System Power Management for Mobile Handset

MAX8939

General Description

The MAX8939 power management IC contains the necessary supplies and features for supporting cell phone designs based on the Intel Mobile Communications (IMC) 61XX 3G platform. Designed to power all peripheral components in the platform, the MAX8939 also provides the necessary signals to control the 61XX baseband processor.

The integrated lithium-ion (Li+) charger is protected up to 28V input and features a protected output voltage for supply of a USB transceiver. Proprietary thermal-regulation circuitry limits the die temperature during fast-charging or when the IC is exposed to high ambient temperatures, allowing maximum charging current without damaging the IC. A dedicated current regulator is included for driving a charge indicator LED.

Four programmable low-noise, low-dropout linear regulators (LDOs) provide the supply for noise sensitive peripherals. A high power vibrator driver is I²C programmable in 70 PWM levels and 4 output voltages. The MAX8939 also offers two step-up converters; one high power, low voltage (5V) to supply an external audio amplifier or camera flash, and a high voltage (28V) supply for the display and keyboard backlight. Two integrated 25mA current regulators provide independent ramp-up and ramp-down control, programmable through I²C.

The MAX8939 is a highly integrated IC that requires very few external components and is available in a compact 2.5mm x 3.0mm, 0.65mm max height wafer level package (WLP).

Applications

Companion Chip for Cell Phones/Smartphones

Features

- ◆ **Step-Up Converter**
 - 700mA Guaranteed Output Current
 - I²C Programmable Output 3.5V to 5.0V in 16 Steps
 - Over 90% Efficiency
 - On-Chip FET and Synchronous Rectifier
 - Fixed 2MHz PWM Switching
 - Small 2.2μH to 10μH Inductor
- ◆ **WLED Boost Converter**
 - 28V Max Step-Up Output Voltage
 - 60mA Output Current
 - Integrated nMOS Power Switch
 - Over 90% Efficiency
 - Fixed 2MHz Switching
 - Small 4.7μH to 10μH Inductor

Two 25mA Individually Programmable Current Regulators
I²C Programmable Output Current (50μA to 25.25mA) with 128-Step Pseudo Log Dimming
Individually Programmable Ramp (Up/Down) Timers
Low Dropout (150mV max)

- ◆ **Linear One-Cell Li+ Battery Charger**
 - No External MOSFET, Reverse Blocking Diode, or Current-Sense Resistor
 - Programmable Fast-Charge Current (1.5A_{RMS} max)
 - Programmable Top-Off Current Threshold
 - Proprietary Die Temperature Regulation Control
 - 4.1V to 10V Input Voltage Range with Input Overvoltage Protection Up to 28V
 - Low-Dropout Voltage (300mV at 500mA)
 - Input Power-Source Detection Output
 - Input Overvoltage Protected 4.75V Output (SAFE_OUT) from IN
 - Charge Current Monitor Output
 - Indicator LED
 - Hardware Input Enable
 - 5s Watchdog Feature During Charge
- ◆ **Four Low-Noise LDOs**
 - 1x 400mA, 2 x 200mA and 1x 100mA Output Current
 - High 65dB (typ) PSRR
 - Low Noise (45μV_{RMS} typ)
 - 1.7V to 3.2V Programmable Output Voltage
 - Low Quiescent Current (25μA typ)
 - 400mA LDO with Hardware Enable Input
- ◆ **Vibrator Driver**
 - Guaranteed 200mA Output Current
 - Programmable Output Voltage 1.3V to V_{IN}V_{IB}
 - Repetition Frequency 23.8kHz
 - PWM Speed Control in 70 steps
 - Active Stop Brake
- ◆ **Control Interface for 61XX Baseband**
 - MAX8939 Control Through I²C
 - RESET_IN Reset Input
 - Charger Detect PWR_ON_CMP Output
 - IRQ Interrupt Output
- ◆ 2.7V to 5.5V Supply Voltage Range
- ◆ Thermal Shutdown

Ordering Information

PART	TEMP RANGE	PIN-PACKAGE
MAX8939EWW+T	-40°C to +85°C	30 WLP (0.5mm pitch)

+Denotes a lead(Pb)-free/RoHS-compliant package.

T = Tape and reel.

Typical Operating Circuit appears at end of data sheet.

System Power Management for Mobile Handset

ABSOLUTE MAXIMUM RATINGS

BATT, OUT1, SAFE_OUT, and INVIB to AGND-0.3V to +6.0V
 CHG_IN, OUT2, LED1, and LED2 to AGND.....-0.3V to +30V
 LED3 and CHG_MON to AGND....-0.3V to (VSAFE_OUT + 0.3V)
 COMP2, IRQ, RESET_IN, COMP1, SCL, SDA, CHG,
 PWR_ON_CMP, REF, LDO1, LDO2, LDO3, LDO4,
 and LDO1_EN to AGND.....-0.3V to (VBATT + 0.3V)
 OUTVIB to AGND.....-0.3V to (VINVIB + 0.3V)
 PGND1 and PGND2 to AGND-0.3V to +0.3V
 LX1, LX2 Current (Note 1)..... 1.7ARMS

Continuous Power Dissipation (TA = +70°C)
 WLP (derate 24.4mW/°C above +70°C)..... 1.9W
 Junction to Ambient Thermal Resistance (θJA)
 (Note 2).....41°C/W
 Operating Temperature.....-40°C to +85°C
 Junction Temperature+150°C
 Storage Temperature Range.....-65°C to +150°C
 Soldering Temperature (reflow)+260°C

Note 1: LX1 has internal clamp diodes to PGND1 and OUT1. LX2 has internal clamp diodes to PGND2 and OUT2. Applications that forward bias these diodes should take care not to exceed the IC package power dissipation limit.

Note 2: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to <http://www.maxim-ic.com/thermal-tutorial>.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

(VBATT = 3.7V, VCHG_IN = 5.0V, circuit of Figure 1, TA = -40°C to +85°C, unless otherwise noted. Typical values are at TA = +25°C.)

PARAMETER	CONDITIONS	MIN	TYP	MAX	UNITS
BATT					
BATT Operating Voltage		2.9		5.5	V
BATT Shutdown Supply Current	All outputs off, I ² C disabled, VSCL = VSDA = VRESET_IN = 0V		0.4	1	μA
			0.4		
BATT Standby Supply Current	All outputs off, VSCL = VSDA = VRESET_IN = 1.8V, I ² C ready		5	10	μA
			5		
BATT Biasing Supply Current	I ² C ready, one or more outputs on		60		μA
Undervoltage Lockout (UVLO) Threshold	BATT rising	2.6	2.75	2.9	V
Undervoltage Lockout Hysteresis			100		mV
THERMAL SHUTDOWN					
Threshold			+160		°C
Hysteresis			20		°C
REFERENCE					
Reference Output Voltage			1.200		V
Reference Supply Rejection			0.2		mV
LOGIC AND CONTROL INPUTS					
Input Low Level	SDA, SCL, LDO1_EN, CHG, and RESET_IN			0.4	V
Input High Level	SDA, SCL, LDO1_EN, CHG, and RESET_IN	1.40			V
Logic-Input Current	SDA, SCL, LDO1_EN, CHG, and RESET_IN, 0 < VIN < 5.5V	TA = +25°C	-1	+1	μA
		TA = +85°C		0.1	

System Power Management for Mobile Handset

MAX8939

ELECTRICAL CHARACTERISTICS (continued)

(VBATT = 3.7V, VCHG_IN = 5.0V, circuit of Figure 1, TA = -40°C to +85°C, unless otherwise noted. Typical values are at TA = +25°C.)

