AN3240
Application note

Ultrasound HV pulser demonstration board

Introduction

This application note describes all the possible demo applications helpful in carrying out a full evaluation of STHV748 functions.

The STHV748 high-voltage, high-speed pulser generator features four independent channels. It is designed for medical ultrasound applications, but can also be used for other piezoelectric, capacitive, or MEMS transducers.

The device contains a controller logic interface circuit, level translators, MOSFET gate drivers, noise blocking diodes, and high-power P-channel and N-channel MOSFETs as output stages for each channel. There is also a clamping-to-ground circuitry, anti-leakage, an anti-memory effect block, a thermal sensor, and a HV receiver switch (HVR_SW), which guarantees a strong decoupling during the transmission phase.

Moreover, the STHV748 includes self-biasing and thermal shutdown blocks (see block diagram in *Figure 1*). Each channel can support up to five active output levels with two half bridges. The output stage of each channel is able to provide ±2 A peak output current. In order to reduce power dissipation during continuous wave mode, the peak current is limited to 0.6 A (a dedicated half bridge is used).

3 STHV748 PCB demo description

The STHV748 PCB demo can drive four transducers as 4-channel transmitters/receivers for ultrasound and other applications. The demo board consists of one STHV748 in a 64-lead 9x9x1 mm QFN package.

The STHV748 can deliver up to a ±2.0 A source and sink current to a capacitive transducer. It is designed for medical ultrasound imaging and ultrasound material NDT applications.

The STHV748 output waveforms can be displayed directly for each channel Ch A/B/C/D using an oscilloscope by connecting the scope probe to the J1, J2, J3, and J4 jumpers, moreover, the user can select whether or not to connect the onboard equivalent load, a 300 pF 200 V capacitor paralleled with a 100 Ω, 2 W resistor (or alternatively, 200 Ω//50 pF - 200 Ω//250 pF - no-load). A coaxial cable can also be used to easily connect the user transducer.

IN1/2/3/4, for each channel available in IC, is controlled via the 13 pins of the C1 (CONN1) head connector on the board (34 pins).

The main issues in this PCB design are the capacitance values, to ensure good filtering and an effective decoupling between the low voltage inputs (IN1, IN2, IN3, IN4, and EN for each channel) and the HV switching signals (XDCR, HVOUT, etc.,) which is ensured by the layer separation used.

HVM1:TX1 high voltage negative supply, (B4 conn.)

HVP1:TX1 High voltage positive supply, (B2 conn.)

5.1 Load selection

It is possible to select the following load configuration for each channel (ChA/B/C/D) using J1, J2, J3, and J4:

- 100 Ω // 300 pF
- 200 Ω // 50 pF
- 200 Ω // 250 pF
- No-load

Figure 6. Load configuration schematic
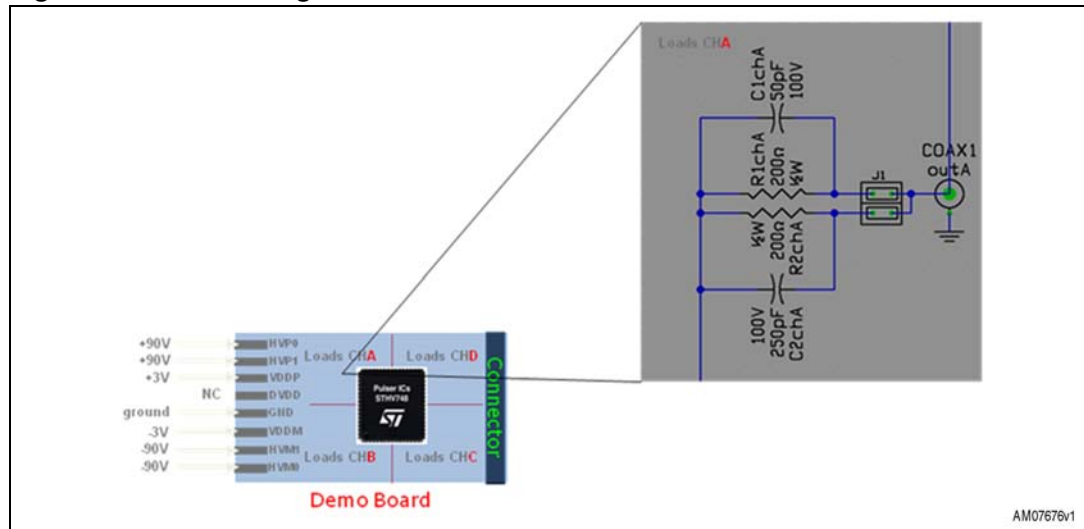

5.2 Fixed STHV748 pins on PCB demo

In order to clarify some special pin behavior, a short explanation is given:

