protection**

Thermal-overload protection limits total power dissipation in the device. When the junction temperature of the device exceeds +165°C, an on-chip thermal sensor shuts down the device, allowing the device to cool. The thermal sensor turns the device on again after the junction temperature cools by 10°C. Soft-start resets during thermal shutdown. Carefully evaluate the total power dissipation (see the *Power Dissipation* section) to avoid unwanted triggering of the thermal-overload protection in normal operation.

# 60V, 500mA, Ultra-Small, High-Efficiency, Synchronous Step-Down DC-DC Converter

### **Applications Information**

#### **Input Capacitor Selection**

The discontinuous input-current waveform of the buck converter causes large ripple currents in the input capacitor. The switching frequency, peak inductor current, and the allowable peak-to-peak voltage ripple that reflects back to the source dictate the capacitance requirement. The device's high switching frequency allows the use of smaller value input capacitors. X7R capacitors are recommended in industrial applications for their temperature stability. A minimum value of 1µF should be used for the input capacitor. Higher values help reduce the ripple on the input DC bus further. In applications where the source is located distant from the device input, an electrolytic capacitor should be added in parallel to the 1µF ceramic capacitor to provide necessary damping for potential oscillations caused by the longer input power path and input ceramic capacitor.

#### **Inductor Selection**

Three key inductor parameters must be specified for operation with the device: inductance value (L), inductor saturation current ( $I_{SAT}$ ), and DC resistance ( $R_{DCR}$ ). To determine the inductance value, select the ratio of inductor peak-to-peak ripple current to the DC average current (LIR). For LIR values that are too high, the RMS currents are high, and therefore the inductor I<sup>2</sup>R losses are high. For LIR values that are too low, the inductance values are high and consequently the inductor DC resistance is also high, and therefore inductor I<sup>2</sup>R losses are high as well. A good compromise between size and loss is a 30% peak-to-peak ripple current to average-current ratio (LIR = 0.3). The switching frequency, input voltage, output voltage, and selected LIR determine the inductor value as follows:

$$L = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times f_{SW} \times I_{OUT} \times LIR}$$

where  $V_{IN},\,V_{OUT},$  and  $I_{OUT}$  are nominal values. The switching frequency is 600kHz for the MAX17501E/ MAX17501F. Select a low-loss inductor closest to the calculated value with acceptable dimensions and having the lowest possible DC resistance.

The saturation current rating ( $I_{SAT}$ ) of the inductor must be high enough to ensure that saturation can occur only above the peak current-limit value ( $I_{PEAK-LIMIT}$ (typ) = 0.8A for the device). A variety of inductors from different suppliers are available to meet this requirement (e.g., inductors from the Coilcraft LPS6235 series).

See <u>Table 1</u> to select inductors for 5V and 3.3V fixed output-voltage applications based on the MAX17501E/ MAX17501F.

#### **Output Capacitor Selection**

X7R ceramic output capacitors are preferred due to their stability over temperature in industrial applications. The output capacitor is usually sized to support a step load of 50% of the maximum output current in the application, such that the output-voltage deviation is contained to 3% of the output-voltage change. The output capacitance can be calculated as follows:

$$C_{OUT} = \frac{1}{2} \times \frac{I_{STEP} \times I_{RESPONSE}}{\Delta V_{OUT}}$$
$$t_{RESPONSE} \cong (\frac{0.33}{f_C} + \frac{1}{f_{SW}})$$

where I<sub>STEP</sub> is the load current step, t<sub>RESPONSE</sub> is the response time of the controller,  $\Delta V_{OUT}$  is the allowable output-voltage deviation, f<sub>C</sub> is the target closed-loop crossover frequency, and f<sub>SW</sub> is the switching frequency. f<sub>C</sub> is generally chosen to be 1/8 to 1/10 of f<sub>SW</sub>.

Use <u>Table 2</u> to select output capacitors for fixed 5V and 3.3V output-voltage applications based on the MAX17501E/MAX17501F.

V <sub>OUT</sub> (V)	I <sub>OUT</sub> (max) (mA)	L (µH)	MINIMUM I <sub>SAT</sub> (mA)	SUGGESTED PART
5	500	47	800	Coilcraft LPS6235-473ML_
3.3	500	33	800	Coilcraft LPS6235-333ML_

### **Table 1. Inductor Selection**

# 60V, 500mA, Ultra-Small, High-Efficiency, Synchronous Step-Down DC-DC Converter

#### Table 2. Output Capacitor Selection

V <sub>OUT</sub> (V)	I <sub>OUT</sub> (max) (mA)	ТҮРЕ	VOLTAGE RATING (V)	SUGGESTED PART
5	500	10µF/1206/X7R	6.3	Murata GRM31CR70J106KA01L
3.3	500	10µF/1206/X7R	6.3	Murata GRM31CR70J106KA01L

#### **Soft-Start Capacitor Selection**

The device implements adjustable soft-start operation for the synchronous step-down converter. A capacitor connected from the SS pin to GND programs the soft-start period.