PARAMETER	CONDITIONS	MIN	TYP	MAX	UNITS
LOGIC AND CONTROL OUTPUTS					
IRQ (Open-Drain Output) Output Low Voltage	IIRQ = 2mA			0.4	V
PWR_ON_CMP (Open-Drain Output) Output Low Voltage	IPWR_ON_CMP = 2mA			0.4	V
SDA Output Low Level	ISDA = 6mA			0.4	V
I²C SERIAL INTERFACE (VSCL = VSDA = 3V) (Figure 15)					
Clock Frequency				400	kHz
Bus-Free Time Between START and STOP	tBUF	1.3			μs
Hold Time Repeated START Condition	tHD_STA	0.6			μs
SCL Low Period	tLOW	1.3			μs
SCL High Period	tHIGH	0.6			μs
Setup Time Repeated START Condition	tSU_STA	0.6			μs
SDA Hold Time	tHD_DAT	0			μs
SDA Setup time	tSU_DAT	100			ns
Maximum Pulse Width of Spikes that Must Be Suppressed by the Input Filter of Both DATA and CLK Signals			50		ns
Setup Time for STOP Condition	tSU_STO	0.6			μs
CHG_IN					
Input Operating Range		4.1		10	V
CHG_IN Trip Point	VCHG_IN - VBATT, rising	200	300	400	mV
	VCHG_IN - VBATT, falling		100		
	VCHG_IN - VBATT, hysteresis		200		
Input Undervoltage Threshold (UV)	VCHG_IN rising, 500mV hysteresis (typ)	3.9	4.0	4.1	V
Input Overvoltage Threshold (OVP)	VCHG_IN rising, 200mV hysteresis (typ)	10.2	10.6	11	V
Input Supply Current	IBATT = 0mA		750	1500	μA
Shutdown Input Current	Charger disabled			500	μA
CHG_IN to BATT Dropout On-Resistance	VCHG_IN = 3.7V, VBATT = 3.6V		0.4	0.8	Ω
SAFE_OUT					
SAFE_OUT Regulated Output	ISAFE_OUT = 15mA, VCHG_IN = 5V, TA = 0°C to +85°C	4.75	4.90	5.00	V
	ISAFE_OUT = 15mA, VCHG_IN = 10V, TA = 0°C to +85°C			5.2	
SAFE_OUT Current Limit			100		mA

MAX8939

ELECTRICAL CHARACTERISTICS (continued)

(VBATT = 3.7V, VCHG_IN = 5.0V, circuit of Figure 1, TA = -40°C to +85°C, unless otherwise noted. Typical values are at TA = +25°C.)

PARAMETER	CONDITIONS	MIN	TYP	MAX	UNITS
LED1, LED2					
Current Regulator Dropout Voltage (Note 3)	25.25mA setting			200	mV
	5.05mA setting			150	
LED_ Regulation Voltage			350		mV
LED_ Current Accuracy	TA = +25°C, ILED_ = 25.25mA	-3		+3	%
	TA = -40°C to +85°C, ILED_ = 25.25mA	-5		+5	
Leakage Current	TA = +25°C, in shutdown		0.01	1	μA
	TA = +85°C, in shutdown		1		
LX2					
nFET Current Limit		710	860		mA
nFET On-Resistance	ILX2 = 200mA		0.3	0.7	Ω
LX2 Leakage Current	TA = +25°C, 28V, shutdown		0.01	1	μA
	TA = +85°C, 28V, shutdown		1		
Operating Frequency		1.8	2	2.2	MHz
Maximum Duty Cycle	VLED1 or VLED2 = 0.2V		92		%
COMP2					
Transconductance			20		μs
Soft-Start Charge Current			60		μA
Discharge Pulldown			20		kΩ
PROTECTION					
Overvoltage Threshold	VOUT2 rising	28		30	V
Overvoltage Hysteresis			4		V
Open LED Detection			100	120	mV
Shorted LED Detection		VOUT2 - 2.2V	VOUT2 - 0.7V		V

Note 1: The monitoring voltage is proportional to the charging current with a ratio depending on the programmed fast-charge current. For the current equal to the fast-charge current, the monitoring voltage is typically 1.2V.

Note 2: The maximum CHG_IN current is the typical value plus 10% for currents up 700mA and the typical value plus 15% for higher currents.

Note 3: LED dropout voltage is defined as the LED_ to ground voltage when current into LED_ drops 10% from the value at VLED_ = 0.5V.

System Power Management for Mobile Handset

BATTERY CHARGER

System Power Management for Mobile Handset

Pin Configuration

MAX8939

Pin Description

PIN	NAME	FUNCTION
A1	PGND2	Power Ground for WLED Boost Converter. Connect PGND1, PGND2, and AGND to the PCB ground plane.
A2	LX2	Inductor Connection and Switching Node for WLED Boost Converter
A3	OUT2	WLED Step-Up Converter Output. Connect a 1 μ F capacitor from OUT2 to PGND2.
A4	OUT1	Step-Up Converter Output. Connect a 2.2 μ F capacitor from OUT1 to ground.
A5	LX1	Inductor Connection and Switching Node for OUT1 Step-Up Converter
A6	PGND1	Power Ground for OUT1 Step-Up Converter. Connect PGND1, PGND2, and AGND to the PCB ground plane.
B1	COMP2	Step-Up Compensation Node for OUT2 Step-Up Converter. Connect a 0.22 μ F ceramic capacitor from COMP to ground. The applied COMP capacitance stabilizes the converter and sets the soft-start time. COMP discharges to ground through a 20k Ω resistance when in shutdown.
B2	LED1	25mA LED Current Regulator. Connect LED1 to the cathode of the first LED string.
B3	$\overline{\text{RESET_IN}}$	Active-Low Reset Input. Pulse $\overline{\text{RESET_IN}}$ low to reset all registers (except STATUS and EVENT) to their default state.
B4	SCL	Clock Input for I ² C Serial Interface. High impedance when the I ² C interface is off.
B5	LDO1_EN	Enable Input for LDO1. Drive LDO1_EN high to enable LDO1, or low to disable LDO1. Once LDO1 is enabled or disabled through I ² C, the state of LDO1_EN is ignored until reset.
B6	COMP1	Compensation for OUT1 Step-Up Converter. Connect a 2200pF capacitor from COMP1 to ground. See the <i>Soft-Start OUT1</i> section for more details.

System Power Management for Mobile Handset

Pin Description (continued)

PIN	NAME	FUNCTION
C1	LED3	Indicator LED Connection. Connect LED3 to the cathode of the precharge indicator LED. If a precharge indicator LED is not used, leave LED3 unconnected.
C2	LED2	25mA LED Current Regulator. Connect LED2 to the cathode of the second LED string.
C3	$\overline{\text{CHG}}$	Charger Disable Input. Connect $\overline{\text{CHG}}$ high to disable the charger, or low to enable the charger. Once the charger is enabled or disabled through I ² C, the state of $\overline{\text{CHG}}$ is ignored until reset.
C4	SDA	Data Input for Serial Interface. High impedance when the I ² C interface is off.
C5	LDO3	200mA LDO Output. Connect a 2.2 μ F capacitor from LDO3 to ground. In shutdown, LDO3 is pulled to ground through an internal 100 Ω .
C6	LDO2	200mA LDO Output. Connect a 2.2 μ F capacitor from LDO2 to ground. In shutdown, LDO2 is pulled to ground through an internal 100 Ω .
D1	SAFE_OUT	4.9V Regulated LDO Output with Input Overvoltage Protection. Connect a 1 μ F ceramic capacitor from SAFE_OUT to ground. SAFE_OUT can be used to supply low-voltage-rated USB systems and the precharge indicator.
D2	OUTVIB	Vibrator Driver Output. Connect OUTVIB to the vibrator motor. Connect a 1 μ F ceramic capacitor from OUTVIB to ground.
D3	$\overline{\text{IRQ}}$	Interrupt Request Open-Drain Output
D4	PWR_ON_CMP	Open-Drain Output to Wake Sleeping Baseband. PWR_ON_CMP pulses low while the charger is connected. See the PWR_ON_CMP section for details.
D5	LDO4	100mA LDO Output. Connect a 1 μ F capacitor from LDO4 to ground. In shutdown, LDO4 is pulled to ground through an internal 100 Ω .
D6	LDO1	400mA LDO Output. Connect a 4.7 μ F capacitor from LDO1 to ground. In shutdown, LDO1 is pulled to ground through an internal 50 Ω .
E1	CHG_IN	Charger Input Supply Voltage. CHG_IN is the power-supply input for the SAFE_OUT linear regulator and the battery charger. The operating range for the charger input is 4.1V to 10V. CHG_IN is protected up to 28V. When VCHG_IN exceeds 10.6V, SAFE_OUT and the charger are disabled. Connect a 1 μ F or larger ceramic capacitor from CHG_IN to ground.
E2	CHG_MON	Charge Current Monitoring Analog Output. CHG_MON outputs a voltage proportional to the charge current with 1.2V corresponding to the programmed fast-charge current. The CHG_MON output includes ripple from loads on the battery. If this is not desired, connect a small 0.01 μ F to 0.1 μ F capacitor at the input of the ADC to filter the ripple.
E3	INVIB	Input Supply for the Vibrator Driver. Connect INVIB to BATT. Connect a 1 μ F ceramic capacitor from INVIB to PGND.
E4	BATT	Battery Connection and IC Supply Voltage. Connect a 10 μ F ceramic capacitor from BATT to ground.
E5	AGND	Analog Ground. Connect PGND1, PGND2, and AGND to the PCB ground plane.
E6	REF	Reference Noise Bypass. Connect a 0.1 μ F ceramic capacitor from REF to AGND. Do not load. REF is high impedance when shut down.

