

M6800 CLOCK GENERATOR

Intended to supply the non-overlapping $\phi 1$ and $\phi 2$ clock signals required by the microprocessor, this clock generator is compatible with 1.0, 1.5, and 2.0 MHz versions of the MC6800. Both the oscillator and high capacitance driver elements are included along with numerous other logic accessory functions for easy system expansion.

Schottky technology is employed for high speed and PNP-buffered inputs are employed for NMOS compatibility. A single +5 V power supply, and a crystal or RC network for frequency determination are required.

DESCRIPTION OF PIN FUNCTIONS

- $4 \times f_o$ — A free running oscillator at four times the MPU clock rate useful for a system sync signal.
- $2 \times f_o$ — A free running oscillator at two times the MPU clock rate.
- DMA/REF REQ — An asynchronous input used to freeze the MPU clocks in the $\phi 1$ high, $\phi 2$ low state for dynamic memory refresh or cycle steal DMA (Direct Memory Access).
- REF GRANT — A synchronous output used to synchronize the refresh or DMA operation to the MPU.
- MEMORY READY — An asynchronous input used to freeze the MPU clocks in the $\phi 1$ low, $\phi 2$ high state for slow memory interface.
- MPU $\phi 1$ — Capable of driving the $\phi 1$ and $\phi 2$ inputs on two MC6800s.
- MPU $\phi 2$
- BUS $\phi 2$ — An output nominally in phase with MPU $\phi 2$ having MCBT26A type drive capability.
- MEMORY CLOCK — An output nominally in phase with MPU $\phi 2$ which free runs during a refresh request cycle.
- POWER-ON RESET — A Schmitt trigger input which controls Reset. A capacitor to ground is required to set the desired time constant. Internal 50 k resistor to V_{CC} . See General Design Suggestions for Manual Reset Operation.
- RESET — An output to the MPU and I/O devices.
- X1, X2 — Provision to attach a series resonant crystal or RC network.
- EXT IN — Allows driving by an external TTL signal to synchronous the MPU to an external system.

APPLICATIONS INFORMATION

FIGURE 9 – TYPICAL RC FREQUENCY versus VOLTAGE

FIGURE 10 – TYPICAL RC FREQUENCY versus TEMPERATURE

FIGURE 11 – TYPICAL FREQUENCY versus RESISTANCE FOR C VARIABLE

GENERAL

The MC6875 Clock Generator/Driver should be located on the same board and within two inches of the MC6800 MPU. Series damping resistors of 10-30 ohms may be utilized between the MC6875 and the MC6800 on the $\phi 1$ and $\phi 2$ clocks to suppress overshoot and reflections.

The V_{CC} pin (pin 16) of the MC6875 should be bypassed to the ground pin (pin 8) at the package with a 0.1 μF capacitor. Because of the high peak currents associated with driving highly capacitive loads, an adequately large ground strip to pin 8 should be used on the MC6875. Grounds should be carefully routed to minimize coupling of noise to the sensitive oscillator inputs. Unnecessary grounds or ground planes should be avoided near pin 2 or the frequency determining components. These components should be located as near as possible to the respective pins of the MC6875. Stray capacitance near pin 2 or the crystal, can affect the frequency. The can of the crystal should not be grounded. The ground side of the crystal or the C of the R-C oscillator should be connected as directly as possible to pin 8.

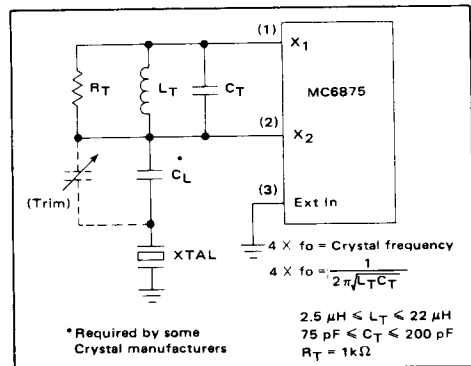

Unused inputs should be connected to V_{CC} or ground. Memory Ready, DMA/Refresh Request and Power-On Reset should be connected to V_{CC} when not used. The External Input should be connected to ground when not used.

OSCILLATOR

A tank circuit tuned to the desired crystal frequency connected between terminals X_1 and X_2 as shown in Figure 12, is recommended to prevent the oscillator from starting at other than the desired frequency. The 1k Ω resistor reduces the Q sufficiently to maintain stable crystal control. Crystal manufacturers may recommend a capacitance (C_L) to be used in series with the crystal for optimum performance at series resonance.

See Figures 9 and 10 for typical oscillator temperature and V_{CC} supply dependence for R-C operation.

FIGURE 13

To precisely time a crystal to desired frequency, a variable trimmer capacitor in the range of 7 to 40 pF would typically be used. Note it is not a recommended practice to tune the crystal with a parallel load capacitance.

The table above shows typical values for C_T and L_T, typical crystal characteristics, and manufacturers' part numbers for 4.0 and 8.0 megahertz operation.

The MC6875 will function as an R-C oscillator when connected as shown in Figure 13. The desired output frequency (Mφ1) is approximately:

$$4 \times f_0 \approx \frac{320}{C(R + .27) + 23}$$

C in picofarads
R in Kohms

(See Figure 11)

It would be desirable to select a capacitor greater than 15 pF to minimize the effects of stray capacitance. It is also desirable to keep the resistor in the 1 to 5 k Ω range. There is a nominal 270 Ω resistor internally at X₁ which is in series with the external R. By keeping the external R as large as possible, the effects due to process variations of the internal resistor on the frequency will be reduced. There will, however, still be some variation in frequency in a production lot both from the resistance variations, external and internal, and process variations of the input switching thresholds. Therefore, in a production system, it is recommended a potentiometer be placed in series with a fixed R between X₁ and X₂.

POWER-ON RESET

As the power to the MC6875 comes up, the Reset Output will be in a high impedance state and will not give

a solid V_{OL} output level until V_{CC} has reached 3.5 to 4.0 V. During this time transients may appear on the clock outputs as the oscillator begins to start. This happens at approximately V_{CC} = 3 V. At some V_{CC} level above that, where Reset Output goes low, all the clock outputs will begin functioning normally. This phenomenon of the start-up sequence should not cause any problems except possibly in systems with battery back-up memory. The transients on the clock lines during the time the Reset Output is high impedance could initiate the system in some unknown mode and possibly write into the backup memory system. Therefore in battery backup systems, more elaborate reset circuitry will be required.

Please note that the Power-On Reset input pin of the MC6875 is not suitable for use with a manual MPU reset switch if the DMA/Ref Req or Memory Ready inputs are going to be used. The power on reset circuitry is used to initialize the internal control logic and whenever the input is switched low, the MC6875 is irresponsive to the DMA/Ref Req or Memory Ready inputs. This may result in the loss of dynamic memory and/or possibly a byte of slow static memory. The circuit of Figure 14 is recommended for applications which do not utilize the DMA/Ref Req or Memory Ready inputs. The circuit of Figure 15 is recommended for those applications that do.
