# 3.75 kV, 7-Channel, SPIsolator Multiple Slave, Digital Isolator for SPI 

## Data Sheet

## FEATURES

Supports up to 17 MHz SPI clock speed
4 high speed, low propagation delay, SPI signal isolation channels
Supports up to 4 slave devices
20-lead SSOP package with 5.1 mm creepage
High temperature operation: $125^{\circ} \mathrm{C}$
High common-mode transient immunity: > $\mathbf{2 5} \mathbf{k V} / \mu \mathrm{s}$
Safety and regulatory approvals
UL recognition per UL 1577
3750 V rms for 1 minute
CSA Component Acceptance Notice 5A
VDE certificate of conformity DIN V VDE V 0884-10 (VDE V 0884-10):2006-12
$V_{\text {IORM }}=565$ V peak

## APPLICATIONS

Industrial programmable logic controllers (PLCs) Sensor isolation

## GENERAL DESCRIPTION

The ADuM3154 ${ }^{1}$ is an SPIsolator ${ }^{\text {mw }}$ digital isolator optimized for a serial peripheral interface (SPI) that includes support for up to four slave devices. Based on the Analog Devices, Inc., $i$ Coupler ${ }^{\circledR}$ chip scale transformer technology, the low propagation delay and jitter in the CLK, MO/SI, MI/SO, and SS SPI bus signals support SPI clock rates of up to 17 MHz .
The ADuM3154 isolator also provides a slave select multiplexing system that allows up to four slave devices to be serviced from one isolator. When a target slave is selected, the slave select signal propagates to the desired output with low propagation delay, allowing tight timing control. The isolated SSx is addressed through a 250 kbps low speed, 2 -channel address bus, allowing the target slave device to be changed in as little as $2.5 \mu \mathrm{~s}$.

## SPECIFICATIONS

## ELECTRICAL CHARACTERISTICS—5 V OPERATION

All typical specifications are at $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ and $\mathrm{V}_{\mathrm{DD} 1}=\mathrm{V}_{\mathrm{DD} 2}=5 \mathrm{~V}$. Minimum and maximum specifications apply over the entire recommended operation range: $4.5 \mathrm{~V} \leq \mathrm{V}_{\mathrm{DD} 1} \leq 5.5 \mathrm{~V}, 4.5 \mathrm{~V} \leq \mathrm{V}_{\mathrm{DD} 2} \leq 5.5 \mathrm{~V}$, and $-40^{\circ} \mathrm{C} \leq \mathrm{T}_{\mathrm{A}} \leq+125^{\circ} \mathrm{C}$, unless otherwise noted. Switching specifications are tested with $\mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}$ and CMOS signal levels, unless otherwise noted.

${ }^{1} V_{D D x}=V_{D D 1}$ or $V_{D D 2}$.
${ }^{2} \mathrm{~V}_{\text {INPUT }}$ is the input voltage of any of the MCLK, $\overline{\mathrm{MSS}}, \mathrm{MO}, \mathrm{SO}, \mathrm{SSAO}$, or SSA1 pins.
${ }^{3}$ loutput is the output current of any of the SCLK, $\mathrm{MI}, \mathrm{SI}, \mathrm{SS} 0, \mathrm{SS} 1, \mathrm{SS} 2$, or SS 3 pins.
${ }^{4}|\mathrm{CM}|$ is the maximum common-mode voltage slew rate that can be sustained while maintaining output voltages within the $V_{\text {OH }}$ and $V_{O L}$ limits. The common-mode voltage slew rates apply to both rising and falling common-mode voltage edges.

ADuM3154

## ELECTRICAL CHARACTERISTICS—3.3 V OPERATION

All typical specifications are at $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ and $\mathrm{V}_{\mathrm{DD} 1}=\mathrm{V}_{\mathrm{DD} 2}=3.3 \mathrm{~V}$. Minimum and maximum specifications apply over the entire recommended operation range: $3.0 \mathrm{~V} \leq \mathrm{V}_{\mathrm{DD} 1} \leq 3.6 \mathrm{~V}, 3.0 \mathrm{~V} \leq \mathrm{V}_{\mathrm{DD} 2} \leq 3.6 \mathrm{~V}$, and $-40^{\circ} \mathrm{C} \leq \mathrm{T}_{\mathrm{A}} \leq+125^{\circ} \mathrm{C}$, unless otherwise noted. Switching specifications are tested with $\mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}$ and CMOS signal levels, unless otherwise noted.