System Power Management for Mobile Handset

MAX8939

Table 1. Output Summary

SUPPLY	OUTPUT RANGE	DEFAULT STATE AT POWER-UP	DEFAULT VALUE (V)	VOLTAGE TOLERANCE (%)	OUTPUT CURRENT (mA)	DESCRIPTION
LDO1	1.7V to 3.2V in 100mV step	Off	2.9	±3.0	400	Low-noise LDO to supply power either to the RF or analog section. LDO1 is controlled from the I ² C bus or the LDO1_EN input.
LDO2	1.7V to 3.2V in 100mV step	Off	1.8	±3.0	200	Low-noise LDO to supply power either to the RF or analog section. LDO2 is controlled from the I ² C bus.
LDO3	1.7V to 3.2V in 100mV step	Off	2.8	±3.0	200	Low-noise LDO to supply power either to the RF or analog section. LDO3 is controlled from the I ² C bus.
LDO4	1.7V to 3.2V in 100mV step	Off	2.8	±3.0	100	Low-noise LDO to supply power either to the RF or analog section. LDO4 is controlled from the I ² C bus.
OUT1 (STEP-UP)	3.5V to 5.0V in 100mV step	Off	5	±3.0	700	The OUT1 step-up converter provides a 5V power supply for an audio amplifier. The output voltage is programmable through I ² C.
OUT2 (LED)	V _{BATT} to 28V	Off	N/A	N/A	60	The OUT2 step-up converter operates at 2MHz and provides a high-voltage source for the keypad and backlight display drivers.
OUTVIB (Vibrator)	1.3V, 2.5V, 3V, or INVIB bypass	Off	3	±3.0	200	High-power vibrator driver with programmable output voltage and speed control in 70 steps through I ² C. The vibrator driver has active brake with stop.
Battery Charger	One-cell Li+ 3.6V, 4.15V, 4.20V, or 4.25V	N/A*	3.6	±0.6	90 default 1.3A (max)	A stand-alone constant-current, constant voltage (CC/CV), thermally regulated linear charger designed for charging a single-cell lithium-ion (Li+) battery. The charger current and protection timer is programmable through I ² C.
SAFE_OUT	4.9V	N/A*	4.9	±3.0	100 (max)	Protected output SAFE_OUT can be used to supply low-voltage-rated USB systems and the precharge indicator. The output voltage is a fixed 4.9V.

*Subject to valid voltage present at CHG_IN.

