LDM12-XX-XXX

Miniature, Wide Input Constant Current DC/DC LED Drivers

Input

Electrical Specifications Specifications typical @ +25°C, nominal input voltage & rated output current, unless otherwise noted. Specifications subject to change without notice.

Key Features:

Constant Current Output

- Wide 7V to 16V Input Range
- 93% Efficiency
- Miniature MiniDIP Case
- 300 mA to 1A Output
- Meets EN 60950
- 3.3 MHrs MTBF
- Digital & Analog Dimming!

Notes:

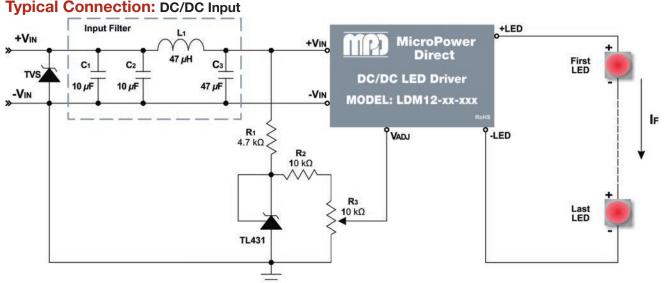

1.

A reversed power source could damage the unit. No connection should be made between input ground and the output.

These are step-down devices, the maximum output open voltage is 3. equal to the input voltage.

The VabJ input should be left open if not used. Grounding VabJ will shut the unit down. Connecting VabJ to Vin may damage the unit.

5. Exceeding the specified maximum output power could cause damage to the unit.

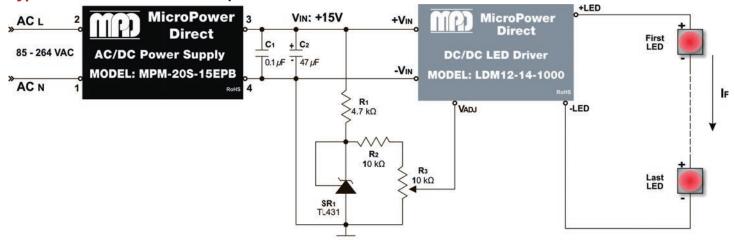

Connection Notes:

To comply with EN61000-4-5, a TVS should be installed before the input filter components. A 3.0SMCJ15A or SMCJ16A is recommended. The TVS max clamping voltage (@max peak pulse current Vc) must be ≤20V. This will prevent any surge from exceeding the maximum input of the driver (20 VDC). Exceeding the maximum input rating could damage the driver.

The filter shown (C1, C2, C3 and L1) will help to meet conducted emission requirements. With the addition of the filter, the unit should meet the levels of EN 55015.

Typical Connection: AC/DC Input

Connection Notes:

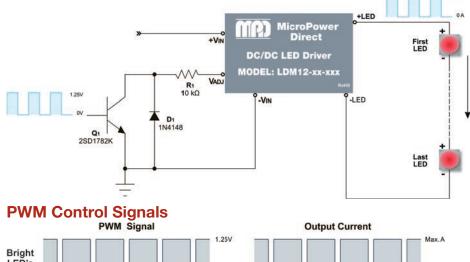

This is a distributed (or two-stage) AC connection. In this configuration, the AC line in (85 to 264 VAC) is connected to the MPM-20S-15EPB, a compact 20W AC/DC power supply. The MPM-20S-15EPB provides a tightly regulated 15 VDC output at 1,330 mA. The 15 VDC output powers the LED driver.

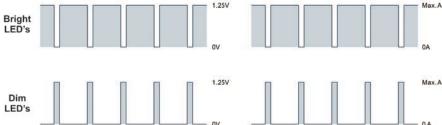

The two stage approach can simplify the safety approval process (most AC/DC power supplies on the market are approved to EN 60950) and may increase design flexibility. Besides the output voltage/current ratings, other specifications to consider when selecting the input AC/DC supply might include input range, case size, efficiency, EMI ratings and operating temperature range.

Note: The output current adjustment circuit shown in both connection diagrams is discussed on page 4.

PWM Output Current Control

www.micropowerdirect.com

An LED operates at its maximum efficiency when operated at the rated drive current specified by the manufacturer. Operating an LED at lower than its rated forward current not only decreases the system efficiency; but may cause color (or wavelength) shifting. In illumination applications, this could cause visible changes to lighting.

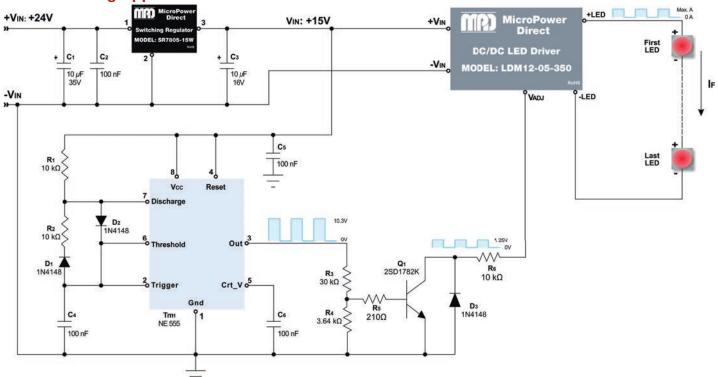

IF A preferred method is using pulse width modulation (PWM). As shown at left, the output current is adjusted by applying a PWM signal to the VADJ input. By varying the signal duty cycle the average output current is adjusted up or down. To avoid visible flicker, the PWM signal should be greater than 200 Hz.

