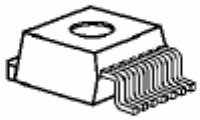
5-V Low-Drop Voltage Regulator

ILE4267

ILE 4267 is a 5-V low-drop voltage regulator in a TO220-7 package. It supplies an output current of > 400 mA. The IC is shortcircuit-proof and incorporates temperature protection that disables the IC at overtemperature.

ILE 4267 G



ILE 4267 S

ILE 4267 G – packege P-TO220-7-180
ILE 4267 S – packege P-TO220-7-230
T_A = -40° ÷ 125° C for all packages.

Features

- Output voltage tolerance ≤ ± 2 %
- 400 mA output current capability
- Low-drop voltage
- Very low standby current consumption
- Input voltage up to 40 V
- Overvoltage protection up to 60 V (≤ 400 ms)
- Reset function down to 1 V output voltage
- ESD protection up to 2000 V
- Adjustable reset time
- On/off logic
- Overtemperature protection
- Reverse polarity protection
- Short-circuit proof
- Wide temperature range
- Suitable for use in automotive electronics

Application

The IC regulates an input voltage *V,* in the range 5.5 V < Vi < 40 V to V_{Qrated} = 5.0 V. A reset signal is generated for an output voltage V_Q of < 4.5 V. The reset delay can be set with an external capacitor. The device has two logic inputs. It is turned-ON by a voltage of > 4 V on E2 by the ignition for example. It remains active as a function of the voltage on E6, even if the voltage on E2 goes Low. This makes it possible to implement a self-holding circuit without external components. When the device is turned-OFF, the output voltage drops to 0 V and current consumption tends towards 0 μA.

Design Notes for External Components

The input capacitor Ci is necessary for compensation line influences. The resonant circuit consisting of lead inductance and input capacitance can be damped by a resistor of approx. 1 Ω in series with Ci. The output capacitor is necessary for the stability of the regulating circuit. Stability is guaranteed at values of ≥ 22 μF and an ESR of ≤ 3 Ω within the operating temperature range.

Circuit Description

The control amplifier compares a reference voltage, which is kept highly accurate by resistance adjustment, to a voltage that is proportional to the output voltage and drives the base of the series transistor via a buffer. Saturation control as a function of the load current prevents any over-saturating of the power element.
A comparator in the reset-generator block compares a reference that is independent of the input voltage to the scaled-down output voltage. If this reaches a value of 4.5 V, the reset-delay capacitor is discharged and then the reset output is set Low. As the output voltage increases again, the reset-delay capacitor is charged with constant current from V_Q = 4.5 V onwards. When the capacitor voltage reaches the upper switching threshold, reset goes High again. The reset delay can be set within wide range by selection of the external capacitor. With the integrated tum-ON/tum-OFF logic it is simple to implement delayed tum-OFF without external components.

Truth Table for Turn-ON/Turn-OFF Logic

E2, Inhibit	Hold	V_Q	Remarks
L	X	OFF	Initial state. Inhibit internally pulled up
H	X	ON	Regulator switched on via Inhibit, by ignition for example
H	L	ON	Hold clamped active to ground by controller while Inhibit is still high
X	L	ON	Previous state remains, even ignition is shut off: self-holding state
L	L	ON	Ignition shut off while regulator is in self-holding state
L	H	OFF	Regulator shut down by releasing of Hold while Inhibit remains Low, final state. No active clamping required by external self-holding circuit (μC) to keep regulator shut off.

Inhibit: E2 Enable function, active High
Hold: E6 Hold and release function, active Low

Pin Definitions and Functions

Pin	Symbol	Function
1	I	**Input**; block to ground directly at the IC by a ceramic capacitor
2	E2	**Inhibit**; device is turned-ON by High signal on this pin; internal pulldown resistor of 100 kΩ
3	R	**Reset Output**; open-collector output internally connected to the output via a resistor of 30 kΩ
4	GND	**Ground**; connected to rear of chip
5	D	**Reset Delay**; connect with capacitor to GND for setting delay
6	E6	**Hold**; see truth table above for function; this input is connected to output voltage across puliup resistor of 50 kΩ
7	Q	**5-V Output**; block to GND with 22-μF capacitor, ESR < 3 Ω