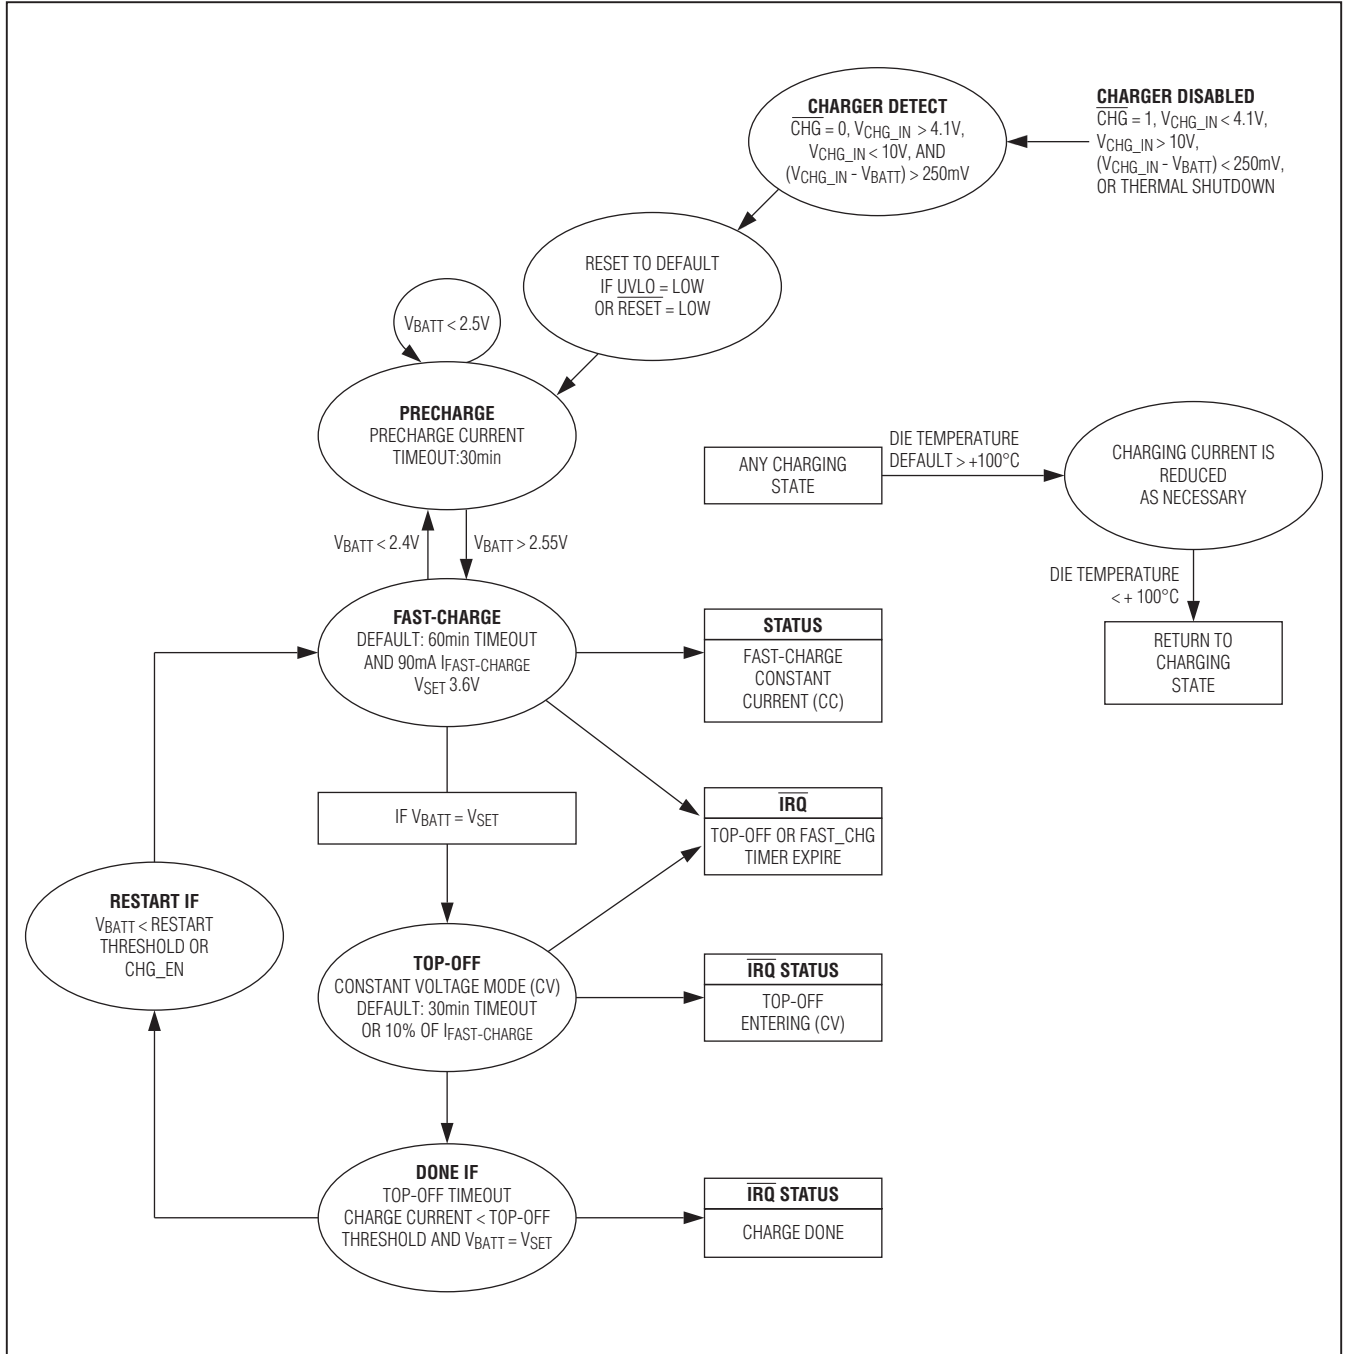

Figure 3. Battery Charger State Diagram

System Power Management for Mobile Handset

Detailed Description

Startup and Power States

To guarantee the correct startup of the MAX8939, an internal power-on reset is generated after the first connection of the battery. This resets the I²C registers to the default values. The MAX8939 is then in reset state. The reset state is a low power level, where the I²C interface is disabled and it is not possible to read or write to any register. The MAX8939 stays in reset state as long as V_{BATT} is below the UVLO upper threshold. When the battery voltage exceeds the UVLO upper threshold, the MAX8939 enters the standby state and the I²C bus can be written to. The typical response time of the UVLO detection is 50μs.

The UVLO upper threshold can be reached three ways:

- Fully charge battery is inserted and $\overline{\text{RESET}}$ is logic-high.
- $\overline{\text{RESET}}$ changes from logic-low to logic-high and $V_{\text{BATT}} > V_{\text{UVLO_UPPER}}$.
- Charger is detected and $\overline{\text{CHG}}$ is logic-low.

This temperature threshold can be programmed in register CHG_CONTROL_A.

Standby is a low-power state where the I²C is ready for read/write operations and enables the different power units (Table 1). If a unit is enabled through I²C or CHG_IN is powered, the bandgap and internal oscillator are started and the MAX8939 moves to the active state. The MAX8939 stays in the active state until the last unit (including the charger) is disabled.

Reset

The MAX8939 enters the reset state when the battery voltage drops below the UVLO lower threshold. In reset, all registers are reset except the STATUS and EVENT registers that retain their values as long as the battery is connected. In reset, all power units are disabled and only the UVLO and CHG_IN detection circuitry is active. If a fully charged battery is inserted or a charger is detected, the MAX8939 enters standby. If a valid charger is connected, the state machine enables the PWR_ON_CMP generator and an interrupt is sent to the host when above the UVLO upper threshold. When a valid charger is detected while in the reset state, the SAFE_OUT LDO is enabled and the charger begins pre-charging the battery.

The shutdown state is an extremely low-power state. To enter shutdown, hold $\overline{\text{RESET}}$ logic-low.

Shutdown

The shutdown state is an extremely low-power state. To enter shutdown, hold $\overline{\text{RESET}}$ logic-low.

In shutdown, all the internal blocks are disabled except the CHG_IN detection. If CHG_IN is asserted, the MAX8939 moves to the reset state and starts charging with the default settings. When entering from shutdown, the charger is reset and the PWR_ON_CMP generator is enabled. If the charger is removed, the MAX8939 moves back to the shutdown state if $\overline{\text{RESET}}$ is still logic-low.

Linear Regulators

The MAX8939 charger uses voltage, current and thermal-control loops to charge a single Li+ cell and to protect the battery. A complete charge cycle covers four states: prequalification (precharge), constant current fast-charge (CC), constant voltage top-off (CV), and charge complete (done). If the battery voltage is below 2.55V, the charger is pre-charging with 90mA until prequalification upper threshold is reached or the maximum precharge time (30min) reached. When the charger is in precharge mode, an LED indicator (LED3) and the SAFE_OUT LDO are turned on; all other functions are disabled.

Once the battery voltage has passed the prequalification upper threshold, the charger enters the fast-charge stage. An analog soft-start is used when entering fast charge to reduce inrush current on the input supply. When fast-charge is in progress, a safety timer is enabled and STATUS can be read out of register 0x02 bit 4. The fast-charge current and safety timer are programmable through the I²C interface. The default battery regulation voltage (V_{SET}) is 3.6V, but can be programmed to 4.15V, 4.2V, or 4.25V.

When the battery voltage reaches V_{SET}, the charger changes to top-off mode (CV). When entering top-off, an $\overline{\text{TRQ}}$ is flagged to indicate that the charger is in constant voltage mode. Top-off mode keeps the voltage constant and the current falls slowly until the top-off current threshold is reached. An $\overline{\text{TRQ}}$ is flagged to indicate charge is done. The top-off current threshold is a percentage of the fast-charge current, the threshold is programmable. When the top-off current threshold is set to 0% and restart is disabled, the top-off mode continues until the top-off timer expires. The top-off timer is programmable and can also be disabled. With the top-off threshold set to 0% and top-off timer disabled, the charger continuously charges the battery with a constant voltage and decreasing charge current. This makes it possible to control the charge algorithm through software, without influence of automatic maintaining charge.

System Power Management for Mobile Handset

To qualify charge as done, the current has to be below top-off current threshold or a timeout has occurred. To maintain the battery voltage, the charger can be programmed to restart once the battery voltage drops below a programmable threshold. When restart is enabled and the battery voltage drops below the restart threshold, the charger starts a new charging cycle by entering fast-charge.

If restart is disabled, the charger stops charging when done and does not maintain the battery voltage. When charge done occurs, an $\overline{\text{IRQ}}$ is sent to the host and a flag is set in register 0x03. Reading the register disables the charger. The charger can be enabled by writing to register 0x09 bit 0 (CHG_EN). If one of the safety timers (fast-charge or top-off) expires, an interrupt is sent to the host and a flag is set in register 0x03. The charger is disabled 5s after the safety times out.

If, at any point while charging the battery, the die temperature approaches the thermal regulation threshold (+100°C default), the MAX8939 reduces the charging current so that the die temperature does not this temperature. This feature not only protects the MAX8939 from overheating, but also allows the higher charge current without risking damage to the system.

Note all charger registers are reset to their default settings by power-on reset (POR) or $\overline{\text{RESET}}$.

Charger Disable ($\overline{\text{CHG}}$)

$\overline{\text{CHG}}$ is a logic input used to enable or disable the charger. Connect $\overline{\text{CHG}}$ high to disable the charger, or low to enable the charger. $\overline{\text{CHG}}$ operates when BATT is below its operating range and when BATT is valid, but prior to accessing the CHG_CONTROL_A register. Once the CHG_CONTROL_A register is accessed, either by reading or writing, the register CHG_CONTROL_A. CHG_EN bit controls the charger status and the state of $\overline{\text{CHG}}$ is ignored (although it still triggers an interrupt unless masked).

SAFE_OUT

SAFE_OUT is an LDO powered from the CHG_IN input. SAFE_OUT is enabled when a charger is detected ($4.1\text{V} < V_{\text{CHG_IN}} < 10\text{V}$) and provides a protected output regulated to 4.9V (5V max). Typically, SAFE_OUT is used to power low-voltage USB systems and the precharge indicator.

Indicator LED

The LED3 output sinks 3mA (typ) to drive an indicator LED. LED3 is on by default and can be controlled by the host by I²C (bit 7 of the REG_CONTROL register). Typically, this LED indicates charge status and SAFE_OUT powers the LED as shown in Figure 1.

