## Data Sheet

## FEATURES

Maximum supply current: $90 \boldsymbol{\mu A}$
Minimum CMRR: 100 dB
Drives heavy capacitive loads: ~700 pF
Rail-to-rail output
Input voltage range goes below ground
Gain set with 2 external resistors
Can achieve low gain drift at any gain
Very wide power supply range
Single supply: 2.7 V to 36 V
Dual supply: $\pm 2.7 \mathrm{~V}$ to $\pm 18 \mathrm{~V}$
Bandwidth (G = 100): $\mathbf{2 . 5} \mathbf{~ k H z}$
Input voltage noise: $\mathbf{5 5} \mathbf{n V} / \sqrt{ } \mathbf{H z}$
High dc precision
Maximum offset voltage: $\mathbf{1 2 5 ~ \mu V}$
Maximum offset drift: $1 \mu \mathrm{~V} /{ }^{\circ} \mathrm{C}$
Maximum differential input voltage: $\pm 1 \mathrm{~V}$
8-lead MSOP package

## APPLICATIONS

Bridge amplifiers
Pressure measurement
Medical instrumentation
Portable data acquisition
Multichannel systems

## GENERAL DESCRIPTION

The AD8420 is a low cost, micropower, wide supply range, instrumentation amplifier with a rail-to-rail output and a novel architecture that allows for extremely flexible design. It is optimized to amplify small differential voltages in the presence of large common-mode signals.
The AD8420 is based on an indirect current feedback architecture that gives it an excellent input common-mode range. Unlike conventional instrumentation amplifiers, the AD8420 can easily amplify signals at or even slightly below ground without requiring dual supplies. The AD8420 has rail-to-rail output, and the output voltage swing is completely independent of the input commonmode voltage.

## PIN CONFIGURATION

Table 1. Instrumentation Amplifiers by Category ${ }^{1}$

| General Purpose | Zero Drift | Military Grade | Low Power | Digital Gain |
| :---: | :---: | :---: | :---: | :---: |
| AD8221, AD8222 | AD8231 | AD620 | AD8420 | AD8250 |

|  | AD8557 |  | AD8223 |  |

${ }^{1}$ See www.analog.com for the latest instrumentation amplifiers.

Single-supply operation, micropower current consumption, and rail-to-rail output swing make the AD8420 ideal for batterypowered applications. Its rail-to-rail output stage maximizes dynamic range when operating from low supply voltages. Dualsupply operation ( $\pm 15 \mathrm{~V}$ ) and low power consumption make the AD8420 ideal for a wide variety of applications in medical or industrial instrumentation.

The AD8420 is available in an 8 -lead MSOP package. Performance is specified over the full temperature range of $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$, and the device is operational from $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$.

${ }^{1}$ See the Typical Performance Characteristics section for the offset voltage vs. supply.
${ }^{2}$ The input stage uses PNP transistors; therefore, input bias current always flows out of the device.
${ }^{3}$ For G > 1, errors from External Resistor R1 and External Resistor R2 should be considered in addition to these specifications, including error from FB pin bias current.
${ }^{4}$ Minimum positive supply voltage indicated for $\mathrm{V}_{+ \text {IN }}, \mathrm{V}_{- \text {IN }}$, and $\mathrm{V}_{\text {REF }}=0 \mathrm{~V}$. With $\mathrm{V}_{+ \text {IN }}, \mathrm{V}_{\text {-IN }}$, and $\mathrm{V}_{\text {REF }}=-\mathrm{V}_{S}$, minimum supply is $\pm 1.35 \mathrm{~V}$.
${ }^{5}$ See the Typical Performance Characteristics section for operation between $85^{\circ} \mathrm{C}$ and $125^{\circ} \mathrm{C}$.