EN allows the minimizing of the power consumption. If EN=0, the self-voltage reference is not supplied. By supplying the reference externally, the total power consumption is reduced.

THSD is a thermal flag. The output stage of the THSD pin is a Nch-MOS open-drain, so it is necessary to connect the external pull-up resistance (R2≥10 kΩ) to the positive low-voltage supply (see *Figure 2*). If the internal temperature surpasses 160 °C, THSD goes down and puts all the channels into HZ state. By externally forcing THSD to a positive low-voltage supply, the thermal protection is disabled.

D_CTR can be used to optimize 2nd HD performance by tuning the fall propagation delay (TDF - see the datasheet, STHV748; *5-level, ±90 V, 2 A high speed pulser with four independent channels*). If D_CTR is equal to ground, TDF has the nominal value. If D_CTR is being varied from 2 V to 4.2 V, TDF can be changed from -1 ns to +600 ps, with respect to the nominal value.

EXPOSED-PAD is internally connected to the substrate. It can be floating or connected to a 100 V capacitance toward ground, in order to reduce noise during the receiving phase. The fixed configuration of the PCB application pins described is given in *Table 8*.

Table 8.   Special pin connections

Special pins on the PCB demo		
Name	**Description**	**Status on board**
EN 64-pin	Enable pin With EN=1, the IC internally generates the reference voltages on REF_HVP1/0 (7, 10, 39, 42-pin) and REF_HVM1/0 (2, 15, 34, 47-pin). These voltages are set VDDP below HVP and VDDP above HVM, respectively: REF_HVM# = HVM# + VDDP REF_HVP# = HVP# - VDDP When EN=0, it is required that an external voltage is applied to REF_HVM# and REF_HVP# pins (see the STHV748 datasheet).	Active – forced to 3 V through R1=10 kΩ
THSD 32-pin	Thermal shutdown pin	Active – forced to 3 V through R2=10 kΩ. The user can monitor the THSD status on TP1 (test point)
D_CTR 16-pin	Delay control pin	Not active – forced directly to ground
EXPOSED-PAD	Substrate	Not active – connected to ground through Cs1=0.22 µF

6 Demonstration kit composition

There are essentially 3 methods to drive the STHV748 demo board, for each of them the user must connect a custom PCB adapter, via the C1 connector, to drive the IC pulser.

6.1 Method 1 (flexible - based on BNC PCB adapter)

In this case, the demo board, described in *Section 3*, is being connected up, via the C1 connector, to a custom PCB adapter with 8 BNC connectors. A couple of BNC are dedicated to IN1 and IN2 for each channel and usable for the external waveforms generator. In addition, 2 switches are dedicated to connecting IN3 and IN4 to 0V or VDD, in accordance with the truth table (see *Table 2* and *Figure 8*). The composition of the demonstration kit is shown in *Figure 7* and *9*.