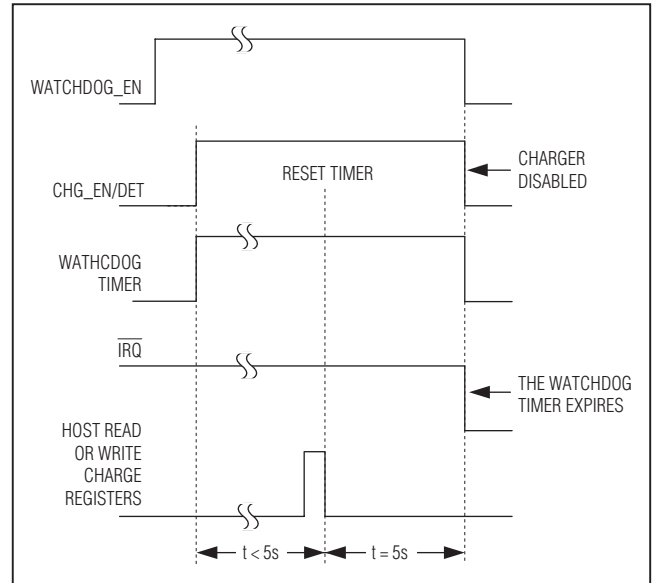

Figure 4. Watchdog Timing Diagram

Charge Current Monitor (CHG_MON)

CHG_MON is an analog output used to monitor the charge current. CHG_MON outputs a voltage proportional to the charge current with 1.2V corresponding to the programmed fast-charge current.

The CHG_MON output includes ripple from loads on the battery. If this is not desired, connect a small 0.01 μF to 0.1 μF capacitor at the input of the ADC to filter the ripple.

Charger Watchdog Timer

During battery fast-charge, a watchdog monitoring function can be activated to ensure that the host processor has control of the charge algorithm. The watchdog timer is enabled through register REG_CONTROL bit WD_EN. When the charger is enabled by CHG_EN or CHG_IN, the watchdog timer starts counting. Within 5s of enabling the charger, the host must read or write register 0x09 or 0x0A to indicate it is alive. This resets the watchdog timer and the host must continue to read or write register 0x09 or 0x0A in intervals of under 5s. If the host takes more than 5s for reading or writing these registers, the watchdog timer expires, generates an interrupt, flags the watchdog timeout in register 0x03, and disables the charger.

Linear Regulators

The MAX8939 includes four low-dropout linear regulators (LDOs). All LDOs are designed for low dropout, low noise, high PSRR, and low quiescent current to maximize battery life. When the battery voltage is above the UVLO upper threshold, the MAX8939 LDOs are ready to be

System Power Management for Mobile Handset

turned on through the I²C interface. The guaranteed current drive capabilities for the LDOs are 400mA for LDO1, 200mA for LDO2 and LDO3, and 100mA for LDO4. The output voltage for each LDO is programmable through the I²C interface from 1.7V to 3.2V in 0.1V steps.

LDO1 can be enabled through a hardware pin LDO1_EN. By connecting this pin to a logic-high level, the LDO enables automatically when the UVLO upper threshold is reached. The LDO can also be controlled by the LDO1_EN bit of the REG_CONTROL. When the LDO1_EN bit is written to, the LDO1 enable state reflects the value written, overriding the state of the LDO1_EN pin. When the state of the LDO1_EN pin changes, the LDO1 enable state is determined by the new state of the LDO1_EN pin, overriding the LDO1_EN bit value. This allows the system software to reduce quiescent power consumption by turning off LDO1 without impacting other logic that may utilize the same hardware control used for the LDO1_EN pin.

Interrupt Request (\overline{IRQ})

\overline{IRQ} is an active-low, open-drain output signal (requires an external pullup resistor) that indicates that an interrupt event has occurred and that the event and status information are available in the event/status registers. Such information includes temperature and voltages inside the MAX8939, fault conditions, etc. The event registers hold information about events that have occurred in the MAX8939. Events are triggered by a status change in the monitored signals. When an event bit is set in the event register, the \overline{IRQ} signal is asserted (unless \overline{IRQ} is masked by a bit in the IRQ mask register). The \overline{IRQ} is also masked during power-up and is not released until the event registers have been read. Each event register is reset to its initial condition after being read. The \overline{IRQ} is not released until all the event registers have been read. New events that occur during read-out of the event registers are held until all the event registers have been read to, ensuring that the host processor does not miss them.

PWR_ON_CMP

PWR_ON_CMP is an open-drain output used to wake-up a sleeping baseband. PWR_ON_CMP is activated when a charger is detected (V_{CHG_IN} is between 4.1V and 10V) and the battery voltage is above the UVLO threshold. If the battery has already reached the UVLO upper threshold, the charger is detected by a rising edge. When such an event is detected, the MAX8939 starts pulsing the PWR_ON_CMP output every 50ms, with a duty cycle of 98%. See Figure 5.

The event is also signaled by \overline{IRQ} , which is asserted when the UVLO upper threshold is reached and the CHG_DET bit is set in register 0x04 (bit 6). The MAX8939 continues pulsing PWR_ON_CMP until the EVENT registers are read, then the register is cleared and PWR_ON_CMP and \overline{IRQ} return to high impedance.

The events causing the PWR_ON_CMP activation are triggered by a rising edge signal that must remain valid for the duration of a 10ms debounce filter.

RESET_IN

RESET_IN is an active-low input signal to the MAX8939 and is used to provide a full system reset inside the MAX8939. As long as RESET_IN is asserted, the MAX8939 is not able to do anything (except the charger), until RESET_IN is released. All registers are cleared except the STATUS and EVENT registers. When RESET_IN is asserted, the EVENT_B bit RESET is set. If the CHG_IN voltage is valid and RESET_IN is asserted, the charger operates in its default state.

OUT1 Step-Up DC-DC Converter

OUT1 is a fixed-frequency PWM step-up converter. The converter switches an internal power MOSFET and synchronous rectifier at a constant 2MHz frequency with varying duty cycle up to 75% to maintain constant output voltage as the input voltage and load current vary.

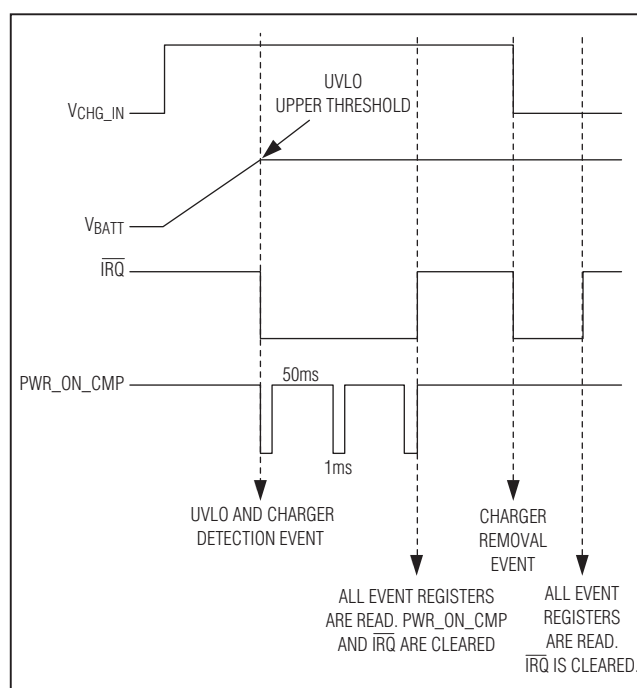

Figure 5. Wake-Up Sequence

System Power Management for Mobile Handset

Internal circuitry prevents any unwanted subharmonic switching in the critical step-down/step-up region by forcing a minimum 8% duty cycle.

OUT1 delivers up to 700mA to the load at a voltage programmable through I²C from 3.5V to 5V in 100mV steps.

Soft-Start OUT1

OUT1 soft-starts by charging CCOMP1 with a 100 μ A current source. During this time, the internal MOSFET is switching at the minimum duty cycle. Once VCOMP1 rises above 1V, the duty cycle increases until the output voltage reaches the desired regulation level. COMP1 is pulled to ground with a 30 Ω internal resistor during UVLO or shutdown.

OUT2 White LED Driver

OUT2 is the output from the step-up DC-DC converter for driving white LEDs. The converter is able to drive up to 60mA at up to 28V. The step-up converter is adaptive connected to the two low-dropout LED current regulators. The step-up converter operates at a fixed 2MHz switching frequency, enabling the use of very small external components to achieve a compact circuit area. For improved efficiency, the step-up converter automatically operates in pulse-skipping mode at light loads.