## ABSOLUTE MAXIMUM RATINGS

Table 4.

| Parameter | Rating |
| :--- | :--- |
| Supply Voltage | $\pm 18 \mathrm{~V}$ |
| Output Short-Circuit Current | Indefinite |
| Maximum Voltage at -IN or +IN | $-\mathrm{V}_{\mathrm{s}}+40 \mathrm{~V}$ |
| Minimum Voltage at -IN or +IN | $-\mathrm{V}_{\mathrm{s}}-0.5 \mathrm{~V}$ |
| Maximum Voltage at REF or FB | $+\mathrm{V}_{\mathrm{s}}+0.5 \mathrm{~V}$ |
| Minimum Voltage at REF or FB | $-\mathrm{V}_{\mathrm{s}}-0.5 \mathrm{~V}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| ESD |  |
| $\quad$ Human Body Model | 4 kV |
| Charge Device Model | 1.25 kV |
| Machine Model | 0.2 kV |

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## THERMAL RESISTANCE

$\theta_{J A}$ is specified for a device in free air.
Table 5.

| Package | $\boldsymbol{\theta}_{\mathrm{JA}}$ | Unit |
| :--- | :--- | :--- |
| 8-Lead MSOP, 4-Layer JEDEC Board | 135 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

## ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |
| :--- | :--- |

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Table 6. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :--- | :--- | :--- |
| 1 | NC | This pin is not connected internally. For best CMRR vs. frequency and leakage performance, connect this pin to |
| negative supply. |  |  |
| 2 | + IN | Positive Input. |
| 3 | $-I N$ | Negative Input. |
| 4 | $-V_{S}$ | Negative Supply. |
| 5 | $+V_{S}$ | Positive Supply. |
| 6 | REF | Reference Input. |
| 7 | FB | Feedback Input. |
| 8 | Vout | Output. |

## TYPICAL PERFORMANCE CHARACTERISTICS

$\mathrm{T}=25^{\circ} \mathrm{C},+\mathrm{V}_{\mathrm{S}}=5 \mathrm{~V}, \mathrm{R}_{\mathrm{L}}=20 \mathrm{k} \Omega$, unless otherwise noted.

## THEORY OF OPERATION

Figure 58. Simplified Schematic

## ARCHITECTURE

The AD8420 is based on an indirect current feedback topology consisting of three amplifiers: two matched transconductance amplifiers that convert voltage to current and one integrator amplifier that converts current to voltage.
For the AD8420, assume that all initial voltages and currents are zero until a positive differential voltage is applied between the inputs, + IN and -IN. Transconductance Amplifier $\mathrm{g}_{\mathrm{m} 1}$ converts this input voltage into a current, I1. Because the voltage across $\mathrm{g}_{\mathrm{m} 2}$ is initially zero, I2 is zero and I3 equals I1.
I3 is integrated to the output, making the output voltage, Vout, increase. This voltage continues to increase until the same differential input voltage across the inputs of $g_{m 1}$ is replicated across the inputs of $\mathrm{g}_{\mathrm{m} 2}$, generating a current (I2) equal to I1. This reduces the Difference Current I3 to zero so that the output remains at a stable voltage. The gain in the configuration shown in Figure 58 is set by R2 and R1.

In traditional instrumentation amplifiers, the input commonmode voltage can limit the available output swing, typically depicted in a hexagon plot. Because the AD8420 converts the input differential signals to current, this limit does not apply. This is particularly important when amplifying a signal with a commonmode voltage near one of the supply rails.
To improve robustness and ease of use, the AD8420 includes differential voltage protection to limit the current into its inputs to a safe level. This protection scheme allows wide differential input voltages without damaging the device.

## SETTING THE GAIN

The transfer function of the AD8420 is

$$
V_{\text {OUT }}=G\left(V_{+I N}-V_{-I N}\right)+V_{\text {REF }}
$$

where $G=1+\frac{R 2}{R 1}$.

Table 7. Suggested Resistors for Various Gains, 1\% Resistors

| R1 $(\mathbf{k} \boldsymbol{\Omega})$ | R2 $(\mathbf{k} \boldsymbol{\Omega})$ | Gain |
| :--- | :--- | :--- |
| None | Short | 1.00 |
| 49.9 | 49.9 | 2.00 |
| 20 | 80.6 | 5.03 |
| 10 | 90.9 | 10.09 |
| 5 | 95.3 | 20.06 |
| 2 | 97.6 | 49.8 |
| 1 | 100 | 101 |
| 1 | 200 | 201 |
| 1 | 499 | 500 |
| 1 | 1000 | 1001 |

While the ratio of R 2 to R 1 sets the gain, the designer determines the absolute value of the resistors. Larger values reduce power consumption and output loading; smaller values limit the FB input bias current and offset current error. For best output swing and distortion performance, keep (R1 + R2) \| $\mathrm{R}_{\mathrm{L}} \geq 20 \mathrm{k} \Omega$.
A method that allows large value feedback resistors while limiting FB bias current error is to place a resistor of value R1 || R2 in series with the REF terminal, as shown in Figure 59. At higher gains, this resistor can simply be the same value as R1.