For duty cycles (DPWM) between 0.1 and 1, the output current is derived by the formula:

$I_{NOM} = I_{MAX} X D_{PWM}$

The VADJ input may be driven via an open collector transistor (as shown). The diode and resistor suppress high amplitude negative spikes that may be caused by the drain-source capacitance of the transistor. Negative spikes on the control input of the unit could cause errors in output current or erratic operation.

The VADJ input can also be driven by the open drain output of a microcontroller. Again, any high amplitude negative spikes that may be caused by the drainsource capacitance of the FET must be supressed.

A simple method of achieving digital (or PWM) dimming is by using a 555 timer to apply a series of pulses to the VADJ input, as illustrated above. The 555 operates over a supply voltage range of 4.5 VDC to 18VDC. Here it is connected to the 15 VDC output of the **SR7805** switching regulator (this is also the VIN of the LED driver). Care should be taken to minimize ripple at the Vcc input. Excess ripple could cause timing errors.

The timer is connected for astable (free run) operation. The frequency is set by R1, R2 and C4. The timing capacitor (C4) charges through R1 and D2. When it reaches the level of $^{2}\!/_{3}$ Vcc, the discharge pin (pin 7) goes low and C4 will discharge through D1 and R2 to the internal discharge transistor. When the C4 voltage drops to $^{1}\!/_{3}$ Vcc, the discharge pin goes high and C4 begins to charge

again. The formulas for calculating the frequency and duty cycle are included in the MPD application note "*Driving LEDs*".

The diodes (D₁ and D₂) allow duty cycles below 50% to be set. Diode D₁ bypasses R₂ while C₄ is charging. Diode D₂ is optional (but recommended), essentially blocking R₂ during the charge period. Theoretically, this circuit will allow for duty cycles over a range of approximately 5% to 95%. If manual adjustment is desired, a potentiometer may be substituted for R₂ (with some adjustment of the circuit).

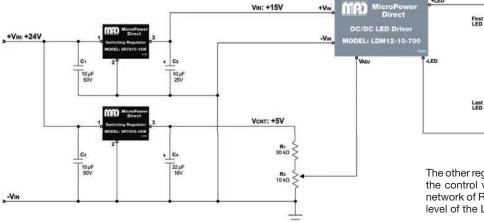

The size of C4 is generally not critical, but it should be as low leakage as possible. In order to avoid excessive current flow through the internal discharge transistor, it is recommended that R1 be at least 5 k Ω .

PWM Dimming Application

Analog Output Current Control (VCNT = 5V)

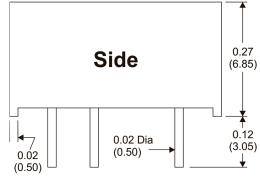

www.micropowerdirect.com

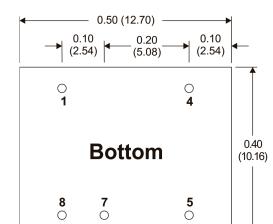

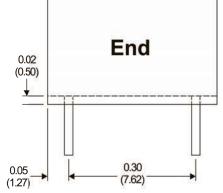

Analog Output Current Control (5 - 16 VDC IN)

Mechanical Dimensions

The output current of the unit can also be set by adjusting the voltage level on the VADJ input to a value between 0.3V to 1.25V (IOUT will vary from 25% to 100% of rated output current). Care must be taken not to exceed 1.25V on this input, or the driver may be damaged.

A simple analog circuit using two low cost, switching regulators is shown at left. Working from inputs that can range from 20 to 32 VDC, the top regulator (SR1) keeps the input to the LED driver at 15 VDC.

The other regulator (SR2), driven off the same input line maintains the control voltage (for the VADJ input) at 5 VDC. The resister network of R1 and R2 can now be used to set the output current level of the LED driver. This level is equal to:

$V_{ADJ} = \frac{R_2}{R_1 + R_2} X V_{CTRL}$

In the second circuit, the 5 VDC regulator (SR₂) is replaced by the shunt regulator (D1) circuit connected in parallel with the resistor network. The regulator will maintain the voltage across R2 and R3 at 2.5 VDC, insuring that the 1.25 VDC limit on the VADJ pin will not be exceeded.

When using the analog control input, the nominal output current is equal to:

 $I_{\text{NOM}} = I_{\text{MAX}} \times \frac{V_{\text{ADJ}}}{1.25}$

The VADJ input should be left open if not used. Grounding VADJ will shut the unit down. Connecting VADJ to directly to +VIN may damage the unit.