The soft-start time ( $t_{SS}$ ) is related to the capacitor connected at SS ( $C_{SS}$ ) by the following equation:

#### $C_{SS} = 5.55 \times t_{SS}$

where  $t_{SS}$  is in milliseconds and  $C_{SS}$  is in nanofarads. For example, to have a 1.8ms soft-start time, a 10nF capacitor should be connected from the SS pin to GND.

#### Setting the Input Undervoltage Lockout Level

The device offers an adjustable input undervoltage-lockout level. Set the voltage at which the device turns on with a resistive voltage-divider connected from  $V_{\rm IN}$  to GND (see Figure 1). Connect the center node of the divider to EN/UVLO.

Choose R1 to be  $3.3M\Omega$ , and then calculate R2 as follows:

$$R2 = \frac{R1 \times 1.218}{(V_{INU} - 1.218)}$$

where  $V_{\mbox{\rm INU}}$  is the voltage at which the device is required to turn on.

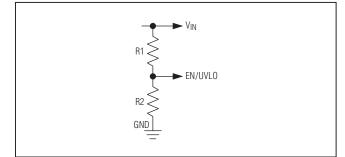

Figure 1. Adjustable EN/UVLO Network

#### **Power Dissipation**

It should be ensured that the junction temperature of the device does not exceed +125°C under the operating conditions specified for the power supply.

At a particular operating condition, the power losses that lead to temperature rise of the device are estimated as follows:

$$P_{LOSS} = \left(P_{OUT} \times \left(\frac{1}{\eta} - 1\right)\right) - \left(I_{OUT}^{2} \times R_{DCR}\right)$$
$$P_{OUT} = V_{OUT} \times I_{OUT}$$

where  $P_{OUT}$  is the output power,  $\eta$  is is the efficiency of the device, and  $R_{DCR}$  is the DC resistance of the output Inductor (see the <u>Typical Operating Characteristics</u> for more information on efficiency at typical operating conditions).

The maximum power that can be dissipated in the device's 10-pin TDFN-EP package is 1188.7mW at +70°C temperature. The power dissipation capability should be derated as the temperature goes above +70°C at 14.9mW/°C. For a multilayer board, the thermal performance metrics for the package are given below:

$$\theta_{JA} = 67.3^{\circ}C/W$$
  
 $\theta_{JC} = 18.2^{\circ}C/W$ 

The junction temperature of the device can be estimated at any given maximum ambient temperature  $(T_{A_MAX})$  from the following equation:

$$T_{J_{MAX}} = T_{A_{MAX}} + (\theta_{JA} \times P_{LOSS})$$

If the application has a thermal-management system that ensures that the exposed pad of the device is maintained at a given temperature ( $T_{EP}MAX$ ) by using proper heat sinks, then the junction temperature of the device can be estimated at any given maximum ambient temperature from the equation below:

$$T_{J_{MAX}} = T_{EP_{MAX}} + (\theta_{JC} \times P_{LOSS})$$

# 60V, 500mA, Ultra-Small, High-Efficiency, Synchronous Step-Down DC-DC Converter

#### **PCB Layout Guidelines**

All connections carrying pulsed currents must be very short and as wide as possible. The inductance of these connections must be kept to an absolute minimum due to the high di/dt of the currents. Since inductance of a current-carrying loop is proportional to the area enclosed by the loop, if the loop area is made very small inductance is reduced. Additionally, small-current loop areas reduce radiated EMI.

A ceramic input filter capacitor should be placed close to the V<sub>IN</sub> pin of the device. This eliminates as much trace inductance effects as possible and gives the device a cleaner voltage supply. The bypass capacitor for the V<sub>CC</sub> pin should also be placed close to the pin to reduce effects of trace impedance. The feedback trace should be routed as far as possible from the inductor.

When routing the circuitry around the device, the analog small-signal ground and the power ground for switching currents must be kept separate. They should be connected together at a point where switching activity is at minimum, typically the return terminal of the  $V_{CC}$  bypass capacitor. This helps to keep the analog ground quiet. The ground plane should be kept continuous/ unbroken as much as possible. No trace carrying high switching current should be placed directly over any ground plane discontinuity.

PCB layout also affects the thermal performance of the design. A number of thermal vias that connect to a large ground plane should be provided under the exposed pad of the device, for efficient heat dissipation. Several vias in parallel have lower impedance than a single via.

For a sample layout that ensures first-pass success, refer to the MAX17501 evaluation kit layout available at **www.maxim-ic.com**.