Figure 7. Demonstration kit composition (PCB demo plus BNC PCB adapter)
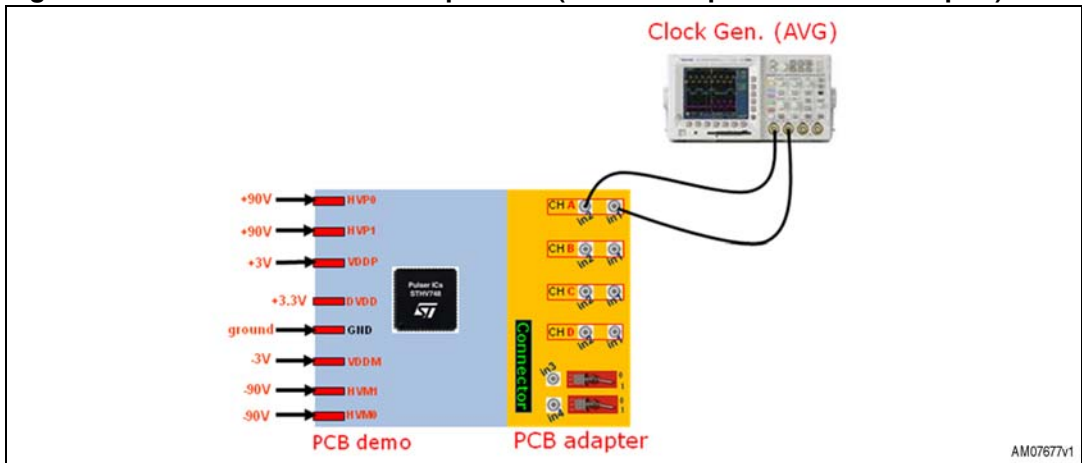

Figure 8. PCB adapter image, top layout and top schematic
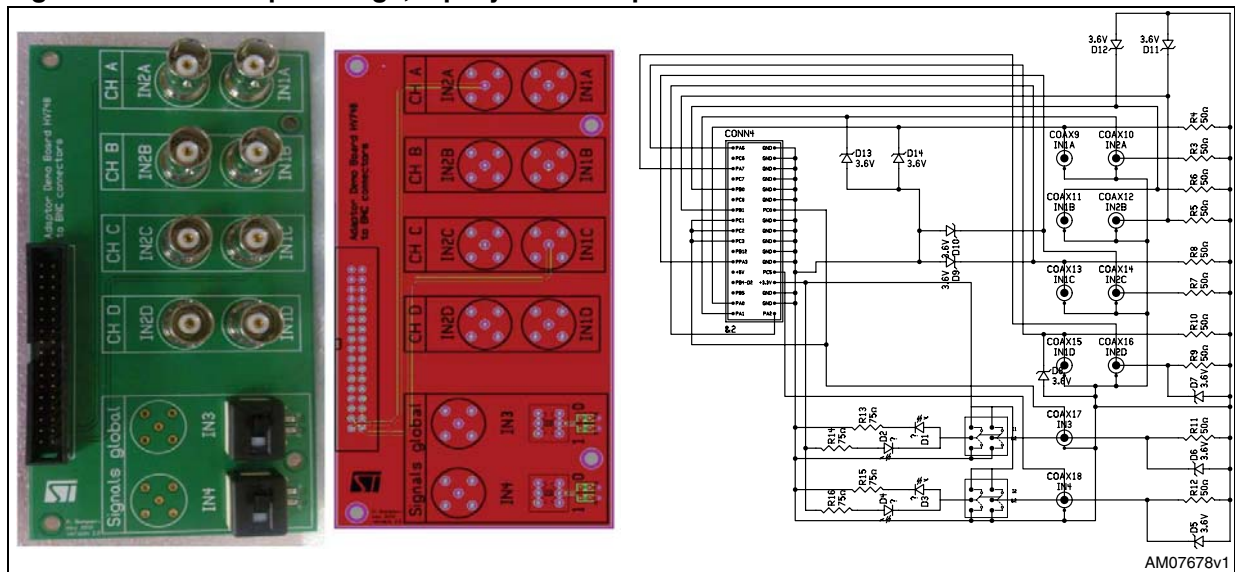

**Figure 9.   Demonstration kit system image**

AM07679v1

6.1.1   How to drive the STHV748 for method 1

The user simply needs a clock generator (or an AVG) in a way to drive pins IN1 and IN2 with a proper time pulse width, consequently, it is possible to fix a truth table state for XDCR using the 2 switches on the PCB adapter connected to VDD supply or GND, which control IN3 and IN4. See the example diagram below (*Figure 10*):