| Jitter, Low Speed |  |  |  | 2.5 |  |  | 2.5 | $\mu \mathrm{s}$ |  |
| SSAx ${ }^{3}$ Minimum Input Skew ${ }^{4}$ | tssax skEw ${ }^{3}$ | 40 |  |  | 40 |  |  |  |  |

${ }^{1}$ Codirectional channel matching is the absolute value of the difference in propagation delays between any two channels with inputs on the same side of the isolation barrier.
${ }^{2}$ The $\overline{M S S}$ signal is glitch filtered in both speed grades, whereas the other fast signals are not glitch filtered in the $B$ grade. To guarantee that $\overline{M S S}$ reaches the output ahead of another fast signal, set up $\overline{M S S}$ prior to the competing signal by different times depending on speed grade.
${ }^{3}$ SSAx $=$ SSA1 or SSA2.
${ }^{4}$ An internal asynchronous clock, not available to users, samples the low speed signals. If edge sequence in codirectional channels is critical to the end application, the leading pulse must be at least 1 tssaxskew ahead of a later pulse to guarantee the correct order or simultaneous arrival at the output.

${ }^{1}$ See the DC Correctness and Magnetic Field Immunity section for information on the immunity to the external magnetic fields.

Figure 2. Thermal Derating Curve, Dependence of Safety Limiting Values with Case Temperature per DIN V VDE V 0884-10

## ABSOLUTE MAXIMUM RATINGS

$\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, unless otherwise noted
Table 15.

| Parameter | Rating |
| :---: | :---: |
| Storage Temperature ( $\mathrm{Tst}^{\text {) Range }}$ | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Ambient Operating Temperature <br> ( $\mathrm{T}_{\mathrm{A}}$ ) Range | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Supply Voltages (VDD1, , $\mathrm{VDD2}^{\text {) }}$ | -0.5 V to +7.0 V |
| Input Voltages (MCLK, MSS, MO, SO, SSAO, SSA1) | -0.5 V to $\mathrm{V}_{\mathrm{DD}}+0.5 \mathrm{~V}$ |
| Output Voltages (SCLK, MI, SI, SS0 SS1, SS2, SS3) | -0.5 V to $\mathrm{V}_{\mathrm{DD}}+0.5 \mathrm{~V}$ |
| Average Output Current per Pin ${ }^{1}$ | -10 mA to +10 mA |
| Common-Mode Transients ${ }^{2}$ | $-100 \mathrm{kV} / \mu \mathrm{s}$ to $+100 \mathrm{kV} / \mu \mathrm{s}$ |

${ }^{1}$ See Figure 2 for maximum safety rated current values across temperature.
${ }^{2}$ Refers to common-mode transients across the insulation barrier. Commonmode transients exceeding the absolute maximum ratings may cause latch-up or permanent damage.
Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

Table 16. Maximum Continuous Working Voltage ${ }^{1}$

| Parameter | Max | Unit | Constraint |
| :---: | :--- | :--- | :--- |
| AC 60 Hz <br> RMS Voltage | 400 | V rms | 20-year lifetime at 0.1\% <br> failure rate, zero average <br> voltage |
| DC Voltage | 722 | V peak | Limited by the creepage of <br> the package, Pollution <br> Degree 2, Material Group II2,3 |

${ }^{1}$ See the Insulation Lifetime section for details.
${ }^{2}$ Other pollution degree and material group requirements yield a different limit.
${ }^{3}$ Some system level standards allow components to use the printed wiring board (PWB) creepage values. The supported dc voltage may be higher for those standards.

## ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |

Figure 9. Typical Propagation Delay vs. Ambient Temperature for High Speed Channels with Glitch Filter (See the High Speed Channels Section)

## APPLICATIONS INFORMATION <br> INTRODUCTION

The ADuM3154 was created to optimize isolation of the SPI for speed and provide additional low speed channels for control and status monitoring functions. The isolator is based on differential signaling $i$ Coupler technology for enhanced speed and noise immunity.