Figure 59. Cancelling Out Error from FB Input Bias Current

## GAIN ACCURACY

Unlike most instrumentation amplifiers, the relative match of the two gain setting resistors determines the gain accuracy of the AD8420 rather than a single resistor. For example, if two resistors have exactly the same absolute error, there is no error in gain. Conversely, two $1 \%$ resistors can cause approximately $2 \%$ maximum gain error at high gains. Temperature coefficient mismatch of the gain setting resistors increases the gain drift of the instrumentation amplifier circuit, according to the gain equation. Because these external resistors do not have to match any on-chip resistors, resistors with good TC tracking can achieve excellent gain drift. Even with standard thin film resistors, the AD8420 can still achieve better gain drift than most instrumentation amplifiers.
When the differential voltage at the inputs approaches the differential input limit, the diodes start to conduct, limiting the voltage seen by the inputs of amplifier $\mathrm{g}_{\mathrm{m} 1}$. This can look like increased gain error at large differential inputs. Performance of the AD8420 is specified for $\pm 1 \mathrm{~V}$ differential from $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$. However, at higher temperatures, the reduced forward voltage of the diodes limits the differential input to a smaller voltage. Figure 60 tracks $1 \%$ error across the operating temperature range to show the effect of temperature on the input limit.

Figure 60. Differential Input Limit vs. Temperature

## INPUT VOLTAGE RANGE

The allowed input range of the AD8420 is much simpler than traditional architectures. For the transfer function of the AD8420 to be valid, the input voltage should follow two rules:

- Keep the differential input voltage within $\pm 1 \mathrm{~V}$.
- Keep the voltage on the +IN, -IN, REF, and FB pins in the specified input voltage range.
Because the output swing is completely independent of the input common-mode voltage, there are no hexagonal figures or complicated formulas to follow, and no limitation for the output swing the amplifier has for input signals with changing common mode.

## INPUT PROTECTION

The current into the AD8420 inputs is limited internally. This ensures that the diodes that limit the differential voltage seen by the internal amplifier do not draw excessive current when they turn on. The device can handle large differential input voltages, regardless of the amount of gain applied, without damage. As a result, the AD8420 inputs are protected from voltages beyond the positive rail. If voltages beyond the negative rail are expected, external protection must be used.
Keep all of the AD8420 terminals within the voltage range specified in the Absolute Maximum Ratings section. All terminals of the AD8420 are protected against ESD.

## Input Voltages Beyond the Rails

For applications that require protection beyond the negative rail, one option is to use an external resistor in series with each input to limit current during overload conditions. In this case, size the resistors to limit the current into the AD8420 to 6 mA .

$$
R_{P R O T E C T} \geq\left(\text { Negative Supply }-V_{I N}\right) / 6 \mathrm{~mA}
$$

Although the AD8420 inputs must still be kept within the $-\mathrm{V}_{\mathrm{s}}+$ 40 V limitation, the $\mathrm{I} \times \mathrm{R}$ drop across the protection resistor increases the protection on the positive side to approximately

$$
(40 \mathrm{~V}+\text { Negative Supply })+300 \mu \mathrm{~A} \times \text { RР尺ОТЕСт }
$$

An alternate protection method is to place diodes at the AD8420 inputs to limit voltage and resistors in series with the inputs to limit the current into these diodes. To keep input bias current at a minimum for normal operation, use low leakage diode clamps, such as the BAV199. The AD8420 also combines well with TVS diodes, such as the PTVSxS1UR.

