Description

M2Y1G64TU88G7B and M2Y2G64TU8HG5B are 240-Pin Double Data Rate 2 (DDR2) Synchronous DRAM Unbuffered Dual In-Line Memory Module (UDIMM), organized as one rank 128Mx64 and two ranks 256Mx64 high-speed memory array. M2Y1G64TU88G7B uses eight 128Mx8 DDR2 SDRAMs and M2Y2G64TU8G5B uses sixteen 128Mx8 DDR2 SDRAMs in BGA packages. These DIMMs are manufactured using raw cards developed for broad industry use as reference designs. The use of these common design files minimizes electrical variation between suppliers. All Elixir DDR2 SDRAM DIMMs provide a high-performance, flexible 8-byte interface in a 5.25” long space-saving footprint.

The DIMM is intended for use in applications operating up to 333MHz (or 400MHz/533MHz) clock speeds and achieves high-speed data transfer rates of up to 667Mbps (or 800Mbps/1066Mbps). Prior to any access operation, the device $\overline{CAS}$ latency and burst / length /operation type must be programmed into the DIMM by address inputs A0-A13 and I/O inputs BA0, BA1 and BA2 using the mode register set cycle.

The DIMM uses serial presence-detect implemented via a serial 2,048-bit EEPROM using a standard IIC protocol. The first 128 bytes of serial PD data are programmed and locked during module assembly. The remaining 128 bytes are available for use by the customer.

Input/Output Functional Description

Symbol	Type	Polarity	Function
CK0, CK1, CK2	(SSTL)	Positive Edge	The positive line of the differential pair of system clock inputs which drives the input to the on-DIMM PLL. All the DDR2 SDRAM address and control inputs are sampled on the rising edge of their associated clocks.
$\overline{CK0}$, $\overline{CK1}$, $\overline{CK2}$	(SSTL)	Negative Edge	The negative line of the differential pair of system clock inputs which drives the input to the on-DIMM PLL.
CKE0, CKE1	(SSTL)	Active High	Activates the SDRAM CK signal when high and deactivates the CK signal when low. By deactivating the clocks, CKE low initiates the Power Down mode, or the Self Refresh mode. CKE1 apply on 2GB UDIMM only.
$\overline{CS0}$, $\overline{CS1}$	(SSTL)	Active Low	Enables the associated SDRAM command decoder when low and disables the command decoder when high. When the command decoder is disabled, new commands are ignored but previous operations continue. $\overline{CS1}$ apply on 2GB UDIMM only.
$\overline{RAS}$, $\overline{CAS}$, $\overline{WE}$	(SSTL)	Active Low	When sampled at the positive rising edge of the clock, $\overline{RAS}$, $\overline{CAS}$, $\overline{WE}$ define the operation to be executed by the SDRAM.
V_{REF}	Supply		Reference voltage for SSTL-18 inputs
V_{DDQ}	Supply		Isolated power supply for the DDR SDRAM output buffers to provide improved noise immunity
ODT0, ODT1	Input	Active High	On-Die Termination control signals. ODT1 apply on 2GB UDIMM only.
BA0 – BA2	(SSTL)	-	Selects which SDRAM bank is to be active.
A0 - A9 A10/AP A11 - A13	(SSTL)	-	During a Bank Activate command cycle, A0-A13 defines the row address (RA0-RA13) when sampled at the rising clock edge. During a Read or Write command cycle, A0-A9 defines the column address (CA0-CA9) when sampled at the rising clock edge. In addition to the column address, AP is used to invoke “Autoprecharge” operation at the end of the Burst Read or Write cycle. If AP is high, Autoprecharge’s selected and BA0/BA1 defines the bank to be precharged. If AP is low, autoprecharge is disabled. During a Precharge command cycle, AP is used in conjunction with BA0/BA1 to control which bank(s) to precharge. If AP is high all 4 banks will be precharged regardless of the state of BA0/BA1. If AP is low, then BA0/BA1 are used to define which bank to pre-charge.
DQ0 – DQ63	(SSTL)	Active High	Data and Check Bit Input /Output pins.
V_{DD}, V_{SS}	Supply		Power and ground for the DDR2 SDRAM input buffers and core logic
DQS0 – DQS8 $\overline{DQS0}$ – $\overline{DQS8}$	(SSTL)	Negative and Positive Edge	Data strobe for input and output data
DM0 – DM8	Input	Active High	The data write masks, associated with one data byte. In Write mode, DM operates as a byte mask by allowing input data to be written if it is low but blocks the write operation if it is high. In Read mode, DM lines have no effect. DM8 is associated with check bits CB0-CB7, and is not used on x64 modules.
SA0 – SA2		-	Address inputs. Connected to either V_{DD} or V_{SS} on the system board to configure the Serial Presence Detect EEPROM address.
SDA		-	This bi-directional pin is used to transfer data into or out of the SPD EEPROM. A resistor must be connected from the SDA bus line to V_{DD} to act as a pull-up.
SCL		-	This signal is used to clock data into and out of the SPD EEPROM. A resistor may be connected from the SCL bus time to V_{DD} to act as a pull-up.
V_{DDSPD}	Supply		Serial EEPROM positive power supply.

Symbol	Parameter	Rating	Units
V_{IN}, V_{OUT}	Voltage on any pin relative to Vss	-0.5 to 2.3	V
V_{DDQ}	Voltage on V_{DDQ} supply relative to Vss	-0.5 to 2.3	V
V_{DDQL}	Voltage on V_{DDQL} supply relative to Vss	-0.5 to 2.3	V