Soft-Start OUT2

From shutdown, once LED1 or LED2 is enabled through the I²C interface, the step-up converter prepares for soft-start. CCOMP2 is quickly pulled to 1V by an internal pullup clamp. Since the LED_ feedback node voltage is less than the regulation threshold (0.35V typ), 40 μ A current is sourced from the error amplifier and further charges CCOMP2. Once VCOMP2 reaches 1.25V, the step-up converter starts switching at a reduced duty cycle. As VCOMP2 rises, the step-up converter duty cycle increases.

When VLED1 or VLED2 reaches 0.35V (typ), the error amplifier stops sourcing current to CCOMP2, soft-start ends, and the control loop achieves regulation as VLED_ settles. The VCOMP2 where the step-up converter exits

soft-start depends on the load. A 2.5V upper limit to VCOMP2 is imposed to aid in transient recovery and to allow maximum output for low input voltages. CCOMP2 is discharged to ground through a 20k Ω internal resistor whenever the step-up converter is turned off, allowing the device to reinitiate soft-start when it is enabled.

LED1 and LED2 Current Regulators

Each current regulator drives a series string of LEDs. The maximum number of LEDs depends of maximum forward voltage of the LEDs at the maximum desired current. The total forward voltage of the LED string must be below 27.65V. The LED current is independently programmed using the I²C interface from 50 μ A to 25.25mA with a 128-step logarithmic dimming scheme.

Ramp-Up/Down

The MAX8939 LED current regulators provide ramp-up and ramp-down functionality for smooth transitions between different brightness settings. A controlled ramp is used when the LED current level is changed, and when the LEDs are enabled or disabled. LED1 and LED2 have individual ramp control, making it possible to ramp different groups at different rates. The ramp-up and ramp-down times are controlled by the LED_RU and LED_RD control bits, and the ramps are enabled/disabled by the LED_RAMP_EN bits. The MAX8939 increases or decreases the current one step every TRAMP/32 until the target LED current is reached.

Open/Short Detection

The MAX8939 includes comparators to detect open or shorted LEDs on LED1 and LED2. One comparator on each LED_ output detects when the voltage falls below 100mV, indicating an open LED fault. Another comparator on each LED_ output detects when the voltage rises above VOUT2 - 1V, indicating a shorted LED fault. The fault-detection comparators are enabled only when the corresponding LED_ current regulator is enabled and provides a continuous monitor of the current regulator conditions.

Figure 6. Ramp-Up/Ramp-Down

System Power Management for Mobile Handset

Once a fault is detected, it is flagged in the EVENT_B register and the IRQ signal is asserted (unless masked in the IRQ_MASK_B register).

Overvoltage Protection

If the voltage on the OUT2 rises above 28V (typ), the LED driver is put into the shutdown state. This protects the MAX8939 from excessive voltage in the event of an open-circuit LED.

Vibrator Driver

The vibrator driver is an LDO with PWM control (see Figure 7). The LDO output voltage is programmable through I²C to 1.3V, 2.5V, 3.0V, and V_{BATT}.

The vibrator driver is driven with a PWM signal of duty cycle from 0% to 83% or 100%, with a repetition frequency of 23.8kHz divided into 84 steps. A PWM ratio set to greater than 83 results in the vibrator output being permanently enabled (100%). Figure 8 shows the output waveform at different output voltage and PWM settings. The duty cycle is set by the I²C interface, with a value greater than 0 enabling the PWM mode of operation. By using the enable/disable, an active stop is activated. When the vibrator is disabled, an nFET switch turns on and shorts the vibrator to ground. At the same time the nFET switch works as a recovery diode to protect against reverse voltage from the vibrator.

The MAX8939 includes current protection that limits the current in case the vibrator motor locks up.

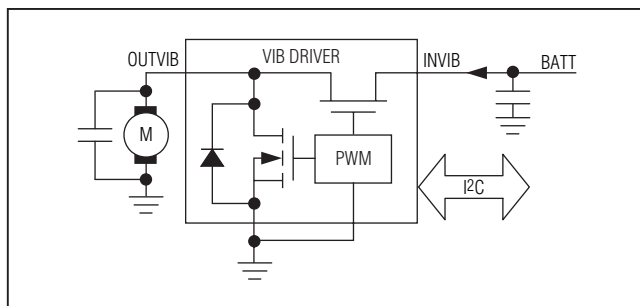

Figure 7. Vibrator Driver

Figure 8. Vibrator Driver PWM Output

Thermal Shutdown

The MAX8939 monitors the die temperature at the charger and each LDO and DC-DC regulator. When the temperature exceeds +160°C, the individual regulator is shutdown. Once the die cools by 20°C, the regulator may be reenabled through the I²C interface.

The charger has independent thermal control circuitry that lowers the charge current to regulate the die temperature during the charge.

I²C Serial Interface

The serial bus consists of a bidirectional serial-data line (SDA) and a serial-clock input (SCL). See Figure 9. The MAX8939 is a slave-only device, relying upon a master to generate the clock signal. The master initiates data transfer on the bus and generates SCL to permit data transfer. The I²C slave address is 0x62 for write operations and 0x63 for read operations.

I²C is an open-drain bus. SDA and SCL require pullup resistors (500Ω or greater). Optional (24Ω) resistors in series with SDA and SCL protect the IC inputs from high-voltage spikes on the bus lines. Series resistors also minimize crosstalk and undershoot on bus signals.

Data Transfer

One data bit is transferred during each SCL clock cycle. The data on SDA must remain stable during the high period of the SCL clock pulse (see Figure 10). Changes in SDA while SCL is high are control signals (see the START and STOP Conditions section for more information).

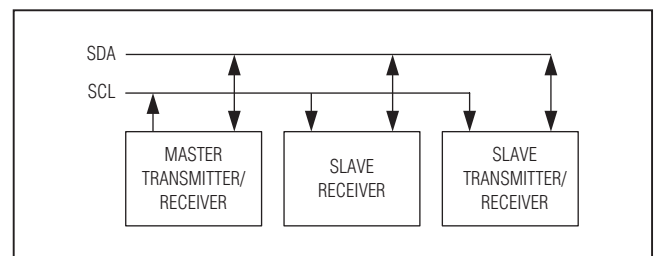

Figure 9. I²C Master/Slave Configuration

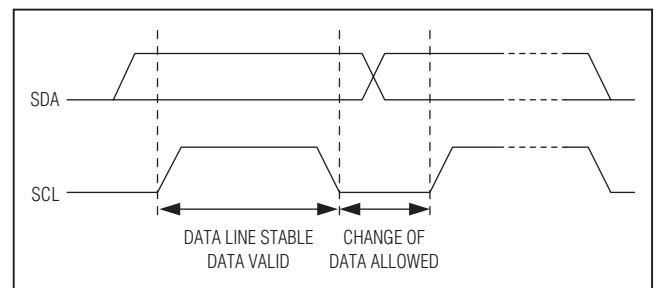

Figure 10. I²C Bit Transfer

System Power Management for Mobile Handset

Each transmit sequence is framed by a START (S) condition and a STOP (P) condition. Each data packet is 9 bits long; 8 bits of data followed by the acknowledge bit. The MAX8939 supports data transfer rates with SCL frequencies up to 400kHz.

START and STOP Conditions

When the serial interface is inactive, SDA and SCL idle high. A master device initiates communication by issuing a START condition. A START condition is a high-to-low transition on SDA with SCL high. A STOP condition is a low-to-high transition on SDA, while SCL is high (Figure 11).

A START condition from the master signals the beginning of a transmission to the MAX8939. The master terminates transmission by issuing a not acknowledge followed by a STOP condition (see the *Acknowledge* section for more information). The STOP condition frees the bus. To issue a series of commands to the slave, the master may issue REPEATED START (Sr) commands instead of a STOP command to maintain control of the bus. In general, a REPEATED START command is functionally equivalent to a regular start command.

When a STOP condition or incorrect address is detected, the MAX8939 internally disconnects SCL from the serial interface until the next START condition, minimizing digital noise and feedthrough.

Acknowledge

Both the master and the MAX8939 (slave) generate acknowledge bits when receiving data. The acknowledge bit is the last bit of each 9-bit data packet. To generate an acknowledge (A), the receiving device must pull SDA low before the rising edge of the acknowledge-related clock pulse (ninth pulse) and keep it low during the high period of the clock pulse (Figure 12). To generate a not acknowledge (NA), the receiving device allows SDA to be pulled high before the rising edge of the acknowledge-related clock pulse and leaves it high during the high period of the clock pulse.