Figure 61. Protection for Voltages Beyond the Rails

## Large Differential Input Voltage

The AD8420 is able to handle large differential input voltage without damage to the device. Refer to Figure 9, Figure 10, Figure 11, and Figure 12 for overvoltage performance. The AD8420 differential voltage is internally limited with diodes to $\pm 1 \mathrm{~V}$. If this limit is exceeded, the diodes start to conduct and draw current, as shown in Figure 22. This current is limited internally to a value that is safe for the AD8420, but if the input current cannot be tolerated in the system, place resistors in series with each input with the following value:

$$
R_{\text {PROTECT }} \geq \frac{1}{2}\left(\frac{\left|V_{D I F F}\right|-1 \mathrm{~V}}{I_{M A X}}\right)
$$

## LAYOUT

## Common-Mode Rejection Ratio over Frequency

Poor layout can cause some of the common-mode signal to be converted to a differential signal before reaching the in-amp. This conversion can occur when the path to the positive input pin has a different frequency response than the path to the negative input pin. For best CMRR vs. frequency performance, the input source impedance and capacitance of each path should be closely matched. This includes connecting Pin 1 to $-\mathrm{V}_{\mathrm{s}}$, which matches the parasitic capacitance and the leakage between the inputs and adjacent pins. Place additional source resistance in the input path (for example, for input protection) close to the in-amp inputs to minimize their interaction with the parasitic capacitance from the printed circuit board (PCB) traces.

## Power Supplies

Use a stable dc voltage to power the instrumentation amplifier. Noise on the supply pins can adversely affect performance. For more information, see the PSRR performance curves in Figure 24 and Figure 25.
Place a $0.1 \mu \mathrm{~F}$ capacitor as close as possible to each supply pin. As shown in Figure 62, a $10 \mu \mathrm{~F}$ tantalum capacitor can be used farther away from the device. This capacitor, which is intended to be effective at low frequencies, can usually be shared by other precision integrated circuits. Keep the traces between these integrated circuits short to minimize interaction of the trace parasitic inductance with the shared capacitor.

Figure 62. Supply Decoupling, REF, and Output Referred to Local Ground

## Reference

The output voltage of the AD8420 is developed with respect to the potential on the reference terminal. Take care to tie REF to the appropriate local ground. The differential voltage at the inputs is reproduced between the REF and FB pins; therefore, it is important to set $V_{\text {Ref }}$ so that the voltage at FB does not exceed the input range.

## DRIVING THE REFERENCE PIN

Traditional instrumentation amplifier architectures require the reference pin to be driven with a low impedance source. In these architectures, impedance at the reference pin degrades both CMRR and gain accuracy. With the AD8420 architecture, resistance at the reference pin has no effect on CMRR.

Figure 63. Calculating Gain with Reference Resistance
Resistance at the reference pin does affect the gain of the AD8420, but if this resistance is constant, the gain setting resistors can be adjusted to compensate. For example, the AD8420 can be driven with a voltage divider to level shift the output as shown in Figure 64.

Figure 64. Using Resistor Divider to Set Reference Voltage

Figure 65. Creating an IBAAS Path

## INPUT BIAS CURRENT RETURN PATH

The input bias current of the AD8420 must have a return path to ground. When the source, such as a thermocouple, cannot provide a return current path, create one, as shown in Figure 65.

## RADIO FREQUENCY INTERFERENCE (RFI)

All instrumentation amplifiers can rectify high frequency out-ofband signals. Once rectified, these signals appear as dc offset errors at the output. High frequency signals can be filtered with a low-pass RC network placed at the input of the instrumentation amplifier, as shown in Figure 66. The filter limits the input signal bandwidth according to the following relationship:

$$
\begin{aligned}
& \text { FilterFrequency }_{\text {DIFF }}=\frac{1}{2 \pi R\left(2 C_{D}+C_{C}\right)} \\
& \text { FilterFrequency }_{C M}=\frac{1}{2 \pi R C_{C}}
\end{aligned}
$$

where $C_{D} \geq 10 C_{C}$.

Figure 66. Suggested RFI Suppression Filter
$C_{D}$ affects the differential signal and $C_{C}$ affects the common-mode signal. Values of R and $\mathrm{C}_{\mathrm{C}}$ are chosen to minimize out of band RFI at the expense of reduced signal bandwidth. Mismatch between the $\mathrm{R} \times \mathrm{C}_{\mathrm{C}}$ at the positive input and the $\mathrm{R} \times \mathrm{C}_{\mathrm{C}}$ at the negative input degrades the CMRR of the AD8420. By using a value of $C_{D}$ that is at least one magnitude larger than $C_{C}$, the effect of the mismatch is reduced and performance is improved.

