FUNCTIONAL DESCRIPTION

The LH521002A is a high speed 1M-bit static RAM organized as 256K $\times$ 4. A fast, efficient design is obtained with a CMOS periphery and a matrix constructed with polysilicon load memory cells.

This RAM is fully static in operation. The Chip Enable ($\bar{E}$) reduces power to the chip when $\bar{E}$ is HIGH. Standby power drops to its lowest level when $\bar{E}$ is raised to within 0.2 V of V_{CC} .

Write cycles occur when both $\bar{E}$ and Write Enable ($\bar{W}$) are LOW. Data is transferred from the DQ pins to the memory location specified by the 18 address lines.

Read cycles occur when $\bar{E}$ is LOW and $\bar{W}$ is HIGH. A Read cycle will begin upon an address transition, on a falling edge of $\bar{E}$, or on a rising edge of $\bar{W}$.

High frequency design techniques should be employed to obtain the best performance from this device. Solid, low impedance power and ground planes, with high frequency decoupling capacitors, are desirable. Series termination of the inputs should be considered when transmission line effects occur.

DATA RETENTION TIMING

$\bar{E}$ must be held above the lesser of V_{IH} or V_{CC} – 0.2 V to prevent improper operation when V_{CC} < 4.5 V. $\bar{E}$ must be V_{CC} – 0.2 V or greater to meet I_{DR} specification. All other inputs are 'Don't Care.'

TIMING DIAGRAMS – READ CYCLE

Read Cycle No. 1

Chip is in Read Mode: $\overline{W}$ is HIGH, $\overline{E}$ and $\overline{G}$ are LOW. Read cycle timing is referenced from when all addresses are stable until the first address transition. Crosshatched portion of DQ implies that data lines are in the Low-Z state and the data may not be valid.

Read Cycle No. 2

Chip is in Read Mode: $\overline{W}$ is HIGH. Timing illustrated for the case when addresses are valid while $\overline{E}$ goes LOW. Data Out is not specified to be valid until t_{EA} , but may become valid as soon as t_{ELZ} . Outputs will transition from High-Z to Valid Data Out. Data Out is valid after both t_{EA} and t_{GA} are met.

Figure 5. Read Cycle No. 1

Figure 6. Read Cycle No. 2

TIMING DIAGRAMS – WRITE CYCLE

Addresses must be stable during Write cycles. $\bar{E}$ or $\bar{W}$ must be HIGH during address transitions. The outputs will remain in the High-Z state if $\bar{W}$ is LOW when $\bar{E}$ goes LOW. Care should be taken so that the output drivers are disabled prior to placing the Input Data on the DQ lines. This will prevent bus contention, reducing system noise.

Write Cycle No. 1 ($\bar{W}$ Controlled)

Chip is selected: $\bar{E}$ and $\bar{G}$ are LOW. Using only $\bar{W}$ to control Write cycles may not offer the best device performance, since both t_{WHZ} and t_{DW} timing specifications must be met.

Write Cycle No. 2 ($\bar{E}$ Controlled)

$\bar{G}$ is LOW. DQ lines may transition to Low-Z if the falling edge of $\bar{W}$ occurs after the falling edge of $\bar{E}$.