Figure 11. I²C START and STOP Conditions

Monitoring the acknowledge bits allows for detection of unsuccessful data transfers. An unsuccessful data transfer occurs if a receiving device is busy or if a system fault has occurred. In the event of an unsuccessful data transfer, the bus master should reattempt communication at a later time.

Slave Address

A bus master initiates communication with a slave device (MAX8939) by issuing a START condition followed by the slave address. The slave address byte consists of 7 address bits (0110001) and a read/write bit (R/W). After receiving the proper address, the MAX8939 issues an acknowledge by pulling SDA low during the ninth clock cycle.

Write Operations

The MAX8939 recognizes the write byte protocol as defined in the SMBus™ specification and shown in section A of Figure 13. The write byte protocol allows the I²C master device to send 1 byte of data to the slave device. The write byte protocol requires a register pointer address for the subsequent write. The MAX8939 acknowledges any register pointer even though only a subset of those registers actually exists in the device. The write byte protocol is as follows:

- 1) The master sends a START command.
- 2) The master sends the 7-bit slave address followed by a write bit (0x62).
- 3) The addressed slave asserts an acknowledge by pulling SDA low.
- 4) The master sends an 8-bit register pointer.
- 5) The slave acknowledges the register pointer.
- 6) The master sends a data byte.
- 7) The slave updates with the new data.

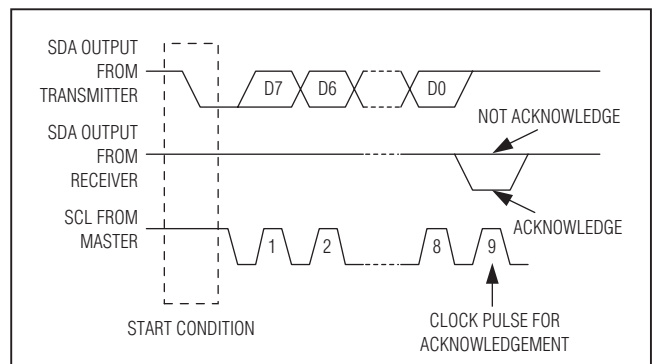

Figure 12. I²C Acknowledge

SMBus is a trademark of Intel Corp.

System Power Management for Mobile Handset

- 8) The slave acknowledges the data byte.
- 9) The master sends a STOP condition.

In addition to the write-byte protocol, the MAX8939 can write to multiple registers as shown in section B of Figure 13. This protocol allows the I²C master device to address the slave only once and then send data to a sequential block of registers starting at the specified register pointer.

Use the following procedure to write to a sequential block of registers:

- 1) The master sends a START command.
- 2) The master sends the 7-bit slave address followed by a write bit (0x62).
- 3) The addressed slave asserts an acknowledge by pulling SDA low.
- 4) The master sends the 8-bit register pointer of the first register to write.
- 5) The slave acknowledges the register pointer.
- 6) The master sends a data byte.
- 7) The slave updates with the new data.
- 8) The slave acknowledges the data byte.

- 9) Steps 6 to 8 are repeated for as many registers in the block, with the register pointer automatically incremented each time.
- 10) The master sends a STOP condition.

Read Operations

The method for reading a single register (byte) is shown in section A of Figure 14. To read a single register:

- 1) The master sends a START command.
- 2) The master sends the 7-bit slave address followed by a write bit (0x62).
- 3) The addressed slave asserts an acknowledge by pulling SDA low.
- 4) The master sends an 8-bit register pointer.
- 5) The slave acknowledges the register pointer.
- 6) The master sends a repeated START condition.
- 7) The master sends the 7-bit slave address followed by a read bit (0x063).
- 8) The slave asserts an acknowledge by pulling SDA low.
- 9) The slave sends the 8-bit data (contents of the register).
- 10) The master asserts a not acknowledge by keeping SDA high.
- 11) The master sends a STOP condition.

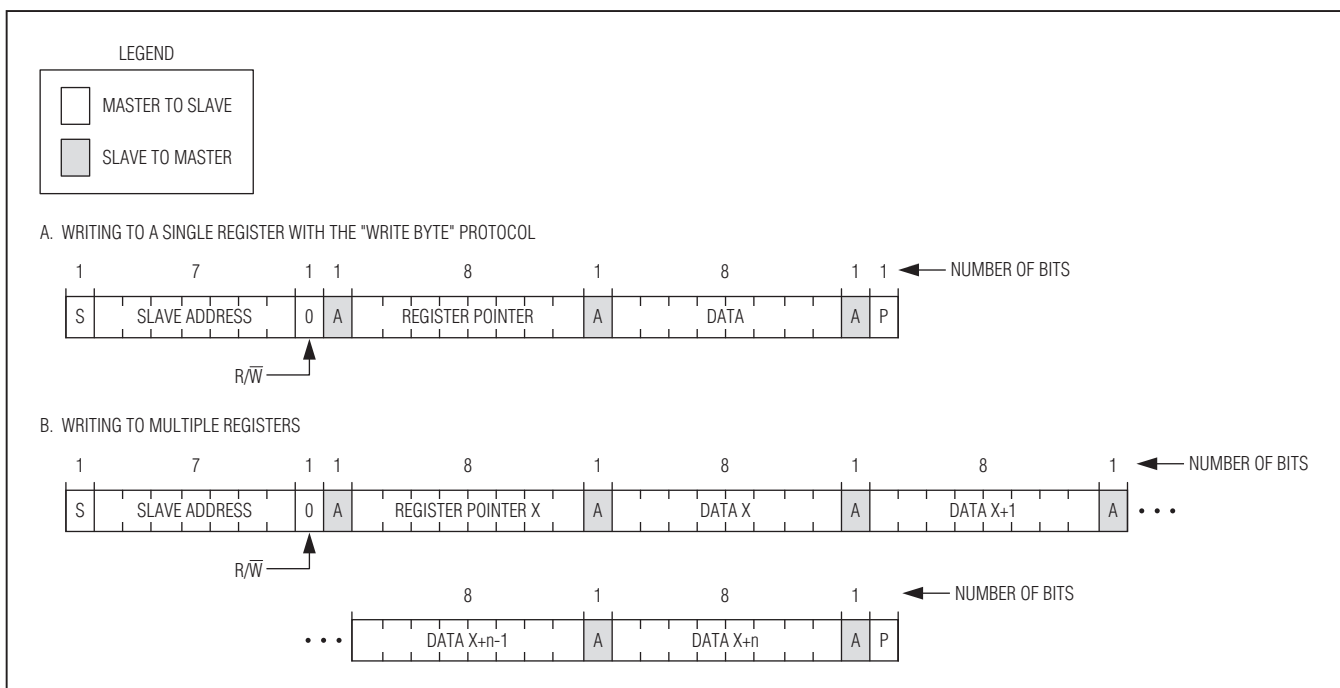

Figure 13. Writing to the MAX8939

System Power Management for Mobile Handset

In addition, the MAX8939 can read a block of multiple sequential registers as shown in section B of Figure 14. Use the following procedure to read a sequential block of registers:

- 1) The master sends a START command.
- 2) The master sends the 7-bit slave address followed by a write bit (0x62).
- 3) The addressed slave asserts an acknowledge by pulling SDA low.
- 4) The master sends an 8-bit register pointer of the first register in the block.
- 5) The slave acknowledges the register pointer.
- 6) The master sends a REPEATED START condition.
- 7) The master sends the 7-bit slave address followed by a read bit (0x063).
- 8) The slave asserts an acknowledge by pulling SDA low.
- 9) The slave sends the 8-bit data (contents of the register).
- 10) The master asserts an acknowledge by pulling SDA low when there is more data to read, or a not acknowledge by keeping SDA high when all data has been read.
- 11) Steps 9 and 10 are repeated for as many registers in the block, with the register pointer automatically incremented each time.
- 12) The master sends a STOP condition.