## OUTPUT BUFFERING

The AD8420 is designed to drive loads of $20 \mathrm{k} \Omega$ or greater but can deliver up to 10 mA to heavier loads at lower output voltage swings (see Figure 42). If more output current is required, buffer the AD8420 output with a precision op amp. Figure 67 shows the recommended configuration using the ADA4692-2 with a single supply. This low power op amp can swing its output from 1 V to 4 V on a single 5 V supply while sourcing or sinking more than 30 mA of current. When using this configuration, the load seen by the AD8420 is approximately R1 + R2.

Figure 67. Output Buffering

Because the ADA4692-2 is a dual op amp, another op amp is now free for use as an active filter stage or to buffer another AD8420 output on the same PCB. Figure 68 shows another suggestion for how to use this second op amp. In this circuit, the voltage from the wiper of a potentiometer is buffered by the ADA4692-2, allowing a variable level shift of the output. Resistors above and below the potentiometer reduce the total range of the level shift but increase the precision. If the potentiometer were connected directly to the REF pin of the AD8420, gain error would be introduced from the variable resistance. The potentiometer can be tuned in hardware or software, depending on the type of potentiometer chosen. For a list of digital potentiometers made by Analog Devices, Inc., visit www.analog.com/digitalpotentiometers.

Figure 68. Variable Level Shift

## APPLICATIONS INFORMATION <br> AD8420 IN ELECTROCARDIOGRAPHY (ECG)

A high-pass filter is commonly used in ECG signal conditioning circuitry to remove electrode offset and motion artifacts. To avoid degrading the input impedance and CMRR of the system, this filtering is typically implemented after the instrumentation amplifier, which limits the gain that can be applied with the instrumentation amplifier.
With a 3-op-amp instrumentation amplifier, gain is applied in the first stage. Because of this, the electrode offset is gained and then must be removed afterward with a high-pass filter. In the AD8420 architecture, the offset can be accounted for in the input stage
by unbalancing the transconductance amplifier at the REF and FB pins. In the steady state, the offset at the input is not gained to the output, and higher frequency signals can be gained and passed through. Using the AD8420 in this way, the offset tolerance is nearly the differential input range of the device $( \pm 1 \mathrm{~V})$.
Figure 69 shows an ECG front end that applies a gain of 100 to the signal while rejecting dc and high frequencies. This circuit combines the AD8420 with the AD8657, which is a low power, low cost, dual, precision CMOS op amp.

Figure 69. AD8420 in an ECG Front End

## CLASSIC BRIDGE CIRCUIT

Figure 70 shows the AD8420 configured to amplify the signal from a classic resistive bridge. This circuit works in dual-supply mode or single-supply mode. Typically, the same voltage that powers the instrumentation amplifier excites the bridge. Connecting the bottom of the bridge to the negative supply of the instrumentation amplifier sets up an input common-mode voltage that is located midway between the supply voltages. The voltage on the REF pin can be varied to suit the application. For example, the REF pin is tied to the $V_{\text {REF }}$ pin of an analog-to-digital converter (ADC) whose input range is ( $\mathrm{V}_{\text {ref }} \pm \mathrm{V}_{\text {IN }}$ ). With an available output swing on the AD8420 of $\left(-\mathrm{V}_{\mathrm{s}}+100 \mathrm{mV}\right)$ to $\left(+\mathrm{V}_{\mathrm{s}}-150 \mathrm{mV}\right)$, the maximum programmable gain is simply this output range divided by the input range.

Figure 70. Classic Bridge Circuit

## 4 mA TO 20 mA SINGLE-SUPPLY RECEIVER

The $90 \mu \mathrm{~A}$ maximum supply current, input range that goes below ground, and low drift characteristics make the AD8420 a very good candidate for use in a 4 mA to 20 mA loop. Figure 71 shows how a signal from a 4 mA to 20 mA transducer can be interfaced to the AD8420. The signal from a 4 mA to 20 mA transducer is single-ended, which initially suggests the need for a simple shunt resistor to ground to convert the current to a voltage. However, any line resistance in the return path (to the transducer) adds a current-dependent offset error; therefore, the current must be sensed differentially.
In this example, a $5 \Omega$ shunt resistor generates a differential voltage at the inputs of the AD8420 between 20 mV (for 4 mA in ) and 100 mV (for 20 mA in ) with a very low common-mode value. With the gain resistors shown, the AD8420 amplifies the 100 mV input voltage by a factor of 40 to 4.0 V .