## High Speed Channels

The ADuM3154 has four high speed channels. The first three channels, CLK, MI/SO, and MO/SI (the slash indicates the connection of the particular input and output channel across the isolator), are optimized for either low propagation delay in the B grade, or high noise immunity in the A grade. The difference between the grades is the addition of a glitch filter to these three channels in the A grade version, which increases the propagation delay. The $B$ grade version, with a maximum propagation delay of 14 ns , supports a maximum clock rate of 17 MHz in standard 4-wire SPI. However, because the glitch filter is not present in the $B$ grade version, ensure that spurious glitches of less than 10 ns are not present.
Glitches of less than 10 ns in the B grade devices can cause the second edge of the glitch to be missed. This pulse condition is then seen as a spurious data transition on the output that is corrected by a refresh or the next valid data edge. It is recommended to use the A grade devices in noisy environments.

The relationship between the SPI signal paths and the pin mnemonics of the ADuM3154 and data directions is detailed in Table 20.

Table 20. Pin Mnemonics Correspondence to SPI Signal Path Names

| SPI Signal <br> Path | Master <br> Side 1 | Data <br> Direction | Slave <br> Side 2 |
| :--- | :--- | :--- | :--- |
| CLK | MCLK | $\rightarrow$ | SCLK |
| $\mathrm{MO} / \mathrm{SI}$ | MO | $\rightarrow$ | SI |
| $\mathrm{MI} / \mathrm{SO}$ | MI | $\leftarrow$ | SO |
| $\overline{\mathrm{SS}}$ | $\overline{\mathrm{MSS}}$ | $\rightarrow$ | SSx |

The datapaths are SPI mode agnostic. The CLK and MOSI SPI datapaths are optimized for propagation delay and channel to channel matching. The MISO SPI datapath is optimized for propagation delay. The device does not synchronize to the clock channel; therefore, there are no constraints on the clock polarity or the timing with respect to the data line. To allow compatibility with nonstandard SPI interfaces, the MI pin is always active, and does not tristate when the slave select is not asserted. This precludes tying several MI lines together without adding a trisate buffer or multiplexor.

The $\overline{\mathrm{SS}}$ (slave select bar) is typically an active low signal. It can have many different functions in SPI and SPI like busses. Many of these functions are edge triggered, so the $\overline{\mathrm{SS}}$ path contains a glitch filter in both the A grade and the B grade. The glitch filter prevents short pulses from propagating to the output or causing other errors in operation. The $\overline{\mathrm{MSS}}$ signal requires a 10 ns setup time in the B grade devices prior to the first active clock edge to allow the added propagation time of the glitch filter.

## Slave Select Multiplexer

The ADuM3154 can control up to four independent slave devices. Figure 10 shows how this can be done using generalpurpose isolators. An isolation channel is required for each slave select; therefore, seven high speed channels are required to transfer bidirectional data to four slaves.

Figure 10. Multiple Slave Control with Standard Isolators

Figure 11 shows how the ADuM3154 can control up to four slaves by routing the MSS input to one of four outputs on the slave side of the isolator, which eliminates three isolation channels compared to the standard solution.

Figure 11. Multiple Slave Control
The multiplexer select lines are low speed channels implemented as part of the dc correctness scheme in the ADuM3154. The dc value of all high and low speed inputs on a given side of the device are sampled simultaneously, packetized, and shifted across an isolation coil. The high speed channels are compared for dc accuracy, and the low speed mux select lines, SSA0 and SSA1, are transferred to the mux control block. The dc correctness data for the high speed channels is handled internally with no visibility off chip.
This data is regulated by a free running internal clock. Because data is sampled at discrete times based on this clock, the propagation delay for mux select lines is between 100 ns and $2.6 \mu \mathrm{~s}$ depending on where the input data edge changes with respect to the internal sample clock. After an address propagation delay time of up to $2.6 \mu$ s, the multiplexer routes the $\overline{\mathrm{MSS}}$ signals to the desired output. The outputs that are not selected are set to high-Z, and the application pulls them to the desired idle state.

Figure 12 illustrates the behavior of the SSA0 and SSA1 channels. This diagram assumes that MSS is low and that SSO, SS1, SS2, and SS3 are pulled up.

