## 3-in-1 Silicon Delay Line

MXD1013

### General Description

The MXD1013 contains three independent, monolithic, logic-buffered delay lines with delays ranging from 10ns to 200ns. Nominal accuracy is  $\pm 2$ ns for a 10ns to 60ns delay,  $\pm 3\%$  for a 70ns to 100ns delay, and  $\pm 5\%$  for a 150ns to 200ns delay. Relative to hybrid solutions, these devices offer enhanced performance and higher reliability, and reduce overall cost. Each output can drive up to ten standard 74LS loads.

The MXD1013 is available in multiple versions, each offering a different combination of delay times. It comes in the space-saving 8-pin  $\mu$ MAX package, as well as a standard 8-pin SO and DIP. It is also offered in industry-standard 16-pin SO and 14-pin DIP packaging, allowing full compatibility with the DS1013 and other delay-line products.

## TIMING CHARACTERISTICS

**Note 1:** Specifications to -40°C are guaranteed by design, not production tested.

**Note 2:** All voltages referenced to GND.

**Note 3:** Measured with outputs open.

**Note 4:** Guaranteed by design.

**Note 5:** Pulse width and/or period specifications may be exceeded, but accuracy is application sensitive (i.e., layout, decoupling, etc.).

**Note 6:** V<sub>CC</sub> = +5V at +25°C. Typical delays are accurate on both rising and falling edges within ±2ns for delays from 10ns to 60ns, within ±3% for delays from 70ns to 100ns, and within ±5% for delays from 150ns to 200ns.

**Note 7:** The *Part Number and Delay Times* table provides typical delays at +25°C with V<sub>CC</sub> = +5V. The delays may shift with temperature and supply variations. The combination of temperature (from +25°C to 0°C, or +25°C to +70°C) and supply variation (from 5V to 4.75V, or 5V to 5.25V) could produce an additional typical delay of ±1.5ns or ±3%, whichever is greater.

**Note 8:** All output delays tend to vary unidirectionally with temperature or supply voltage variations (i.e., if OUT1 slows down, all other outputs also slow down).

### Definitions of Terms

**Period:** The time elapsed between the first pulse's leading edge and the following pulse's leading edge.

**Pulse Width ( $t_{WI}$ ):** The time elapsed on the pulse between the 1.5V level on the leading edge and the 1.5V level on the trailing edge, or vice versa.

**Input Rise Time ( $t_{RISE}$ ):** The elapsed time between the 20% and 80% points on the input pulse's leading edge.

**Input Fall Time ( $t_{FALL}$ ):** The time elapsed between the 80% and 20% points on the input pulse's trailing edge.

**Time Delay, Rising ( $t_{PLH}$ ):** The time elapsed between the 1.5V level on the input pulse's leading edge and the corresponding output pulse's leading edge.

**Time Delay, Falling ( $t_{PHL}$ ):** The time elapsed between the 1.5V level on the input pulse's trailing edge and the corresponding output pulse's trailing edge.

### Test Conditions

Ambient Temperature:	+25°C
Supply Voltage ( $V_{CC}$ ):	5.0V $\pm$ 0.1V
Input Pulse:	High = 3.0V $\pm$ 0.1V Low = 0.0V $\pm$ 0.1V
Source Impedance:	50 $\Omega$ max
Rise and Fall Times:	3.0ns max
Pulse Width:	500ns max
Period:	1 $\mu$ s

Each output is loaded with a 74F04 input gate. Delay is measured at the 1.5V level on the rising and falling edges. The time delay due to the 74F04 is subtracted from the measured delay.

## Applications Information

### Supply and Temperature Effects on Delay

Over the specified range, the MXD1013's delays are typically 2% accurate. Variations in supply voltage may affect the MXD1013's fixed output delays. Supply voltages beyond the specified range may result with larger variations. Although there might be a slight variance in delays over temperature, the MXD1013 is internally compensated to maintain its nominal values.

### Loading Effect on Delay Lines

Capacitive loads increase delay times as they increase the rise and fall times of the delay lines. Other logic devices increase the capacitance at the output of the delays, which can affect device performance.

### Board Layout Considerations

Bypass the MXD1013 with a 0.1μF capacitor to minimize the impact of high-speed switching on the power supply. The power supply must be able to deliver the required switching currents for proper operation.

It is advisable to minimize trace lengths in order to reduce board capacitance as well as the traveling distance between devices. Sockets and wire-wrapped boards increase capacitance and should be avoided.