Figure 10.   Inputs set of generators for PW mode (4 cycles - TX0 pulser Chx)
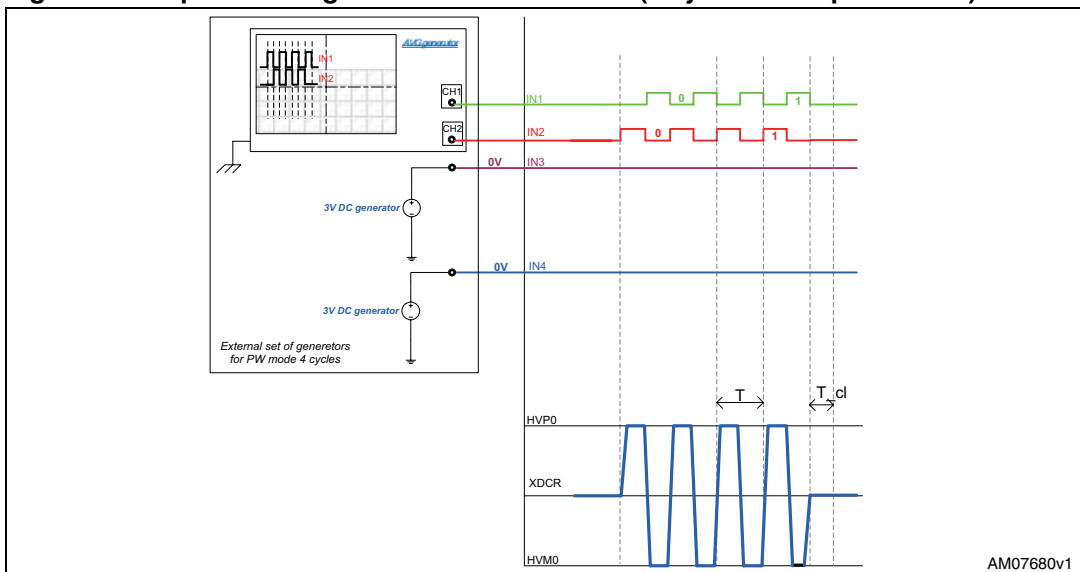

AM07680v1

Note: *The DC generators, shown in Figure 10, are symbolic, in the truth table the VDD voltage is selected by the user through the J9 jumper on the PCB demo, which supplies the switches on the PCB adapter.*

In *Figure 10*, an example of a TX0 pulser in PW mode setting, is described. It is possible to pass easily to a TX1 pulser PW mode in the same example shown in *Figure 10*, in fact, it is enough to change the IN3 status, through the switch on the PCB adapter, from 0 to VDD (IN4=0 - not touched). This simple commutation on switch IN3 allows 4 cycles for the TX1 pulser.

In the same manner the user fixes the other states, such as CW mode (IN3=VDD, IN4=VDD) or MaxHV0 and HV1 mode (IN3=0, IN4=VDD), by just changing the switch position on the PCB adapter.

The status of switches IN3 and IN4 is being monitored by two SMD LED diodes, for each switch, on the PCB adapter (D1 red and D2 green close to IN3, D3 red and D4 green close to IN4).

As shown in *Figure 11*, the red light near the switch indicates state 1 (when VDD voltage is active, the switch button is in the left position) while the green light indicates state 0 (when 0 is active, the switch button is in the right position).

Figure 11. Diodes LED status on the PCB adapter which indicates IN4=1 and IN3=0
When the switch button is in the center position the status is on HZ.

6.2 Method 2 (use of the motherboard based on the STM3210E-EVAL)

The demo kit, in this solution, is made up of a motherboard based on the STM3210E-EVAL plus the PCB demo mentioned into *Section 3* (see *Figure 12*). It doesn't require any manual driving because the STM3210E-EVAL microcontroller is programmed to deliver some demo patterns.

**Figure 12. Demonstration kit based on the STM3210E-EVAL system**

Figure 13.   Demonstration kit based on the STM3210E-EVAL system image

6.2.1   Motherboard communication setting

The STM3210E-EVAL system communicates with the PCB demo through the C1 connector, following the signal setting represented in *Figure 14*.