Figure 12. Mux Select Timing
The following details the mux select timing shown in Figure 12:

- Point A: The mux select lines must be switched simultaneously to within the tssax skew time. Failure to do this may allow sampling the inputs between the edges and selecting an incorrect mux output. Point A on SS1 is a metastable state on the output mux resulting from wide spacing between SSA0 and SSA1.
- Point B: For mux select lines to be processed predictably, a state of SSA0 and SSA1 must be stable for longer than $4 \mu \mathrm{~s}$ before switching the mux to another output. This guarantees that at least two samples are taken of the inputs before the mux output is changed.
- Point C: This point in Figure 12 shows a clean transfer between SS3 being active and SS0 being active. The mux was designed to eliminate any short duration metastable states between any two selected outputs.

## PRINTED CIRCUIT BOARD (PCB) LAYOUT

The ADuM3154 digital isolator requires no external interface circuitry for the logic interfaces. Power supply bypassing is strongly recommended at both input and output supply pins, $V_{\text {DD1 }}$ and $V_{\text {DD2 }}$ (see Figure 13). The capacitor value must be between $0.01 \mu \mathrm{~F}$ and $0.1 \mu \mathrm{~F}$. The total lead length between both ends of the capacitor and the input power supply pin must not exceed 20 mm .

In applications involving high common-mode transients, it is important to minimize board coupling across the isolation barrier. Furthermore, design the board layout so that any coupling that does occur affects all pins equally on a given component side. Failure to ensure this can cause voltage differentials between pins exceeding the absolute maximum ratings of the device, thereby leading to latch-up or permanent damage.

## PROPAGATION DELAY RELATED PARAMETERS

Propagation delay is a parameter that describes the time it takes a logic signal to propagate through a component. The input to output propagation delay time for a high to low transition may differ from the propagation delay time of a low to high transition.

Figure 14. Propagation Delay Parameters
Pulse width distortion is the maximum difference between these two propagation delay values and an indication of how accurately the timing of the input signal is preserved.
Channel to channel matching refers to the maximum amount the propagation delay differs between channels within a single ADuM3154 component.

## DC CORRECTNESS AND MAGNETIC FIELD IMMUNITY

Positive and negative logic transitions at the isolator input cause narrow ( $\sim 1 \mathrm{~ns}$ ) pulses to be sent via the transformer to the decoder. The decoder is bistable and is, therefore, either set or reset by the pulses indicating input logic transitions. In the absence of logic transitions at the input for more than $\sim 1.2 \mu \mathrm{~s}$, a periodic set of refresh pulses indicative of the correct input state are sent via the low speed channel to ensure dc correctness at the output.
If the low speed decoder receives no pulses for more than about $5 \mu \mathrm{~s}$, the input side is assumed to be unpowered or nonfunctional, in which case, the isolator output is forced to a high- Z state by the watchdog timer circuit.
The limitation on the magnetic field immunity of the device is set by the condition in which induced voltage in the transformer receiving coil is sufficiently large to either falsely set or reset the decoder. The following analysis defines such conditions. The ADuM3154 is examined in a 3 V operating condition because it represents the most susceptible mode of operation for this product.
The pulses at the transformer output have an amplitude greater than 1.5 V . The decoder has a sensing threshold of about 1.0 V ; thereby establishing a 0.5 V margin in which induced voltages can be tolerated. The voltage induced across the receiving coil is given by

$$
\mathrm{V}=(-d \beta / d t) \sum \pi r_{n}^{2} ; n=1,2, \ldots, N
$$

where:
$\beta$ is the magnetic flux density.
$r_{n}$ is the radius of the $n^{\text {th }}$ turn in the receiving coil.
$N$ is the number of turns in the receiving coil.
Given the geometry of the receiving coil in the ADuM3154 and an imposed requirement that the induced voltage be, at most, $50 \%$ of the 0.5 V margin at the decoder, a maximum allowable magnetic field is calculated, as shown in Figure 15.