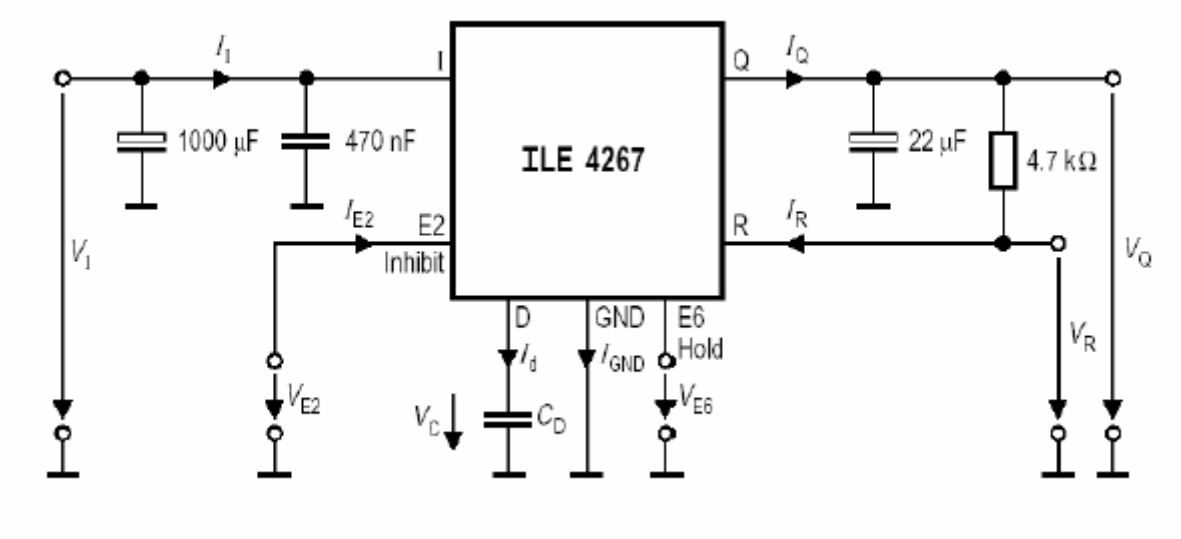
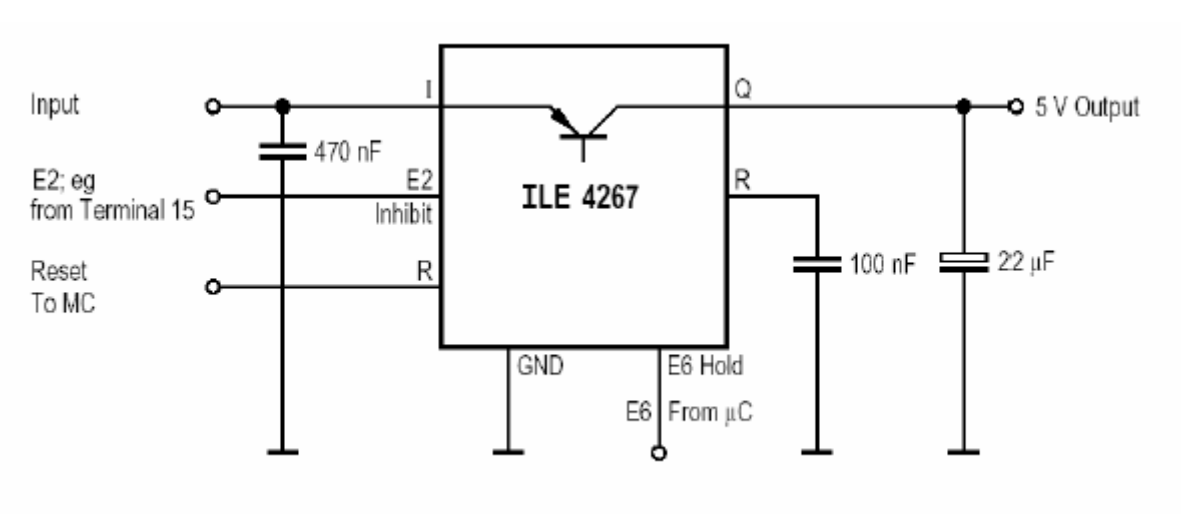
Turn-ON hysteresis	ΔVi, ov	2	-	6	V	-