**Figure 14.   STM3210E-EVAL pin connection**

6.2.2 Motherboard driving performance for the PCB demo

The STM3210E-EVAL demonstration board (motherboard) has been programmed to show the STHV748's main functions. In particular, the firmware installed into the internal memory allows the PCB demo to be driven in a way that the STHV748 pulser performs an example of three work conditions:

● Pulse wave mode (PW), (see *Figure 15*)

● Continuous wave mode (CW), (see *Figure 16*)

● Pulse cancellation mode (PC), (see *Figure 17*)

Figure 15. PW mode functions

**Figure 16.   CW mode functions**

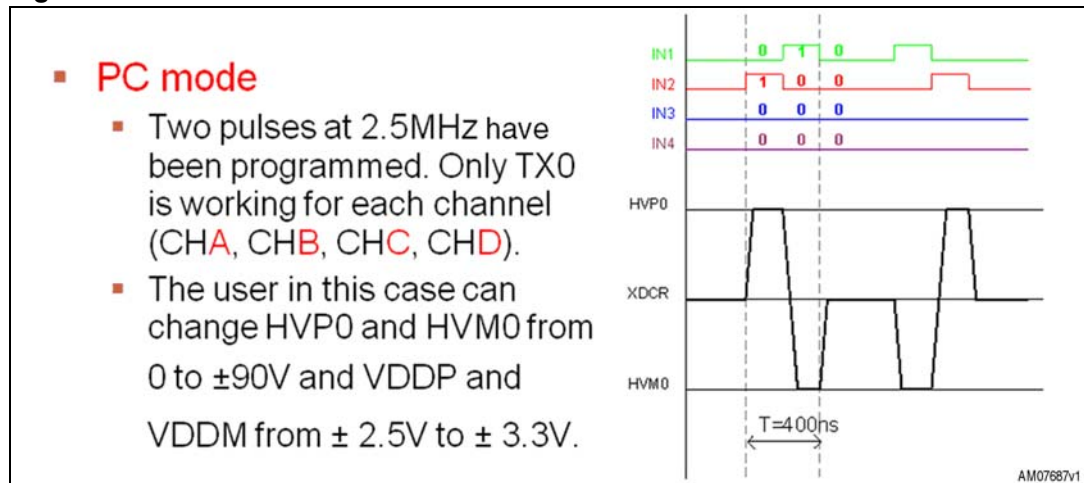

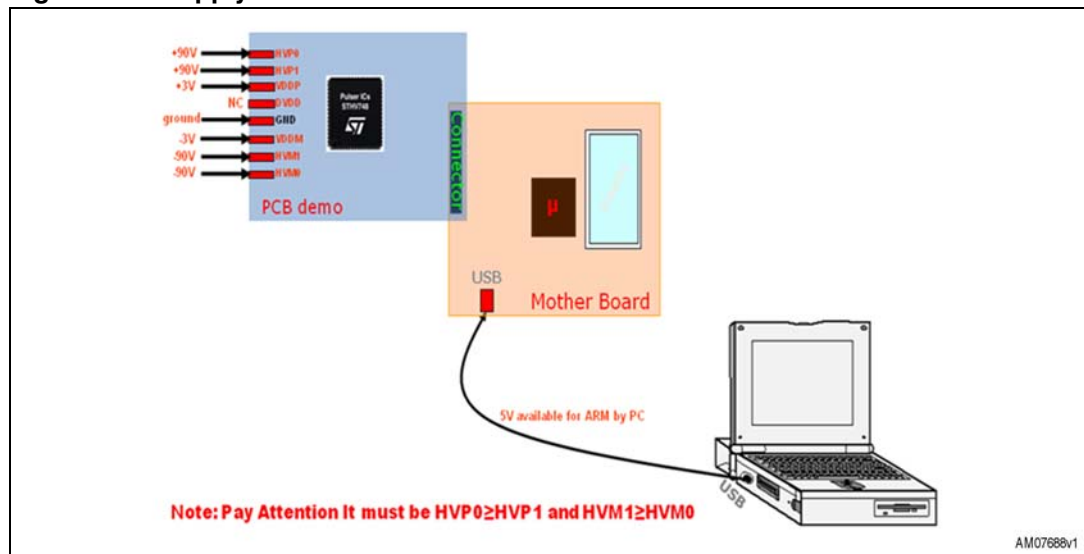

Figure 17.   PC mode functions

Figure 18.   Supply connection for demonstration kit with the STM3210E-EVAL

6.2.3 Turn on demo system

1. First step:

Connect all supplies as indicated in *Figure 18* based on the following power up sequence (see *Table 7*):