Figure 15. Maximum Allowable External Magnetic Flux Density

For example, at a magnetic field frequency of 1 MHz , the maximum allowable magnetic field of 0.5 kgauss induces a voltage of 0.25 V at the receiving coil. This is about $50 \%$ of the sensing threshold and does not cause a faulty output transition. If such an event occurs, with the worst-case polarity, during a transmitted pulse, it reduces the received pulse from $>1.0 \mathrm{~V}$ to 0.75 V , which is still well above the 0.5 V sensing threshold of the decoder.
The preceding magnetic flux density values correspond to specific current magnitudes at given distances away from the ADuM3154 transformers. Figure 16 expresses these allowable current magnitudes as a function of frequency for selected distances. The ADuM3154 is insensitive to external fields. Only extremely large, high frequency currents very close to the component are potentially a concern. For the 1 MHz example noted, a user would have to place a 1.2 kA current 5 mm away from the ADuM3154 to affect component operation.

Figure 16. Maximum Allowable Current for Various Current to ADuM3154 Spacings
At combinations of a strong magnetic field and high frequency, any loops formed by the PCB traces may induce sufficiently large error voltages to trigger the thresholds of succeeding circuitry. Take care to avoid PCB structures that form loops.

## POWER CONSUMPTION

The supply current at a given channel of the ADuM3154 isolator is a function of the supply voltage, the data rate of the channel, the output load of the channel, and whether it is a high or low speed channel.
The low speed channels draw a constant quiescent current caused by the internal ping-pong datapath. The operating frequency is low enough that the capacitive losses caused by the recommended capacitive load are negligible compared to the quiescent current. The explicit calculation for the data rate is eliminated for simplicity, and the quiescent current for each side of the isolator due to the low speed channels can be found in Table 3, Table 5, Table 7, and Table 9 for the particular operating voltages.

These quiescent currents add to the high speed current as is shown in the following equations for the total current for each side of the isolator. Dynamic currents are taken from Table 3 and Table 5 for the respective voltages.
For Side 1 , the supply current is given by

$$
\begin{aligned}
& I_{D D I}=I_{D D I(D)} \times\left(f_{M C L K}+f_{M O}+f_{\overline{M S S}}\right)+ \\
& f_{M I} \times\left(I_{D D O(D)}+\left(\left(0.5 \times 10^{-3}\right) \times C_{L(M I)} \times V_{D D I}\right)\right)+I_{D D I(Q)}
\end{aligned}
$$

For Side 2, the supply current is given by

$$
\begin{aligned}
& I_{D D 2}=I_{D D I(D)} \times f_{S O}+ \\
& f_{S C L K} \times\left(I_{D D O(D)}+\left(\left(0.5 \times 10^{-3}\right) \times C_{L(S C L K)} \times V_{D D 2}\right)\right)+ \\
& f_{S I} \times\left(I_{D D O(D)}+\left(\left(0.5 \times 10^{-3}\right) \times C_{L(S I)} \times V_{D D 2}\right)\right)+ \\
& f_{S S x} \times\left(I_{D D O(D)}+\left(\left(0.5 \times 10^{-3}\right) \times C_{L(S S x)} \times V_{D D 2}\right)\right)+I_{D D 2(Q)}
\end{aligned}
$$

where:
$I_{D D I(D)}, I_{D D O(D)}$ are the input and output dynamic supply currents per channel (mA/Mbps).
$f_{\mathrm{x}}$ is the logic signal data rate for the specified channel (Mbps). $C_{L(x)}$ is the load capacitance of the specified output ( pF ). $V_{D D x}$ is the supply voltage of the side being evaluated (V). $I_{D D 1(Q)}, I_{D D 2(Q)}$ are the specified Side 1 and Side 2 quiescent supply currents (mA).
Figure 4 and Figure 7 show the supply current per channel as a function of data rate for an input and unloaded output. Figure 5 and Figure 8 show the total $I_{D D 1}$ and $\mathrm{I}_{\mathrm{DD} 2}$ supply currents as a function of data rate for ADuM 3154 channel configurations with all high speed channels running at the same speed and the low speed channels at idle.

## INSULATION LIFETIME

All insulation structures eventually break down when subjected to voltage stress over a sufficiently long period. The rate of insulation degradation is dependent on the characteristics of the voltage waveform applied across the insulation, as well as the materials and material interfaces.

Two types of insulation degradation are of primary interest: breakdown along surfaces exposed to the air and insulation wear out. Surface breakdown is the phenomenon of surface tracking and the primary determinant of surface creepage requirements in system level standards. Insulation wear out is the phenomenon where charge injection or displacement currents inside the insulation material cause long-term insulation degradation.