7	R&C	CHG_REM	Charger removal caused $\overline{\text{IRQ}}$	0

Note: The EVENT registers hold information about events that have occurred in MAX8939. Events are triggered by a change in the status registers, which contains the status of the monitored signals. When an EVENT bit is set in the event register the $\overline{\text{IRQ}}$ signal shall be asserted (unless the $\overline{\text{IRQ}}$ is to be masked by a bit in the $\overline{\text{IRQ}}$ mask register). The $\overline{\text{IRQ}}$ is also masked during the power-up sequence and are not released until the event registers have been read for the first time. The event registers are automatically cleared during read-out operation automatically. The event registers may be read-out in page mode. New events that occur during read-out are delayed before they are passed to the event register, ensuring that the host controller does not miss them.

System Power Management for Mobile Handset

Applications Information

Inductor Selection

The OUT1 step-up converter is designed to use a 2.2μH to 10μH inductor (see Table 22). To prevent core saturation, ensure that the inductor saturation current rating exceeds the peak inductor current for the application. Calculate the worst-case peak inductor current with the following formula:

$$I_{PEAK} = \frac{V_{OUT} \times I_{OUT(MAX)}}{0.9 \times V_{IN(MIN)}} + \frac{V_{IN(MIN)} \times 0.5\mu s}{2 \times L}$$

The OUT2 LED driver is optimized for using a 10μH inductor, although larger or smaller inductors may be used. Using a smaller inductance results in discontinuous current mode operation over a larger range of output power, whereas use of a larger inductance results in continuous conduction for most of the operating range.

To prevent core saturation, ensure that the inductor's saturation current rating exceeds the peak inductor current for the application. For larger inductor values and continuous conduction operation, calculate the worst-case peak inductor current with the following formula:

$$I_{PEAK} = \frac{V_{OUT} \times I_{OUT(MAX)}}{0.9 \times V_{IN(MIN)}} + \frac{V_{IN(MIN)} \times 0.5\mu s}{2 \times L}$$

For small values of L in discontinuous conduction operation, I_{PEAK} is 860mA (typ). Table 23 provides a list of recommended inductors.

Capacitor Selection

Ceramic capacitors are recommended due to their low ESR. Ensure that the capacitor maintains its capacitance over temperature and DC bias. Generally ceramic capacitors with X5R or X7R temperature characteristics perform well. Note that some small size ceramic capacitors fail to maintain their capacitance when a DC bias is applied and should be avoided. Place the capacitors as close as possible to the IC.

The recommended input and output capacitor values are shown in Figure 1, however, larger value capacitors can be used to further reduce ripple at the expense of size and higher cost.

Compensation

The OUT1 step-up converter is compensated for stability through an external compensation network from COMP1 to ground. A 2200pF ceramic capacitor is recommended.

The OUT2 LED driver is compensated for stability through an external compensation network from COMP2 to ground. A 0.22μF ceramic capacitor is recommended for most applications. Higher C_{COMP2} values increase soft-start duration, as well as the time delay between enabling the step-up converter to initiating soft-start. See the *Soft-Start OUT2* section for more information.

System Power Management for Mobile Handset

MAX8939

Diode Selection

The OUT2 LED converter uses an external rectifier diode. A Schottky diode is recommended due to its fast recovery time and low forward voltage drop. Ensure that the diode's average and peak current rating exceeds the average output current and peak inductor current. In addition, the diode's reverse breakdown voltage must exceed the maximum V_{OUT2} .

PCB Layout

Due to fast switching waveforms and high current paths, careful PCB layout is required. Minimize trace lengths between the IC and the inductor, the diode, the input capacitor, and the output capacitor. Minimize trace

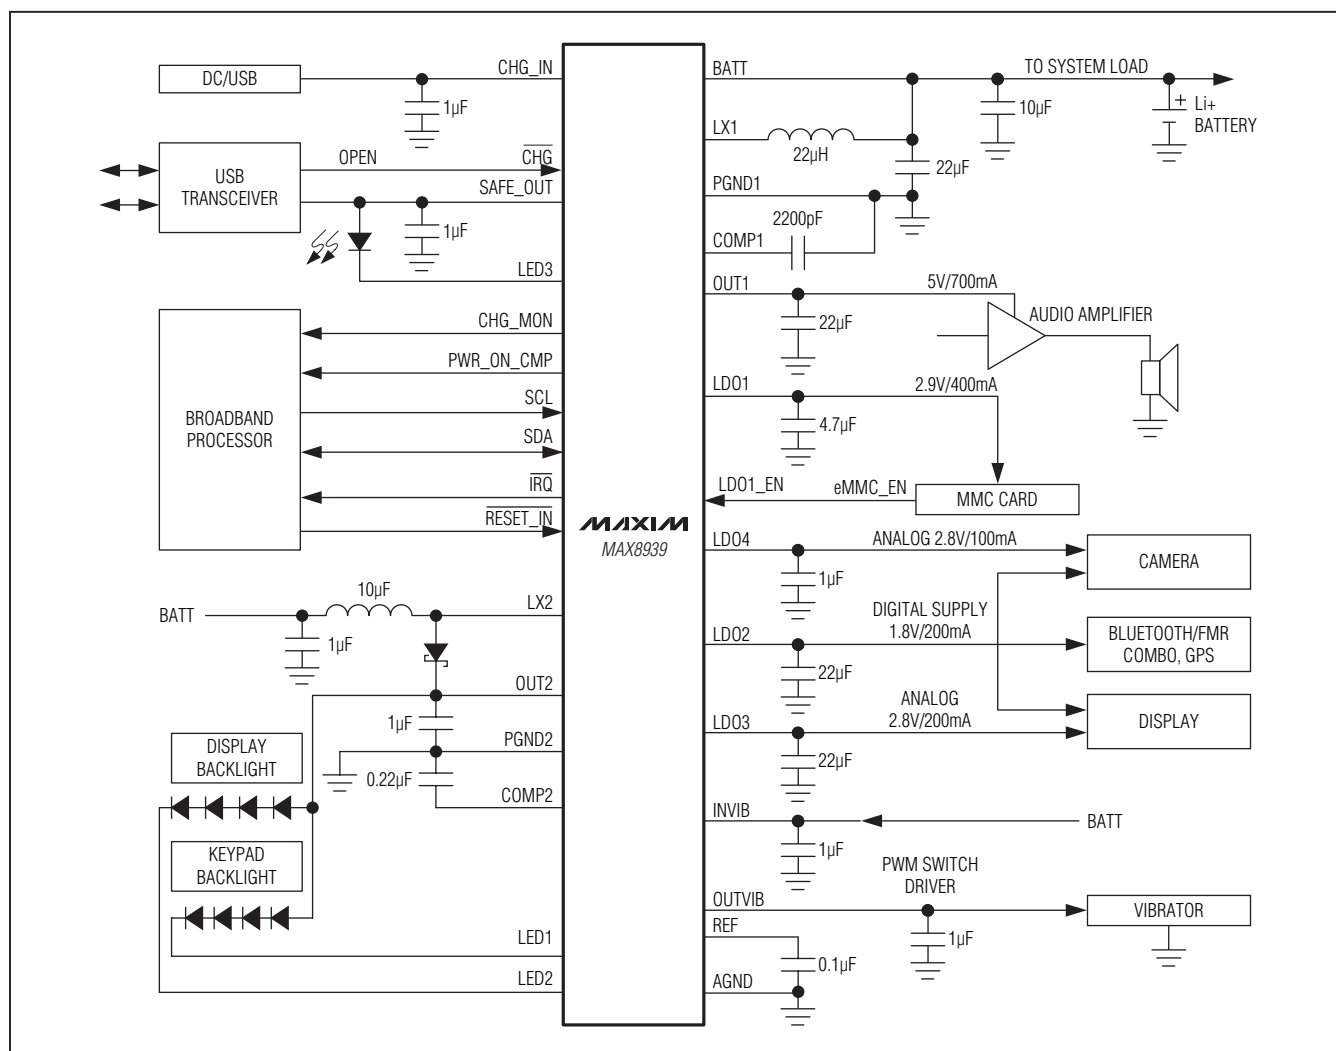

lengths between the input and output capacitors and the MAX8939 ground terminal, and place input and output capacitor grounds as close together as possible. Use separate power ground and analog ground copper areas, and connect them together at the output capacitor ground. Keep traces short, direct, and wide.

Keep noisy traces, such as the LX_{-} node trace, away from sensitive analog circuitry. For improved thermal performance, maximize the copper area of the LX_{-} and $PGND_{-}$ traces. Refer to the MAX8939 Evaluation Kit for an example layout.