– 1st USB connection (power supply for the motherboard and digital supply DVDD for the STHV748)

– 2nd analog low voltage connections for the daughter board (VDDP=+3 V, VDDM=-3 V)

– 3rd high voltage power supply connections for the daughter board (HVP0/1=+90 V, HVM0/1=-90 V)

2. Second step:

– After the power supply connections, the onboard display appears as follows (*Figure 19*):

Figure 19. Main menu on STM3210E-EVAL display
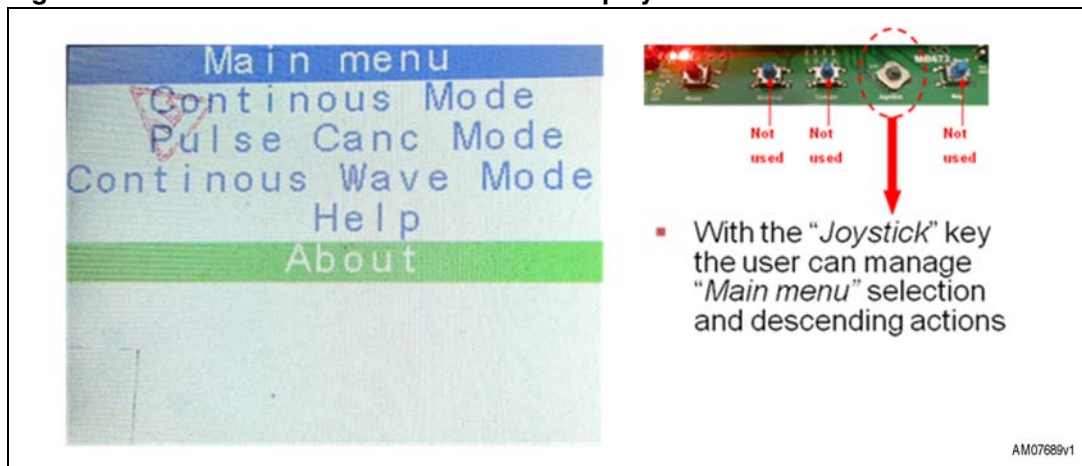

3. Third step:

– By moving the "Joystick" key up and down the user can select one of the three modes available (PW, CW or PC mode) in the "Main menu". When the user has selected a mode the Joystick key must be pressed to descend into the mode menu (see *Figure 20*).