## Surface Tracking

Surface tracking is addressed in electrical safety standards by setting a minimum surface creepage based on the working voltage, the environmental conditions, and the properties of the insulation material. Safety agencies perform characterization testing on the surface insulation of components that allow the components to be categorized in different material groups. Lower material group ratings are more resistant to surface tracking and, therefore, can provide adequate lifetime with smaller creepage. The minimum creepage for a given working voltage and material group is in each system level standard and is based on the total rms voltage across the isolation, pollution degree, and material group. The material group and creepage for the ADuM3154 isolator are detailed in Table 12.

## Insulation Wear Out

The lifetime of insulation caused by wear out is determined by its thickness, the material properties, and the voltage stress applied. It is important to verify that the product lifetime is adequate at the application working voltage. The working voltage supported by an isolator for wear out may not be the same as the working voltage supported for tracking. It is the working voltage applicable to tracking that is specified in most standards.

Testing and modeling have shown that the primary driver of long-term degradation is displacement current in the polyimide insulation causing incremental damage. The stress on the insulation can be broken down into two broad categories, such as dc stress, which causes very little wear out because there is no displacement current, and an ac component time varying voltage stress, which causes wear out.

The ratings in certification documents are usually based on 60 Hz sinusoidal stress, because this reflects isolation from line voltage. However, many practical applications have combinations of 60 Hz ac and dc across the barrier, as shown in Equation 1. Because only the ac portion of the stress causes wear out, the equation can be rearranged to solve for the ac rms voltage, as shown in Equation 2. For insulation wear out with the polyimide materials used in this product, the ac rms voltage determines the product lifetime.

$$
\begin{equation*}
V_{R M S}=\sqrt{V_{A C R M S}{ }^{2}+V_{D C}{ }^{2}} \tag{1}
\end{equation*}
$$

or

$$
\begin{equation*}
V_{A C R M S}=\sqrt{V_{R M S}^{2}-V_{D C}^{2}} \tag{2}
\end{equation*}
$$

where:
$V_{\text {RMS }}$ is the total rms working voltage.
$V_{A C R M S}$ is the time varying portion of the working voltage.
$V_{D C}$ is the dc offset of the working voltage.

## Calculation and Use of Parameters Example

The following is an example that frequently arises in power conversion applications. Assume that the line voltage on one side of the isolation is $240 \mathrm{~V}_{\mathrm{AC}}$ RMS, and a $400 \mathrm{~V}_{\mathrm{dC}}$ bus voltage is present on the other side of the isolation barrier. The isolator material is polyimide. To establish the critical voltages in determining the creepage clearance and lifetime of a device, see Figure 17 and the following equations.

Figure 17. Critical Voltage Example
The working voltage across the barrier from Equation 1 is

$$
\begin{aligned}
& V_{R M S}=\sqrt{V_{A C R M S}^{2}+V_{D C}^{2}} \\
& V_{R M S}=\sqrt{240^{2}+400^{2}} \\
& V_{R M S}=466 \mathrm{~V}
\end{aligned}
$$

This is the working voltage used together with the material group and pollution degree when looking up the creepage required by a system standard.

To determine if the lifetime is adequate, obtain the time varying portion of the working voltage. The ac rms voltage can be obtained from Equation 2.

$$
\begin{aligned}
& V_{A C R M S}=\sqrt{V_{R M S}^{2}-V_{D C}^{2}} \\
& V_{A C ~ R M S}=\sqrt{466^{2}-400^{2}} \\
& V_{A C R M S}=240 \mathrm{~V}_{\mathrm{RMS}}
\end{aligned}
$$

In this case, the $V_{\text {acrms }}$ is simply the line voltage of $240 \mathrm{~V}_{\text {rms }}$. This calculation is more relevant when the waveform is not sinusoidal. The value is compared to the limits for the working voltage listed in Table 16 for the expected lifetime, under a 60 Hz sine wave, and it is well within the limit for a 50 -year service life.

Note that the dc working voltage limit in Table 16 is set by the creepage of the package as specified in IEC 60664-1. This value may differ for specific system level standards.

## OUTLINE DIMENSIONS

COMPLIANT TO JEDEC STANDARDS MO-150-AE