1) The reset output is Low between V_Q = 1 V and V_{RT}

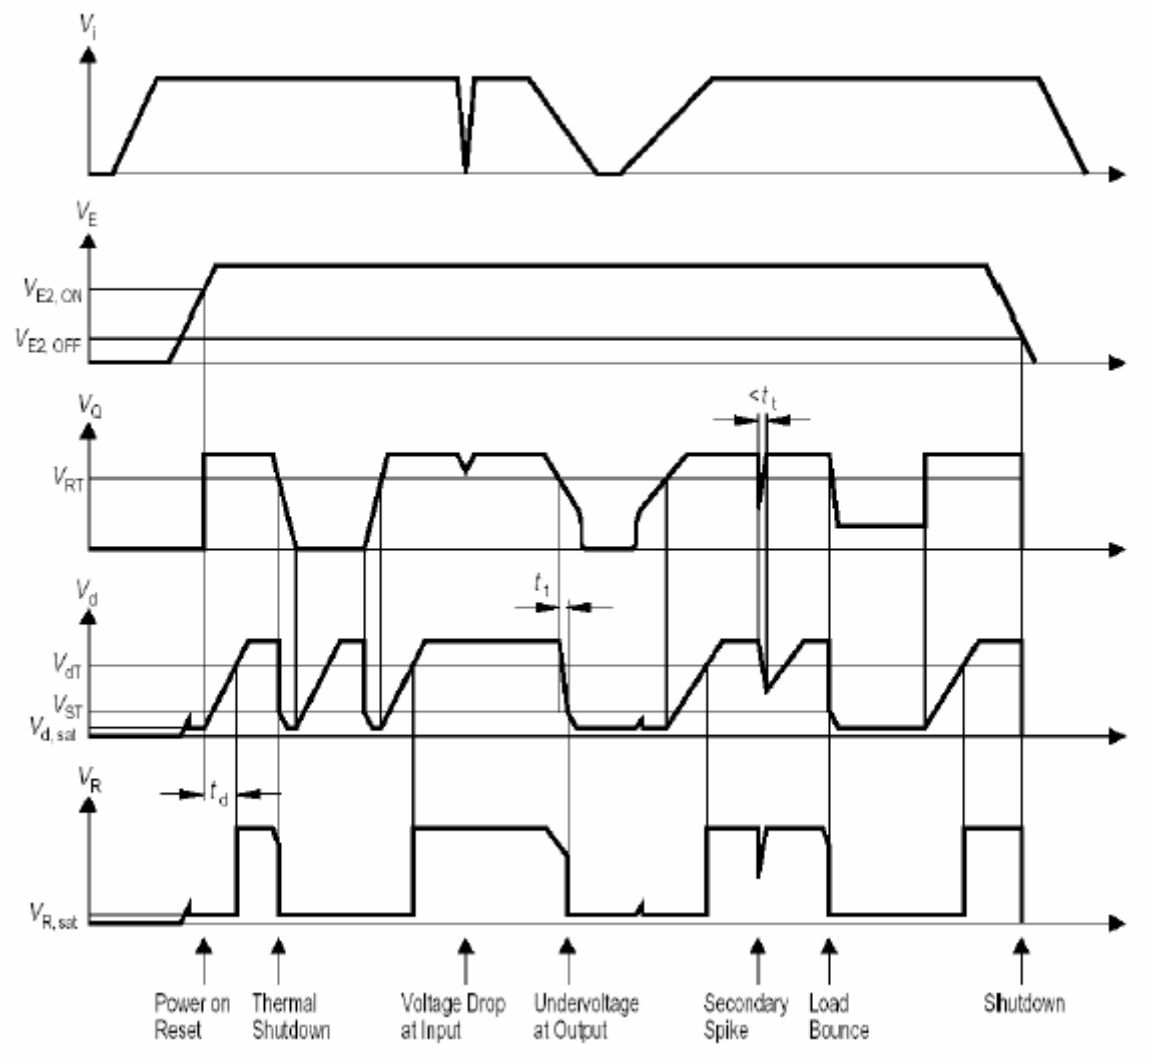
Test Circuit



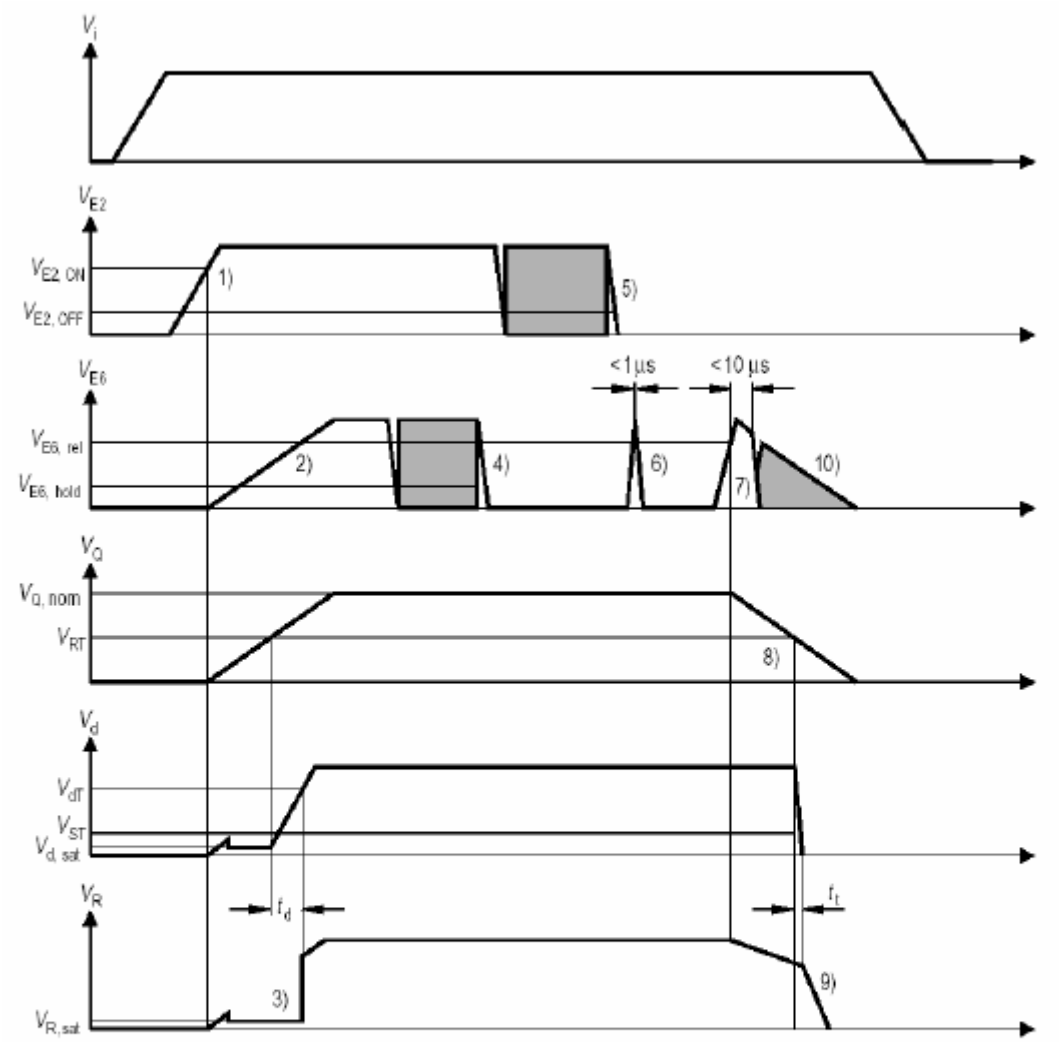
Application Circuit



Time Response



Enable and Hold Behaviour



1) Enable active
2) Hold inactive, pulled up by V_Q
3) Power-ON reset
4) Hold active, clamped to GND by external µC
5) Enable inactive, clamped by int. pull-down resistor
6) Pulse width smaller than 1 µs
7) Hold inactive, released by µC
8) Voltage controller shutdown
9) Output-low reset
10) No switch on via V_{E6} possible after E6 was released to $V_{E6} > V_{E6, rel}$ for more than 4 µs