**Figure 20.   Main menu selection on the STM3210E-EVAL display**
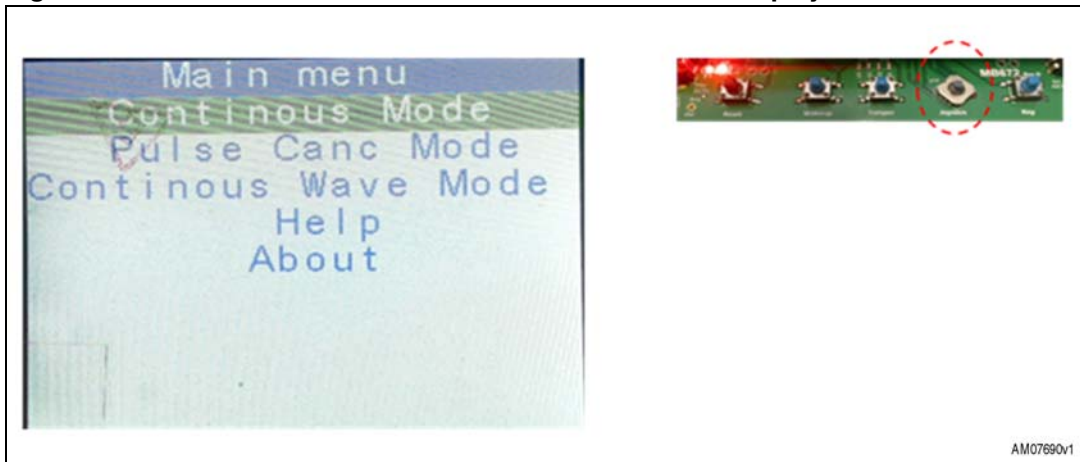

–   Assuming that the user has descended into the "Continuous Mode" menu, it is possible to manage the PW mode. In fact, by moving the Joystick key "Generate Signals" can be selected (see *Figure 21*). The Joystick key must now be pressed to run the PW mode function. If the user wants to change the choice, it is enough to select and press "Return" to go to the main menu and choose another function, such as CW or PC.

Figure 21.   Example of "Continuous Mode" selection on the STM3210E-EVAL display

–   After having run the mode, the user can stop the "Continuous Mode" and return to the previous menu just by pressing the Joystick key on the board (see *Figure 22*).

**Figure 22. Exit the mode selected on the STM3210E-EVAL display**
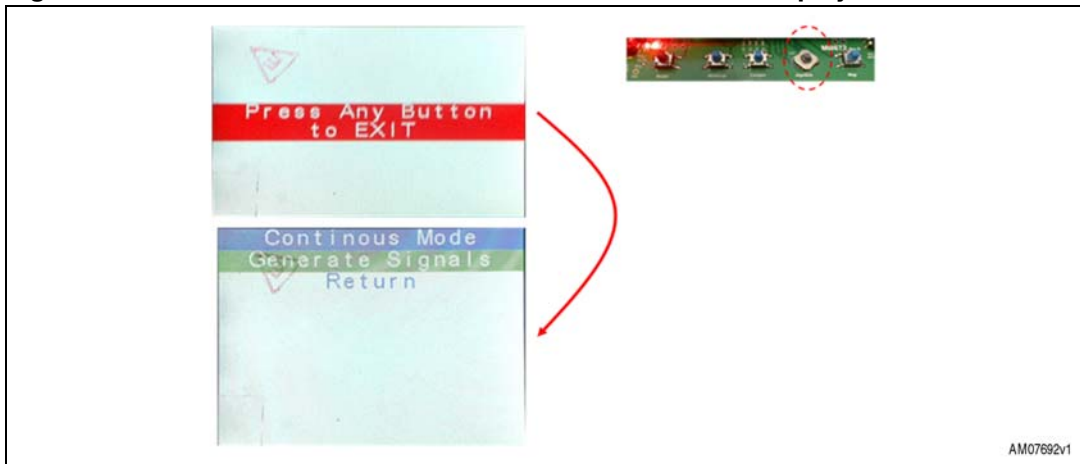

6.2.4 Turn off demo system

4. Fourth step

Demo off can be executed by following the power down sequence:

– 1st high voltage power off (HVP0/1=+90 V, HVM0/1=-90 V)
– 2nd low voltage power off (VDDP=+3 V, VDDM=-3 V)
– 3rd unplug the USB connection (power off supply for the motherboard)

Figure 23. Reset key on the STM3210E-EVAL

6.2.5 Acquisition examples of PW, CW and PC mode

**Figure 24. PW mode (HVP0=60 V HVM0=-60 V 100 Ω//300 pF)**

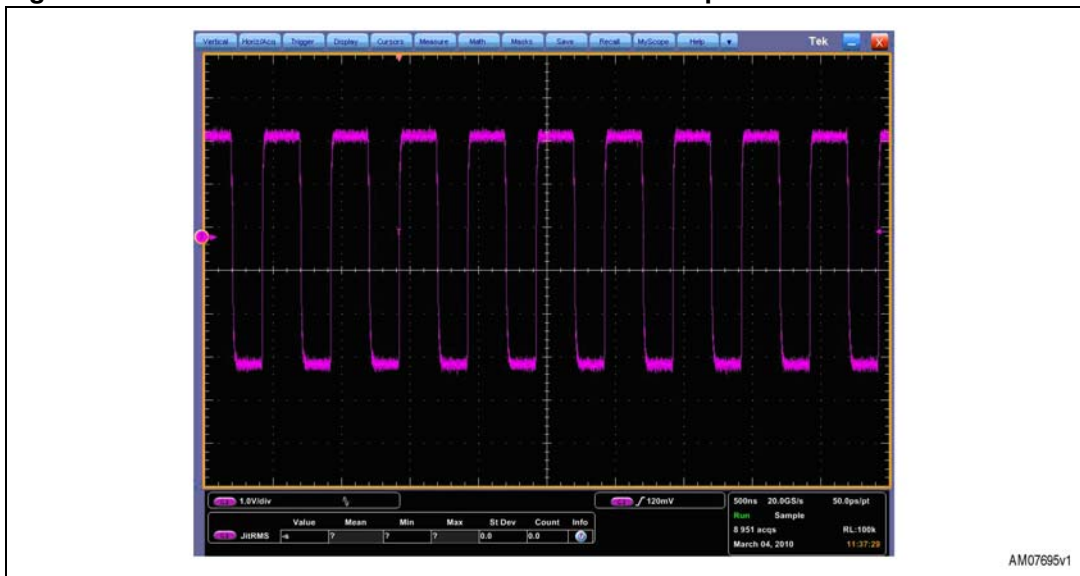

Figure 25. CW mode HVP1=5 V HVM1=-5 V 100 Ω//300 pF

**Figure 26. CW mode HVP1=10 V HVM1=-10 V 100 Ω//300 pF**

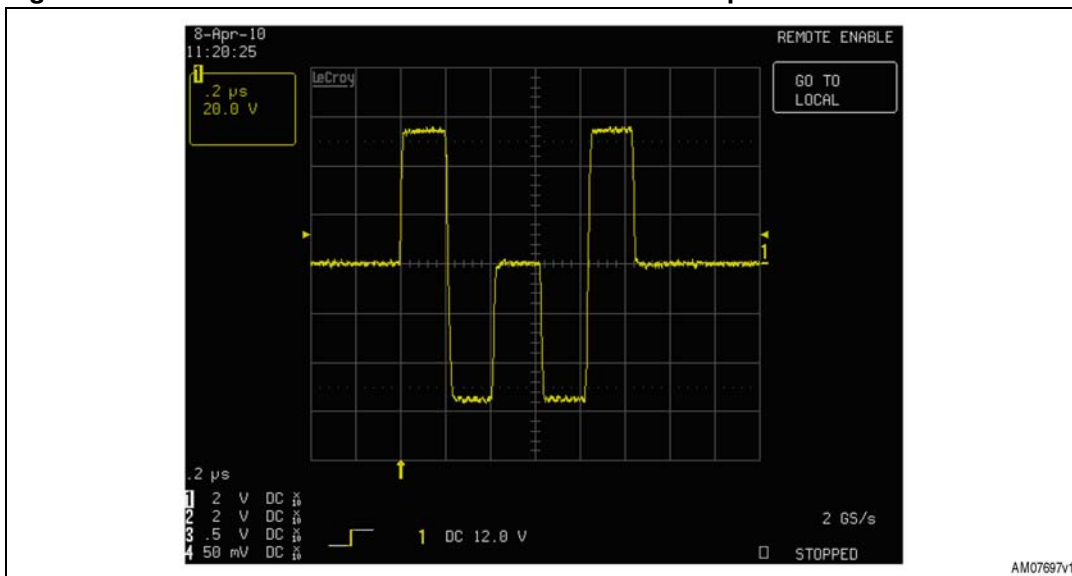

Figure 27. PC mode HVP0=60 V HVM0=-60 V 100 Ω//300 pF

6.3 Method 3 (LabView interface - use of the HSDIO PCB connector)

The user, who has the possibility of using LabView equipment, as shown in *Figure 28*, can evaluate the STHV748 detailed functions.

Figure 28. LabView equipment used to develop the STHV749

In this case, customized software has been developed (STHV748.vi) to manage all channels in such a way as to test them in several working conditions (see the PC display - *Figure 29*).

In the case of the user having the LabView chain, previously mentioned, it's possible to connect the PCB demo to the LabView system through a PCB connector shown in *Figure 30*.
